Since its inception, the Division of Health and Fitness has vigorously prosecuted these concepts as they were originally visualized by the Board of Trustees and the Director of the Bureau of Health Education. Over the years, however, the functions and operations of the Division gradually grew in scope and direction until lately they have been largely concerned with youth fitness as this can be implemented through cooperation with the schools and agencies concerned with the health of school-age children.

Within the last two years there has been renewed interest in fitness, and especially youth fitness, on the part of the federal government. This interest, stimulated by the personal concern of President Eisenhower, has helped to create a climate for action which has enhanced the efforts and advanced the work of the Division. Also, it has shown the wisdom of the 1946 action of the then Board of Trustees and put the Association in a position of leadership in the national present campaign to improve the fitness of youth.

The Health and Fitness Division now staffed by three consultants, Donald A. Dukelow, M.D., Fred V. Hein, Ph.D. and Wallace Ann Wesley, Hs.D., functions as an integral part of the Bureau of Health Education. Consultative services on the medical and educational aspects of health and fitness and particularly policies, practices and problems in school health are offered by this physician and educator team to state and local medical societies, voluntary and governmental agencies in education and public health, colleges and universities, and others concerned with the health of school-aged children.

During the past year the three consultants accepted invitations in 29 states, the District of Columbia and Canada to deliver 99 addresses and to take part in 113 conferences, institutes, annual meetings, and conventions of health education or other organizations and to perform a variety of other services. In nearly every instance, such engagements included several assignments. Altogether the consultants' travel covered 110,720 miles. Demand for consultant services relating to the health and/or fitness of youth has steadily increased until it has become necessary to decline many invitations each year because of travel and time limitations of the staff.

The Sixth National Conference on Physicians and Schools, sponsored by the American Medical Association, was held October 30 to November 2, 1957, under the auspices of the Bureau of Health Education at the Hotel Moraine, Highland Park, Illinois. Fittingly, with the biennial conferences extending over a ten-year period, the theme of the Sixth Conference was "A Decade of Progress Toward Fitness." As was true of the five previous conferences, the Sixth National Conference was an invitational affair. Attending were over 200 representatives of state and territorial medical associations, health departments, education departments, and delegates from a number of national voluntary and governmental health and educational agencies. More than eighty consultants drawn from the professions of medicine, education and public health served as leaders for ten discussion groups concerned directly or indirectly with relationships of the physician to the school health program.

The National Conferences on Physicians and Schools have stimulated many state and local conferences of a similar nature covering school health. The consultants have participated in planning and conducting many of these meetings, and within the limits of available time, their services are available to state associations for such purposes. In this connection, the consultants conducted a limited normative survey of state medical society activities in the field of school health. A previous report covering the same areas of endeavor was published in October, 1955, under the title, "Survey Report of School Health Activities of State Medical Associations." The new survey, based on information supplied by the State Medical Associations, brought the earlier report up to date and summarized recent efforts by constituent state societies in the field of school health.

The medical consultant (Dukelow) completed the first year of his term as a member of the Joint Committee on Health Problems in Education of the National Education and the American Medical Associations with the annual meeting held in March 1958. During this year he has served in the capacity of Secretary to the Committee and was re-elected to the same position. All three consultants provide assistance to the Joint Committee in a number of ways and particularly as technical assistants to the several subcommittees concerned with Joint Committee projects and publications.

One of the educational consultants (Hein) is now serving as the staff secretary for the Association's new Committee on Injury in Sports. This Committee has been active in cooperating with appropriate athletic groups in attempting to safeguard the health and welfare of participants. The same consultant also serves the Board of Trustees' Special Committee on Amphetamines and Athletes in a smilar secretarial capacity.

The medical consultant (Dukelow) serves as a consultant to the Association Committee on Relationships between Medicine and Allied Health Agencies and as liaison between the Committee and the Bureau of Health Education. He also continues to be Health Education Consultant to two committees of the Council on Medical Service—the Committee on Medical Care of the Industrial Worker and the Committee on Maternal and Child Care. All three of these involve interprofessional and inter-agency relations with many medical and public health organizations.

During the current year, as in the past, the Consultants in Health and Fitness have assisted the Bureau Director in the preparation of several transcription series and other radio and television programs. This involves aid in developing ideas, gathering appropriate materials, review of scripts to determine their scientific accuracy and educational implications, and on appropriate occasions, serving as consultants or participants at the time of production.

Health education films and film strips, particularly those used for visual education in the schools, are important educational media. The consultants have advised on the production of films and film strips for classroom instruction in health subjects. In addition, within limitations, they review films for health education of the public and those used for classroom instruction in health to determine their technical accuracy and applicability. In certain instances, the consultants make use of appropriate films from the library of the Committee on Medical Motion Pictures in connection with their Association responsibilities in the field.

Considerable consultant time is given to conferences, meetings, and institutes conducted by universities, teachers' colleges, municipal boards of education, state departments of health and education and other agencies to improve understanding of school health services, school health education and healthful school living and fitness programs. These in-service education projects vary in length from two days to two weeks and are attended by teachers, school administrators, college faculty members, parents, physicians, dentists, nurses, and others concerned with child health.

For the 12th year, the Consultants have prepared discussion questions on the articles in *Today's Health* to aid teachers in using the Association's health magazine as classroom health education material. The questions are developed for each issue, published during the school year, and sent to all interested schools subscribing to *Today's Health.*

Bureau Publications

Pamphlet Production and General Printing.—The Bureau now carries 422 (383) health education pamphlets as regular A. M. A. stock in addition to offering 46 (44) Reading Lists. (Last year's figures are in parentheses.) During the year we added 56 (43) new titles—42 of which were reprinted from *Today's Health:* 5 (0) from THE JOURNAL, and 9 (3) of which were specially written.

Additional printings to replenish the stock were ordered for 44 (43) titles, and 12 (47) titles were discontinued. Four (6) additional *Today's Health* articles were reprinted for the authors or others but not put into A. M. A. stock (See Exhibit A.) Thirteen reprints required special handling because of orders varying from 500 to 5,000 in quantity.

In addition to the pamphlets we had printed 3 (4) new promotion folders for our electrically transcribed radio series, an announcement folder for "The Health Magazine of the Air," radio series and 2 (2) inserts for the Televisuals booklet.

As a service to the Committee on Alcoholism of the A. M. A. Council on Mental Health we compiled their recent series of articles, did the layout and handled the production and printing of "The Manual on Alcoholism."

Meetings and Conferences

The Bureau staff traveled 175,848 (129,881) miles to attend meetings or address audiences in 29 (32) states, the District of Columbia, Canada, and London, England. Audiences numbered 154 (100) and totaled 25,307 (18,652) persons.

Cooperative Relationships

The Director serves as an official representative of the American Medical Association on the seven committees.

United States Government Agencies.—The Bureau continues to cooperate by correspondence or otherwise with government agencies. Materials or information have been furnished during the past year to the 20 government agencies.

Joint Committee on Health Problems in Education, A. M. A.-N. E. A.

On March 10, 11, and 12, 1958 the Joint Committee met in the Conference Room of the National Education Association in Washington, D. C. It meets in the offices of the parent organizations alternately. Since its creation in 1911 the Joint Committee's chief functions have been to give interprofessional consideration to principles and policies affecting the health of children and youth of school age. The Committee's opinion is disseminated through publications distributed by both the National Education Association and the American Medical Association.

BUREAU OF MEDICAL ECONOMIC RESEARCH

The period covered by this annual report is from July 1, 1957, to June 30, 1958. Because the distribution of the Bureau's activities during the past year differed considerably from those of previous years, the organization of this annual report will deviate from reports of previous years.

For the past several years the problem of research associates has loomed large. For two intervals of nine months during the past three years, there was only one research associate on the staff. The first of those two periods ended July 1, 1957 with the employment of Walter Polner, Ph.D. A few months later he was loaned to the Forand Bill Staff Task Force as a full time research associate and has not been available for Bureau research undertakings. In that capacity he prepared articles for the Chronic Illness Newsletter of the Council on Medical Service, an editorial which was used by the Council on National Defense, and had finished three other manuscripts by July 1, 1958. The second period ended on July 1, 1958, when Vaughn D. Bornet, Ph.D., joined the staff as a research associate, although Dr. Polner continues on special assignment outside the Bureau.

The Director has continued to serve on the Advisory Committee to the U. S. Bureau of Labor Statistics on the consumer and wholesale price indexes. Elizabeth Langford of the Bureau of Labor Statistics prepared an article entitled, "Medical Care in the Consumer Price Index, 1936-56," which appeared in the Monthly Labor Review (U. S. Department of Labor, September, 1957). This article pointed out the same general trends as a number of our Bureau publications, namely, that for the entire inflationary period starting about 1940, the subindex based on the sample of physicians' fees priced by the Bureau of Labor Statistics has not risen nearly as rapidly as the entire Consumer Price Index. In the past the Director has waited until fall in order to cover both the price indexes and personal consumption expenditures for medical care; the latter are compiled by the U. S. Department of Commerce and are not usually available until late August. The Director regrets that at the present writing there is no clear indication on the choice of a new base period; it could be 1960 or 1958 or a three year period. It appears likely that for some years to come we shall be faced with the criticism of the high indexes for physicians' fees which is a mirage due to the use of 1947-1949 as a base period. Many inquiries are received from physicians requesting income data on the profession. The Bureau and the United States Department of Commerce joined hands in making a definitive survey of physicians' incomes for 1949. Except for a very small sample study for 1951 under joint sponsorship, neither sponsor has made a study for a later year.

During the year the Director and Leonard W. Martin, Ph.D., Research Associate, addressed medical and lay groups. An article by the Director on the Australia study was published in a political science research journal; an article entitled, "Free Enterprise—Why?" by Dr. Martin was published in the June, 1958, issue of *The Freeman.*

The Director's interest in the Jenkins-Keogh bills has continued, although the active work on the bills is largely performed by the staff of the American Thrift Assembly of which the American Medical Association is a member. Some of the organizations supporting these bills which are not members of the American Thrift Assembly have been in touch with the Director because of his long-time work on these bills. The Bureau has printed 27 items on these bills during the last eight years. Consideration has been given to a number of suggested changes in the limits on the annual amounts set aside which might improve public and congressional support of these bills. (On July 29 the House passed the bill by a voice vote with little opposition.)

Steady progress has been made in the task of editing, coding, and anlyzing the data on 400,000 inpatients discharged from 6,000 hospitals. During the year the office of the Standard Nomenclature of Diseases and Operations has developed 225 categories into which all of the more than 15,000 separate diagnostic codes can be grouped. This work has modified the original research program and involves considerable experimentation with our data, particularly those from the New England hospitals. At the present writing it seems likely that these 225 groups can be established experimentally and can be made available as a part of future editions of the Standard Nomenclature. It will become a more useful publication to physicians and statisticians. The IBM operations for all of the 6,000 hospitals should be completed early in 1959. As an incidental part of this research project the Bureau was able to furnish the Staff Task Force on the Forand Bill new data on the comparative duration of average stay in New England hospitals by age groups, particularly for the age group 65 and over. The Director continues to regard this basic research study as one of the most valuable ever undertaken by the Bureau. When completed it will be possible to tell the American people what they get for what they spend for medical care in terms of their ailments.

Several annual reports of the Bureau prior to that for 1957 made extensive reference to IBM operations as the IBM division was part of the Bureau for many years. Several references were made to the statistical card and uses being made of that deck. This statistical card, which was utilized to help prepare the 1958 American Medical Directory, will now be made available to the Bureau in a reproduced deck. It will be an important tool in the research program of the Bureau—women physicians, distribution of medical school alumni, rising proportion of physicians not in active private practice, proportion of services given by physicians without charge, etc.

In Bulletin 104, Accident Burden on Hospitals, we found that accidents account for 7 to 8% of the utilization of hospitals and, presumably, of the services of physicians. During 1955 accident patients accounted for more than $300,000,000 of hospital expenditures. Almost one third of the emergency room service was to the victims of accidents. Prevention of accidents is a responsibility of all citizens, not of physicians alone. It is important to note that accidents and pregnancies, neither of which is a disease, account for about one fourth of the inpatients discharged from hospitals. Our exhibit at the annual meeting in San Francisco was a series of charts on the accident burden on hospitals reproduced in Bulletin 104A. In the 1958 edition of *Accident Facts*, a widely used publication of the National Safety Council, the first text page was devoted to a summary of our study of the accident burden on hospitals. Thus the presentation of the results of our research is being publicized by the National Safety Council. This illustrates one of the problems which the Director has never been able to solve to his satisfaction, namely, communicating the results of the Bureau's research to members of the public. It is recognized that an agency such as the National Safety Council may actually reach many sections of the American public much more efficiently than could any type of popular pamphlet published by the Bureau.

Bulletin 105, The Younging of Electorates, is a very condensed report of the Director's findings during his four month study in New Zealand and Australia early in 1957. Based upon an examination of many documents not available in the United States and interviews and conferences with more than three score academic, religious, journalistic and political leaders of the two countries as well as independent study before, during, and after the visit, he found: (1) After about a half century during which the proportion of voters 50 years of age and over has been increasing, the proportion of older voters will start to decline in Australia after 1961, in New Zealand after 1962, in France (slowly) after 1965, and in the United States after 1970; the proportion of older voters will still be rising in the United Kingdom in 1978, the last year for which estimates could be prepared of the number of voters 21 years of age and over without hazarding a prediction of the number of births in each of these countries during 1958 and subsequent years. (2) There was considerable evidence that the increasing proportion of older voters in Australia, and to a lesser extent in New Zealand, was an important factor in developing a strong trend toward the Welfare State in recent decades. The Director's general thesis is rather new and, of course, it will be several years before social scientists in the various countries will test his basic thesis of the rise and fall of the Welfare State. The Director is happy to report that Bulletin 105 has established many new contacts for the Bureau of Medical Economic Research with universities in the United States and other countries. The Director earnestly hopes that this type of study may be of use to the Association in the discussion of important policies during the next decade and that it will reduce some of the criticism heaped upon the medical profession for its great success in prolonging life during this century and enabling so many people to live on into old age, when their understandable demand for security guaranteed by government generates increasing political pressure for a riskless society. (3) As Australia approaches the end of the period of its aging electorate and moves into the new era of the younging of its electorate, there are manifold evidences that the citizens of this continent "down under" will move away from some of the Welfare State ideas.

The mystery of why females live longer than males was given a new turn in a Bureau publication during the year (M-111).

In another editorial in THE JOURNAL (June 14, 1958, reprinted as M-113), the Director summarized an important study showing that one of the basic reasons why people, particularly those in the low income groups, bought life insurance was to provide a clean-up fund to pay off medical and other bills at death. Over one billion dollars annually is paid out by life insurance companies in death claims for persons age 65 and over and this considerable sum of money should not be disregarded in any consideration of funds available to pay the costs of the last illness for retired persons.

REPORT OF BUSINESS MANAGER

During the past year, the handling of the business activities of the Association has continued to improve. During the first seven months of this period, Thomas R. Gardiner handled the combined responsibilities of Business and Advertising Manager. On Feb. 1st, after 49 years of service with the Association, Mr. Gardiner retired as Business Manager, and Russell H. Clark assumed the responsibilties of Business Manager, and Robert J. Lyon assumed the responsibilities of Advertising Manager. Shortly thereafter, the business activities of the Association were reorganized under eight headings: Accounting, Personnel, Contract Printing, Advertising, Records and Circulation, Operating Services, Convention Services, Building Maintenance. The Business Department continues in its role of service to all of the other Headquarters activities.

During the year July 1, 1957, to June 30, 1958, the plans for remodeling and air-conditioning the Association's Headquarters Building in Chicago were completed and a program to implement these plans was submitted to, and approved by, the Board of Trustees. These plans envision an investment by the Association of approximately two and a half million dollars, and when completed in December, 1959, will provide the Association with a Headquarters building ideally suited to the needs of the Association for many years to come. An integral part of the program calls for renovating the first three floors of the building which in years past had been occupied by the A. M.A.'s printing plant.

RECORDS AND CIRCULATION DEPARTMENT

Membership Records

The Fiscal Year July 1, 1957 Through June 30, 1958

The number of physicians holding membership in the American Medical Association increased by 5,601 during the year ending June 30, 1958, as compared with the same period ending June 30, 1957. A breakdown of the membership records as of June 30 indicates the following:

Reported Through Constituent Societies	*1958*	*1957*
Active Paid Members	136,062	133,034
Active Members Exempt from dues	10,344	10,216
Associate Members	6,293	6,127
Reported Direct		
Service Members	16,352	14,059
Affiliate Members	278	290
Honorary Members	89	91
Total Membership on June 30	169,418	163,817

The total income from 1958 membership dues for the first six months of 1958 was $3,337,622, which was an increase of $86,485 over the same period for 1957.

A new procedure was used to notify the apparently dues delinquent physicians that their eligibility for membership in the Association had not been established as of June 1, 1958. For the first time a reply card and an envelope addressed to the Executive Secretary of the physician's state or territorial medical society, was included with the delinquency notice. The reply card gave the physicians an opportunity to correct any misunderstanding that may have occurred regarding their continued A. M. A. membership. The new method was acclaimed by physicians and Executive Secretaries of the constituent associations and its use will be continued.

This year 10,066 physicians were notified that their membership for 1958 had not been established as of June 1; however, it was only necessary on June 30 to discontinue the membership of 3,379 physicians under the provisions of Chapter III, Section 5 of the A. M. A. Constitution and Bylaws.

The increase of 5,601 members was effected even though the names of 3,379 physicians were removed from the membership rolls on June 30, because their A. M. A. membership status for the year 1958 had not been established through their constituent medical association.

The following table shows the number of physician members of state and territorial medical societies who also hold membership in the American Medical Association. Comparative figures are given as of June 30 for both 1957 and 1958 (apportionment of delegates is based on the membership as recorded on December 31 of each year) (Bylaws, Chapter IX, Section 1 (C) (1)):

A. M. A. Membership on June 30

State	No. of Physicians in State on 12/31/57	Dues Paying	Dues Exempt	Associate Members	Total 1958	Total 1957
Alabama	2,367	1,538	298		1,836	1,770

Convention Registration Bureau

The Records and Circulation Department covers Registration activities in connection with both the Annual and Clinical Meetings of the American Medical Association, and is responsible for the proper registration and admittance of all member physicians and their guests.

The registration of the Philadelphia Clinical Meeting and the San Francisco Annual Meeting is shown in detail below.

Registration, Philadelphia, Dec. 3-6, 1957

Physicians	2,637
Residents	335
Interns	154
Students	747
Nurses	150
Technicians	56
Physicians' Guests	1,545
Total	5,624
Technical Exhibitors	936
Technical Exhibitors' Guests	340
Grand Total	6,900

Registration, San Francisco, June 23-27, 1958

Physicians	13,218
Residents	494
Interns	285
Students	419
Nurses	1,906
Technicians	626
Physicians' Guests	22,769
Total	39,717
Technical Exhibitors	2,528
Technical Exhibitors' Guests	1,310
Grand Total	43,555

Physicians' Biographical Records

Fiscal Year July 1, 1957 Through June 30, 1958

The complete Biographical records which are maintained for every licensed physician in the U. S. A. and Possessions, are now organized with the historical information manually recorded and a digest of the pertinent information maintained on IBM punched cards.

The information maintained in the Biographical Records is made available to all Councils, Bureaus and Departments of the American Medical Association as well as allied medical organizations. This information will be published, corrected to December 31, 1957, in the 20th (1958) Edition of the American Medical Directory.

Current changes and additions are made available to addressing firms and pharmaceutical houses through subscription to the semi-monthly Directory Report Service. This supplementary service is offered on a service-fee basis to authorized business firms, and brought the Association a revenue of $377,752.00 during the fiscal year.

During the fiscal year ending June 30, 8,995 physicians have been added to the Biographical Records, and approximately 25,100 changes of address have been recorded. 6,251 other changes not involving the address have also been recorded, and 4,187 physicians have been removed from the records because of death.

The Bureau of Medical Economic Research uses the information recorded in the IBM Punched Card Records for their statistical studies concerning the physician population. The Bureau of Investigation makes frequent use of the Biographical information in the historical records when verifying the identity of persons about whom various inquiries have been made.

The Biographical records are maintained for the benefit of the entire Association, and insofar as facilities are available, the information on the medical profession is made available to any individual or organization who has a legitimate request.

American Medical Directory Circulation

Fiscal Year July 1, 1957 Through June 30, 1958

Sale of the 19th (1956) Edition of the *American Medical Directory* has continued. A total of 17,248 copies have been distributed and only 33 copies of Volume 19 are still available.

The 20th (1958) Edition of the *American Medical Directory* has been printed, and will be bound and available for distribution this fall. During the current fiscal year, more than 8,000 advance subscription orders have been received.

This new Edition has entailed a considerable amount of editorial work, and has been printed from the IBM Statistical cards supplied by the Physicians' Biographical Record Branch.

Sale of the 20th Edition will continue through the next fiscal year.

IBM Service Branch

The Fiscal Year July 1, 1957, Through June 30, 1958

The Machine Records Systems Department was retitled the IBM Service Branch of the Records and Circulation Department this fiscal year. This realignment of responsibilities has enabled the IBM Service Branch to increase its activities and expand its service department functions.

Over 1,500,000 punched cards were processed by this branch in completing the conversion of the previously manually maintained Physicians' Biographical Statistical cards to a key-punched card system, which can now be processed mechanically. The physicians' index and all of the biographical sections of the 20th Edition (1958) *American Medical Directory* were produced from copy prepared from these punched cards.

The maintenance and processing of the Association's Membership Records required the processing of more than 500,000 punched cards for recording current membership records. The 1958 A. M. A. Membership Pocket Cards were prepared on IBM machines.

More than 75,000 punched cards were used to record the contributions to the American Medical Education Foundation, and the running of monthly, semi-annual and annual reports.

The Council on Medical Education and Hospitals made use of the IBM Service in preparing all listings and tables for the Directory of approved Internships and Residencies, as well as the statistical data for the Education and the State Board numbers of The Journal of the A. M. A.

In cooperation with the Bureau of Medical Economic Research, more than 500,000 punched cards have been prepared and tabulated for a special hospital study concerned with the in-patients discharged from the nation's hospitals during the week of October 21-27, 1956.

Under a contract with the U. S. Department of Health, Education and Welfare, more than 275,000 punched cards from the Physicians' Biographical Records were reproduced and used by the Civilian Defense Division.

Many other Councils, Bureaus and Departments made use of the IBM Services for special studies during the fiscal year, and future plans call for the expansion of such services.

Scientific Journals Circulation

From July 1, 1957, Through June 30, 1958

During the fiscal year ending June 30, 1958, the average net paid circulation of The Journal of the A. M. A. and the Nine Scientific Monthlies continued to show a gradual increase.

The average net paid weekly circulation for The Journal of the A. M. A. was 175,687. This was an increase of 1,100 paid copies per week over the previous fiscal year. The average total distribution for each weekly issue was 184,000.

A comparison of the average net paid monthly circulation for each of the Nine Scientific Monthlies during the last two fiscal years shows:

	7/1/57 to 6/30/58	7/1/56 to 6/30/57
A. M. A. Journal of Diseases of Children	*8,268*	*8,212*
A. M. A. Archives of Dermatology	*5,563*	*5,401*
A. M. A. Archives of Industrial Health	*3,433*	*3,236*
A. M. A. Archives of Internal Medicine	*10,522*	*10,310*
A. M. A. Archives of Neurology and Psychiatry	*5,636*	*5,564*
A. M. A. Archives of Ophthalmology	*7,621*	*7,497*
A. M. A. Archives of Otolaryngology	*5,867*	*5,810*
A. M. A. Archives of Pathology	*4,275*	*4,216*
A. M. A. Archives of Surgery	*8,854*	*8,357*

Two volumes of the *Quarterly Cumulative Index Medicus* were released during this fiscal year, and their net paid circulation was:

Q. C. I. M. Volume #57 (January to June, 1955)	4,497
Q. C. I. M. Volume #58 (July to December, 1955)	4,447

A comparison of the classification of subscribers who received the April 27, 1957, issue and the April 26, 1958, issue of The Journal of the A. M. A. follows:

Percentage of Total Net Paid Subscriptions

During the fiscal year ending June 30, 1958, the renewal percentage for each of the scientific periodicals continued at a high level. The average renewal percentage for each publication is indicated as follows:

	Renewal Average *July 1, 1957 through June 30, 1958, %*
Journal of the A. M. A.	78.3
A. M. A. Journal of Diseases of Children	91.2
A. M. A. Archives of Dermatology	99.6
A. M. A. Archives of Industrial Health	88.3
A. M. A. Archives of Internal Medicine	90.1
A. M. A. Archives of Neurology & Psychiatry	89.8
A. M. A. Archives of Ophthalmology	97.6
A. M. A. Archives of Otolaryngology	97.8
A. M. A. Archives of Pathology	94.3
A. M. A. Archives of Surgery	94.5
Quarterly Cumulative Index Medicus	98.3

The practice of including subscription order forms in various issues has been continued, and a number of subscriptions for the various publications have been received as a result of these insertions. A series of successful advertisements for subscriptions was placed in *The New Physician*, the official publication of *The Student* A. M. A. Similar advertisements have been scheduled in the subscription catalogues of the world's leading magazine agencies. This series of advertisements will be continued during the next fiscal year.

Sample copies, promotion circulars and subscription order forms for the scientific publications were distributed to physicians, dentists, and medical and professional personnel at the following meetings:

1. American Academy of General Practice
2. American College of Surgeons
3. American Dental Association
4. American Library Association
5. American Hospital Association
6. American Nurses Association
7. American Orthopsychiatric Association
8. American Public Health Association
9. Annual American Medical Association
10. Clinical American Medical Association
11. Student American Medical Association

Today's Health Circulation

The Fiscal Year July 1, 1957, through June 30, 1958

During this fiscal year, the Circulation of *Today's Health* reached its highest point since the founding of the Magazine as *Hygeia* in April, 1923. The average net paid circulation was 409,099 per month. The average total monthly distribution of copies during this period was 427,838.

A comparison of the classification of subscribers who received the May, 1957 and May, 1958 issue follows:

Percentage of Total Paid Subscriptions

Subscriber Classifications	May, 1958, %	May, 1957, %
Women	43.7	43.0
Men	24.3	23.1
M.D.	13.7	16.2
Teachers, Schools, Colleges	5.9	6.5
D.D.S.	2.8	3.0

Clubs, Y. M. C. A., Y. W. C. A.	0.1	0.1
Newsstand Sales	1.2	0.1
Bulk and Single Copy Sales	0.8	0.8
Net Paid Circulation	**471,988**	**400,062**

A portion of the circulation to physicians' and dentists' reception rooms was the result of the annual subscription project conducted by the Woman's Auxiliary to the American Medical Association. The *Today's Health* Subscription project theme for the National Auxiliary was "Increased Reception Room Readership". Local and State Medical Society Auxiliaries produced orders for 56,525 subscription years during this period. Presidents of State Auxiliaries who exceeded 100% of their subscription quota and the National Auxiliary Officers were honored at a luncheon in the Fairmont Hotel during the San Francisco Annual Meeting.

The practice of including order forms in each issue was continued and a large number of subscriptions have been received from prospects who saw the magazine in a reception room, school or library. Many new subscribers state that they subscribed to the magazine for the first time after seeing it in their Doctor's waiting room.

The magazine continues to have a healthy growth of circulation in all areas of the country, and the new editorial policies have helped raise the renewal percentage to approximately 52%. This compares favorably with nationally circulated consumer magazines who expect to approach a renewal of only 40%.

The present plans call for an average net paid circulation for the next fiscal year of approximately 440,000. This average net paid circulation, with a total distribution per month of 450,000, can be maintained with the aid of magazine agencies, the Medical Society Auxiliaries, and a substantial direct mail promotion campaign.

A comparison of the classification of subscribers who received the May, 1957, and May, 1958, issues of the A. M. A. *Archives of Internal Medicine* follows:

Percentage of Total Net Paid Subscriptions

Subscriber Classifications	May, 1958, %	May, 1957, %

Net Paid Circulation	**471,988**	**400,062**

A portion of the circulation to physicians' and dentists' reception rooms was the result of the annual subscription project conducted by the Woman's Auxiliary to the American Medical Association. The *Today's Health* Subscription project theme for the National Auxiliary was "Increased Reception Room Readership". Local and State Medical Society Auxiliaries produced orders for 56,525 subscription years during this period. Presidents of State Auxiliaries who exceeded 100% of their subscription quota and the National Auxiliary Officers were honored at a luncheon in the Fairmont Hotel during the San Francisco Annual Meeting.

The practice of including order forms in each issue was continued and a large number of subscriptions have been received from prospects who saw the magazine in a reception room, school or library. Many new subscribers state that they subscribed to the magazine for the first time after seeing it in their Doctor's waiting room.

The magazine continues to have a healthy growth of circulation in all areas of the country, and the new editorial policies have helped raise the renewal percentage to approximately 52%. This compares favorably with nationally circulated consumer magazines who expect to approach a renewal of only 40%.

The present plans call for an average net paid circulation for the next fiscal year of approximately 440,000. This average net paid circulation, with a total distribution per month of 450,000, can be maintained with the aid of magazine agencies, the Medical Society Auxiliaries, and a substantial direct mail promotion campaign.

Today's Health Circulation, July 1957 thru June, 1958

Month	Mail subscribers (individual)	News-dealers	Single copies	Bulk copies	Total net paid	Exchange & executive	Advertisers	Agents	Samples	Total distribution
July	374,859	211	465	159	375,694	720	1,535	2,019	12,580	392,548
August	392,837	233	95	113	393,278	829	1,544	2,034	4,735	402,420

June	425,395	5,500	1,076	1,323	433,294	845	2,356	2,873	33,861	473,229
Totals	4,839,428	27,549	7,316	34,896	4,909,189	9,875	22,180	27,729	165,081	5,134,054
Average Per Month	403,286	2,296	610	2,908	409,099	823	1,848	2,311	13,757	427,838

Over 32,000 teachers and schools regularly subscribe to the magazine, and since each copy received by a student or teacher will normally be read by more than one student, the actual High School, College and University readership is quite considerable.

Today's Health was displayed at 12 National Conventions this past fiscal year, where sample copies and promotion material were distributed to professional and health education leaders and allied medical personnel.

1. American Academy of General Practice
2. American College of Surgeons
3. American Dental Association
4. American Hospital Association
5. American Nurses Association
6. American Public Health Association
7. American Association for Health, Physical Education and Recreation
8. Annual American Medical Association
9. Clinical American Medical Association
10. National Catholic Education Association
11. National Education Association
12. Student American Medical Association

Steps were taken this year to test the sale of *Today's Health* on newsstands in all cities over 10,000 population. In October, approximately 8,000 copies of *Today's Health* were placed on sale through a national distributor.

This monthly distribution has increased to its present level of approximately 11,000 copies per month. Preliminary reports show that the monthly sales have ranged from 25% to 52%, and reports from the dealers indicate that the new cover and editorial approach for the magazine are the main contributing factors for the hope for future increased sales. Attached is a breakdown of the distribution of copies for the fiscal year ending June 30, 1958.

JUDICIAL COUNCIL

The Judicial Council has had four sessions during the past year during which it considered questions concerning ethical interpretations and matters relating to membership. It heard one appeal from a constituent association involving the right of a doctor to obtain membership in a component medical society. No evidence was presented at any stage of the proceedings to indicate that the constitution and bylaws of the component and constituent societies were not observed. The decision of the constituent association affirming the action of the component society was approved.

Since making its last annual report to the House of Delegates the Council has realized an ambition of long standing: the collection and distribution of representative opinions and interpretations of the Principles of Medical Ethics. For the first time in the Association's history members now have a collection of precedents to which they may turn when it becomes necessary to evaluate the ethical propriety of particular conduct.

The Council appreciates full well that basic ethical concepts do not change. It appreciates also that interpretations of ethical concepts may change with increased knowledge and fuller understanding. Consequently, the Council welcomes comments, suggestions and constructive criticism of its interpretations of the Principles of Medical Ethics.

The preferable method of bringing matters to the Council for consideration is, of course, through the constituent association. Unique or novel questions (which do not involve an actual controversy, and which do not place the Council in the position of prejudging a controversial matter pending at the local level) may be considered whether presented by an individual, a county society or a state association.

From time immemorial the Council has pointed out that the component society is an autonomous group and that as such one of its principal duties is to apply ethical principles. Apparently this obligation is not recognized clearly by the majority of component societies or is, at best, not accepted as a principal obligation. The Judicial Council, although it wishes to be helpful, has neither jurisdiction nor facilities to investigate and adjudicate the propriety of the ethical conduct or practices of members of component societies. With the "Opinions and Reports" now in general distribution and available as a guide it is hoped component societies will more readily assume their responsibility in this regard.

Illustrative of the type of problem which can and should be resolved locally is the following example: A physician sent a proposed contract directly to the Judicial Council for evaluation. Under the terms of this proposed contract a druggist offered to rent to the physician space in a building he owned and where his drugstore was located. The rent would be $1000 a month if the druggist filled none of the doctor's prescriptions. But if the physician sent the druggist an average of 10 prescriptions a day, the rent would be $900 a month; if he sent the druggist an average of 20 prescriptions a day, rent would be $800 a month. With each daily increase of ten prescriptions by the physician, the druggist agreed to reduce the monthly rental by $100 until the rental would be $1 a month if the physician sent the druggist an average of 100 prescriptions a day.

Clearly an individual physician or a county medical society should have recognized at once that no physician could ethically enter into such an arrangement which was clearly a secret rebate or a commission for referral of prescription business (See *J. A. M. A.* Special Edition, June 7, 1958, pages 40-41).

The Council has noted a failure on the part of physicians to turn to their county medical societies for information concerning the application of ethical principles and the failure of county societies to be more aggressive in developing a sound program of ethics. During recent months the Council's correspondence contained numerous letters from hospital administrators which commence with a statement similar to this: "One of the doctors on the staff of our hospital is in doubt concerning an ethical problem. He asked me what ethical rule governed. Will you please advise me so I can tell the doctor what his conduct should be."

Obviously a number of criticisms can be made of such a situation. Why should a doctor go to a hospital administrator with a question of ethics? Why should a hospital administrator accept responsibility for framing the doctor's question and seeking an answer to it? How often do hospital personnel, untrained in the history, tradition and total background of medical ethics, resolve or attempt to resolve questions of ethics? If this practice exists to any widespread degree what assurance is there of uniformity of opinion? What control is there of such practice to prevent expediency from influencing the answer which is given?

The Council has emphasized the autonomy of the county society and the fact that such autonomy imposes responsibility. If medical societies fail to accept and discharge their obligations in matters of ethics others will assume these obligations by default. The Judicial Council urges county and state societies to adopt critical attitudes toward their programs to "uphold the honor and dignity" of the profession of medicine. These programs must be based on a sound knowledge and understanding of ethical principles. As long as ethical principles are widely and sedulously observed the reputation of the medical profession will be upheld. The reward will be commensurate with the service rendered in observance of these ideals. On the other hand, if there is flagrant, open, or even careless disregard of ethical principles the reputation of the profession of medicine will suffer and its responsibilities and obligations will be usurped by others.

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The Council on Medical Education and Hospitals submits the following report covering the period from July 1, 1957, to June 30, 1958.

During the past year the Council has concerned itself with the various matters referred to it by the House of Delegates and in the pursuit of its multiple established activities. The latter include the survey and evaluation of medical schools; survey and evaluation of graduate medical education as conducted through internships, residencies, and fellowships; the collection and compilation of information on and listing of postgraduate opportunities in medical education; and the compilation of data concerning the education and training opportunities in certain technical areas related to medicine. In the course of conducting these functions, the Council and its staff have endeavored to contribute to and stimulate study and progress in medical education at all levels. These activities have necessitated consultations, conferences, collaboration, liaison, and intercommunication with many individuals and groups representing medical schools, hospitals, governmental and nongovernmental agencies, and other organizations, and institutions interested in and concerned with medical education in some or all of its aspects. The accreditation of basic medical education, graduate medical education and training, the collection, compilation, and dissemination of statistical and other information concerning medical schools, internships, residencies, postgraduate and continuation courses, medical licensure and related matters have been conducted in accord with established custom and modified in line with current needs.

Matters Referred to the Council by the House of Delegates

In December, 1957, the House of Delegates adopted Sections 2, 3, and 4 of Resolution 22 on the Distribution of Interns and referred them to the Council on Medical Education and Hospitals for referral to the Committee on Preparation for General Practice. The latter Committee has held numerous meetings during the course of the past year and a half during which the intern matters dealt with in Resolution 22 have been considered along with many other aspects of preparation for general practice. The Committee on Preparation for General Practice composed of representatives from the Council on Medical Education and Hospitals of the American Medical Association, the American Academy of General Practice, and the Association of American Medical Colleges submitted a report of progress to each of their parent organizations during May, 1958. The report was received by the Board of Trustees of the American Medical Association and presented to the House of Delegates at the June, 1958, meeting in San Francisco, as Supplementary Report A.

One of the major reasons for presenting this progress report was to advise the profession of the thinking of the Committee in regard to background preparation for general practice in the current setting and to elicit expressions of opinion and suggestions from the House of Delegates which might be of value in formulating the final report. The Reference Committee on Medical Education and Hospitals, after considering the report, recommended "that full consideration of this preliminary report be given by all members of the House of Delegates and that comments or suggestions be submitted to the Committee as suggested." The Committee on Preparation for General Practice will continue its meetings and anticipates a final definitive report as soon as possible. Further solution to Sections 2, 3, and 4 of Resolution 22 (December, 1957) should be possible when the final report is submitted as it will deal extensively with education beyond graduation from medical school.

Resolutions 26 and 27 dealing with the "Two Year Rotating Internship in Community and Municipal Hospitals," and "Plans to Promote Improved Intern Education and to Correct the Shortage of Interns," were introduced during the June, 1958, session of the House of Delegates. The Reference Committee on Medical Education and Hospitals referred these Resolutions to the Council on Medical Education and Hospitals for study and necessary action because of the continuing study it is carrying on with respect to the internship. The Council has continued to favor a sound well planned rotating internship as highly desirable. Furthermore, the Council in its annual compilation of internships lists many municipal and community hospitals as well as the major teaching hospitals which have been approved for such education and training experiences. The most recent edition of the "Essentials of an Approved Internship" states: "It is the opinion of the Council that the best general, basic education is provided by a well organized and conducted rotating internship."

The questions raised by Resolution 27 involve resolution of numerous problems such as length of time of deferment after graduation which will be allowed by Selective Service and the Military Services, whether or not specialty boards will give credit beyond a single year in a rotating internship unless the second year is specifically in the field of the specialty in which instance it is essentially a first year residency and not an internship. These constitute some of the problems currently confronting the Committee on Preparation for General Practice and the Council is grateful that the Reference Committee recognized this in its recommendations.

The Council has continued to study and implement the "One-Fourth Rule" in regard to internships which was adopted by the House of Delegates in June, 1955. The "One-Fourth Rule" stipulates that: "A hospital which for two consecutive years does not obtain one-fourth of its stated complement of interns may be disapproved for intern training." Communications concerning the interpretation of the ruling were sent to each hospital approved by the Council for intern training. Subsequently, based on information furnished by each hospital, the Council staff wrote letters of warning to each hospital which did not report at least one-fourth of its intern quota on duty Sept. 1, 1956. It was clearly indicated that failure to have at least one-fourth of its quota (the quota in each instance is established by the institution itself, except for Pennsylvania where the State Board sets intern quotas) for a second year would place its approved internship in jeopardy. In December, 1957, reports on internships were reviewed by the Council Staff to determine which institutions had been unable to fill one-fourth of their self-established quota for a second consecutive year. In February, 1958, 17 hospitals not having one-fourth of their intern quota for two consecutive years were presented to the Council for action. The Council directed that a final letter concerning the situation be sent to each hospital. All of these communications were sent by registered mail. In June, 1958, these 17 institutions were considered by the Internship Review Committee for recommendations to the Council and the following actions taken:

(a) Hospitals filling more than ¼ of their quota for July 1, 1958; continued approval	3 hospitals
(b) Hospitals having no interns for July 1, 1958; withdrawal of approval	9 hospitals (46 internships)
(c) Hospitals voluntarily requesting discontinuation of approval	2 hospitals (20 internships)
(d) Hospitals having ¼ of quota for July 1, 1958 and having potential for good intern training	3 hospitals

Thus in the first definitive action involving the one-fourth ruling, 11 hospitals offering 66 internships had their internship approval withdrawn.

Resolution 54 introduced at the June 1958 meeting of the House of Delegates resolved: "that the American Medical Association stimulate suitable legislation on a national level so that physicians and surgeons, licensed by examinations in Illinois, qualify for licensure in all states which recognize the principles of reciprocity." The Reference Committee on Medical Education and Hospitals recommended and the House of Delegates adopted a substitute resolution: "That the Board of Trustees of the American Medical Association be directed to take appropriate steps for the consummation of a study of the problems pertaining to licensure by reciprocity, and that it consult with the Federation of State Medical Boards in an attempt to find a satisfactory solution to this problem." This action was referred to the Council for action and report to the House. The resolution has subsequently been brought to the attention of the officers of the Federation of State Medical Boards for their consideration.

In regard to Resolution 55, introduced at the June, 1958, meeting, concerning Compulsory Assessments and Credits by Hospital Boards of Trustees, the Council wishes to report that copies of a similar resolution (Resolution 59, June, 1957) were mailed to the American Hospital Association, the Catholic Hospital Association, and the Protestant Hospital Association over a year ago and that both Resoltuion 59 (1957) and Resolution 55 (1958) are being brought to the attention of hospital boards, whenever this problem is presented.

Resolution 10 introduced at the June 1958 meeting requested "that the House of Delegates of the American Medical Association take appropriate measures to investigate the feasibility of the use of senior medical students in clinical clerkships in the place of first year interns in university hospitals." The reference committee recommended and the House of Delegates adopted this resolution which has subsequently been transmitted to the Association of American Medical Colleges for their consideration and comment.

Cooperation in Medical Education

In 1942 after consultation with and approval by the Board of Trustees, the Council developed an official working relationship with the Association of American Medical Colleges, the official organization of the medical schools, through the establishment of a Liaison Committee on Medical Education. Through this arrangement, it has been possible to share responsibilities, problems, challenges, and viewpoints in the many areas where the Council and the Association of American Medical Colleges have mutual concern and similar objectives.

The effectiveness and productiveness of this liaison has resulted in the development of somewhat similar working relationships with appropriate organizations in other fields of concern to the Council. Our responsibilities and objectives in graduate medical education and specialty training clearly overlap with those of the Advisory Board for Medical Specialties and with the individual specialty boards. This field of mutual endeavor now has formal expression through a Liaison Committee with the Advisory Board and through the various residency review committees. Similarly, the Internship Review Committee was formed to give other organizations that have a legitimate stake in the internship (e.g., the American Academy of General Practice, the Association of American Medical Colleges, American Hospital Association, Federation of State Boards) an opportunity to share viewpoints and efforts in this part of the Council's activities.

There are many other effective working partnerships now in existence and at the present time, with the concurrence of the Board of Trustees, planning is underway to establish a liaison committee consisting of representatives of our Board, the Council on Medical Education and Hospitals, University Presidents, and the Association of American Medical Colleges. It is believed that this holds great promise for future better understanding and relationships between organized medicine and its agent in medical education, the Council on Medical Education and Hospitals, and universities, who are ultimately responsible for the conduct of medical schools, and the Association of American Medical Colleges, which can be considered as the universities' agent in medical education.

The Council is of the sincere belief, based now on many years of direct experience, that this approach of cooperation and collaboration has worked to the distinct benefit of the Council's major objective as charged by the House of

Delegates many years ago to "make suggestions as to the means and methods by which the American Medical Association may best influence favorably medical education" and to "act as the agent of the American Medical Association (under instructions from the House of Delegates) in its efforts to elevate medical education."

Collaboration with the Association of American Medical Colleges

In cooperation with the Association of American Medical Colleges, the Council on Medical Education and Hospitals has prepared a number of important basic documents dealing with matters of concern in medical education. The former "Essentials of an Acceptable Medical School" prepared by the Council and authorized for publication by the House of Delegates of the American Medical Association has been replaced by "Functions and Structures of a Modern Medical School," representing the combined efforts of both groups. It was approved by the House of Delegates of the American Medical Association in June, 1957, by the Association of American Medical Colleges in October, 1957, and published in the late fall of 1957.

In view of the current interest in the potential development of additional two year basic medical science programs in institutions where such developments have promise, the Council on Medical Education and Hospitals (A. M. A.) and the Association of American Medical Colleges have developed a document on the "Functions and Structure of a Modern School of Basic Medical Sciences." This has been approved by the two Councils and by the Liaison Committee on Medical Education and will be presented and recommended for adoption by the two parent organizations at their next meeting (AAMC, October, 1958; A. M. A., November, 1958). This document will serve as a general guide in establishing and developing such two years programs. It is attached as Appendix A, and the Council seeks approval to use this statement as official policy in the future.

The Association of American Medical Colleges, the Council on Medical Education and Hospitals (A. M. A.) and the Liaison Committee representing the two groups have gone on record as favoring the establishment of two year basic medical science programs wherever the environmental situation is favorable. They have also gone on record as believing there is definite need for the development of additional four year medical schools in keeping with the demands resulting from increasing populations, trends in social and economic characteristics, and the changing dimensions of medical knowledge. Both groups have been contronted with numerous requests to evaluate communities or institutions as possible sites for the development of suitable medical education programs. The two Councils and the Liaison Committee, after giving much thought and study to this matter, have formulated certain basic concepts as to the circumstances under which they will undertake such cooperative studies. These concepts are directed toward initial clarification of the background of the requests and emphasize that the role of the liaison evaluation is not to determine whether any given state or area has need for more facilities for medical education, but to determine whether in a given setting there are sound and logical potentials for the development of either a two year basic medical science program or a four year medical school.

On June 1, 1958, the Council on Medical Education and Hospitals (A. M. A.) and the Executive Council of the Association of American Medical Colleges authorized and published a statement on "The Present and Future Status of Foreign Medical School Credentials in the United States." This statement includes informative data on the Educational Council for Foreign Medical Graduates, the present and future status of the list of foreign medical schools, the present and future status of graduates of foreign medical schools seeking internship and residency training in the United States under the Exchange-Visitor Program, and those entering the United States on permanent (immigration) visas. It also includes information on the status of American citizens studying medicine outside the United States and Canada, the policy of the American Hospital Association concerning graduates of foreign medical schools, and the policy of the National Intern Matching program in regard to such individuals.

For many years the Council on Medical Education and Hospitals has sent out an annual questionnaire to each medical school in the United States and Canada for information on which the data in the Educational Number of THE JOURNAL have been based. In order to overcome needless duplications and to obtain identical and more comprehensive information for the Council on Medical Education and Hospitals and for the Association of American Medical Colleges, this year the annual questionnaire has been developed as a collaborative effort.

In these and many other areas there has been excellent liaison between the American Medical Association and the Association of American Medical Colleges. The "top level" liaison mechanism which has been approved by the Board of Trustees and which will include representation from University presidents and the Association of American Medical Colleges, on the one hand, and the Board of Trustees of the American Medical Association and the Council on Medical Education and Hospitals, on the other hand, holds great promise in the future for the discussion of problems of mutual concern. It should result in minimizing areas of difficulty and misunderstanding such as have been precipitated during recent years by the changing character of medical practice, the changing status of the patient, and the changing character of the faculties of medical schools.

Medical School Studies and Accreditation

One of the important liaison functions of the Council on Medical Education and Hospitals with the Association of American Medical Colleges resides in the continuing study of medical schools in the United States and Canada.

In liaison with the Association of American Medical Colleges and for visits to Canadian medical schools in liaison also with the Association of Canadian Medical Colleges, the following institutions were surveyed by representatives of the Council on Medical Education and Hospitals during the academic year 1957-1958:

University of Kentucky School of Medicine
Dalhousie University Faculty of Medicine
Dartmouth Medical School
University of Manitoba Faculty of Medicine
Johns Hopkins University School of Medicine
University of Pittsburgh School of Medicine
College of Medical Evangelists
Woman's Medical College of Pennsylvania
Seton Hall College of Medicine
Albert Einstein College of Medicine of Yeshiva University
Georgetown University School of Medicine
University of Chicago School of Medicine
University of Florida College of Medicine
University of Arkansas School of Medicine
University of Michigan Medical School

The medical schools of Seton Hall and the University of Florida had the second year of their developing programs underway and both were granted provisional approval for these two years. Albert Einstein College of Medicine had the third year of its program in effect and will be eligible for consideration for full apprroval during the forthcoming academic year. The former two medical schools (Seton Hall and University of Florida) will be similarly eligible in the academic year 1960-1961.

The visit to the University of Kentucky was at the request of university officials to consult with them regarding the development of their final plans for the medical school. It is expected that the first medical class will be enrolled for the 1960-1961 academic year.

The schedule for liaison survey visits for the coming academic year (1958-1959) includes the following institutions:

University of Ottawa Faculty of Medicine
Jefferson Medical College
Yale University School of Medicine
Bowman Gray School of Medicine of Wake Forest College
University of Colorado School of Medicine
Columbia University College of Physicians and Surgeons
Stritch School of Medicine of Loyola University
Albert Einstein College of Medicine of Yeshiva University
University of Kansas School of Medicine
Washington University School of Medicine
Creighton University School of Medicine

Potential Sites for New Medical Schools

During the year covered by this report, committees composed of representatives of the Council on Medical Education and Hospitals and the Association of American Medical Colleges, on invitation of all pertinent agencies, visited San Antonio and Austin in Texas to determine whether these sites appeared to offer a suitable location for the development of a third state owned medical school in Texas. It was concluded that both sites offer a favorable environment for the location of a medical school.

Annual Report on Medical Education in the United States and Canada

One of the original charges given to the Council on Medical Education and Hospitals under which the Council still functions is: "To make an annual report to the House of Delegates on the existing conditions of medical education in the United States." This responsibility is discharged through the annual publication of a comprehensive report in The Journal. The report covering 1956-57 was presented in volume 165, pages 1393-1460 of the Nov. 16, 1957, issue of The Journal and reprints were subsequently directed to members of the House of Delegates. The report covering 1957-1958 will be presented in the Nov. 15, 1958, issue of The Journal and the Council respectfully directs the attention of the House to it. Reprints of the report will be transmitted to members of the House of Delegates as soon as they become available.

Annual Congress on Medical Education and Licensure

The 54th Annual Congress on Medical Education and Licensure was held Feb. 8-11, 1958, in Chicago. The Council is pleased to inform the House of Delegates that again a new attendance record of 997 formal registrants was attained.

A major effort of the 54th Congress was to focus attention on future needs in medical education in relationship not only to the changing dimensions of medical knowledge but also to population trends, the changing characteristics of society, and the changing characteristic of our economy. Emphasis was placed on an attempt to identify in these areas those questions to which answers should be found, in order that future planning in medical education can be placed on as sound basis as possible.

This part of the Congress had more than fifty active participants. In addition to individuals knowledgeable in medical education and practice (Officers and all members of the Board of Trustees played active roles), the participants included respected representatives of higher education, industry, insurance, economics, sociology, demography, labor, agriculture, government, and hospital administration. In a very real sense, it can be said that the producers, distributors, and consumers of medical service all had a voice in these discussions. Attention is now being given to the feasibility of initiating a study directed toward seeking answers to the many important questions which were formulated.

A half day of the Congress was devoted to a consideration of problems in specialty training resulting from the changing status of patients, most particularly that related to the impact of medical care insurance in greatly reducing the numbers of ward service patients. This part of the program was co-sponsored by the Advisory Board for Medical Specialties and distinguished speakers presented the problems and suggested means of overcoming them in each of the major clinical disciplines.

The remainder of the Congress was devoted to activities of the Federation of State Medical Boards of the United States. Its second Examination Institute dealt with Anatomy, Pathology, Surgery, and Bacteriology. The problem of the physician as a drug addict was the subject of the Federation's regular Tuesday morning session.

The papers presented during the Council's program have been published in the May 3 and May 10, 1958, issues of The Journal and collected tear sheet copies have been forwarded to all members of the House of Delegates. The Council is of the opinion that these papers contain a great deal of information of importance in the current setting and respectfully directs the attention of the members of the House of Delegates to them.

The 55th Congress on Medical Education and Licensure scheduled for February 1959 will focus attention on two areas of serious concern in their relation to Medical Education. Specialism and research are both crucial factors in medical education and practice, and promise to play even greater roles in the future. They present tremendous challenges and opportunities but demand careful study and reappraisal, in so far as determining their logical inter-relationship with both medical education and practice.

The Educational Council for Foreign Medical Graduates

This organization is now in active operation and conducted its first complete evaluation of graduates of foreign medical schools in March, 1958. Another examination will be given both in the United States and in 32 testing centers throughout the world in September, 1958. Thereafter it is planned to hold examinations both in the United States and abroad twice each year.

In keeping with policy sanctioned by the House of Delegates when the final report of the Cooperating Committee on Foreign Medical Graduates was approved in June, 1956, the Council (in collaboration with the Association of American Medical Colleges) has announced the withdrawal of the listing of certain foreign medical schools to be effective Jan. 1, 1960. In place of the recommendation that graduates of foreign medical schools on the list be considered on a basis comparable to graduates of our own approved medical schools, after Jan. 1, 1960, the Council recommends that graduates of foreign medical schools who have been successfully certified by the Educational Council for Foreign Medical Graduates be considered on a basis comparable to graduates of our own approved schools.

The Council staff continues to assist this new organization in every manner possible and rather regularly is asked to meet with the Educational Council's Board of Trustees. Although a further period of time will be necessary for the Educational Council to have its full impact, already many specialty boards and licensing boards are taking advantage of this new program.

Committee Activities of the Council

The committee activities of the Council on Medical Education and Hospitals are numerous and demanding of much time and effort on the part of both Council and staff personnel. Such activities are kept to a minimum consistent with conducting the studies and responsibilities connected with the Council's duly designated functions or special assignments.

Standing Committees

Standing Committees include:

Committee on Essentials which is responsible for review, revision, and recommendations regarding the "Essentials" and "Guides" underlying the various education and training programs approved or accredited by the Council.

Liaison Committee on Medical Education which consists of representation from the Council on Medical Education and Hospitals and the Executive Council of the Association of American Medical Colleges. This Liaison Committee serves a very important function in intercommunication and cooperation between the two parent organizations.

Liaison Committee with the Advisory Board for Medical Specialties which is concerned with matters of mutual interest to the Council and the Advisory Board and which collaborates in planning for the Annual Congress on Medical Education and Licensure.

Residency Review and Conference Committees. The "Background and Development of Residency Review and Conference Committees" is described in detail in a resume prepared by the staff of the Council and published in the September 7, 1957, issue of THE JOURNAL. These committees include representatives of the specialty boards concerned and in certain instances representation from the American College of Physicians or the American College of Surgeons in addition to Council representation. The American Academy of Pediatrics has recently been added to make pediatrics a tripartite committee. These committees meet from one to three times annually to review and take action concerning the approval of graduate education and training programs in their respective fields. These committees have also in certain instances prepared "Guides" to assist individuals and institutions in planning and developing graduate education and training programs as well as aiding field staff personnel in determining those aspects of the program which require special evaluation. Notable among these guides which have been prepared during the past year is the Guide Book for Residency Programs in General Surgery approved by the American Board of Surgery, the American College of Surgeons and the Council, and the three "Guides" for residencies in Aviation Medicine, Occupational Medicine, and Public Health, formulated by the Residency Review Committee for Preventive Medicine and approved by the American Board of Preventive Medicine and the Council.

Council staff personnel function as secretaries of each of the committees and conduct their administrative activities. With the development of a tripartite Residency Review Committee in Obstetrics and Gynecology (Council on Medical Education and Hospitals, American Board of Obstetrics and Gynecology, and American College of Surgeons) there are now 17 active Residency Review and/or Conference Committees, as listed:

Residency Review Committee for Anesthesiology
Residency Review Committee for Dermatology
Residency Review Committee in Internal Medicine (tripartite)
Residency Review Committee for Neurological Surgery
Residency Review Committee for Ophthalmology
Residency Review Committee for Orthopedic Surgery
Residency Review Committee for Otolaryngology (tripartite)
Residency Review Committee for Pediatrics (tripartite)
Residency Review Committee for Physical Medicine and Rehabilitation
Residency Review Committee for Plastic Surgery (tripartite)
Residency Review Committee for Preventive Medicine
Residency Review Committee for Proctology
Residency Review Committee for Psychiatry and Neurology
Residency Review Committee for Radiology
Conference Committee on Graduate Training in Surgery (tripartite)
Residency Review Committee for Urology
Residency Review Committee for Obstetrics and Gynecology (tripartite)

There is also a Residency Review Committee in General Practice on which there is liaison representation from the Council on Medical Education and Hospitals and the American Academy of General Practice.

An Internship Review Committee with representation from the Council, the American Academy of General Practice, the American Hospital Association, the Association of American Medical Colleges, and the Federation of State Medical Boards now reviews all new applications for internship approval or further extension of approval of existing programs and recommends action to the Council.

The Advisory Committee on Physical Therapy Education has multiple representation from groups interested in this field with Council staff personnel conducting its administrative functions.

The Advisory Committee on Occupational Therapy Education has multiple representation from groups interested in the field with Council staff again conducting its administrative functions.

The Committee on Licensure which is a standing committee has held no meetings during the past year.

Other Committees

The *Ad Hoc* Advisory Committee on Postgraduate Medical Education was invited to continue its studies following completion of its initial assignment. Its further activities are described in the section of this report entitled "Postgraduate Medical Education."

Members of the Council have been active participants in the Program Committee Planning the Second World Conference on Medical Education scheduled in Chicago in August 1959.

As indicated earlier in this report, the Council and its staff have been actively engaged in the cooperative Committee on Preparation for General Practice. An important Progress Report has been submitted and a final report should be developed in the near future.

Council and staff members have also participated actively as members or officials of numerous other committees and organizations concerned with problems closely related to or impinging upon the field of medical education, such as:

Joint Commission on Accreditation of Hospitals
National Intern Matching Programs
National Fund for Medical Education (Advisory Council)
American Medical Education Foundation
National Board of Medical Examiners
Federation of State Medical Boards of the United States (Bulletin)
Selective Service System
Education and Training Division, Surgeon General's Office Department of the Army
Education and Training Division, Surgeon General's Office, U. S. A. F.
Experimental Training Grants Committee, National Institutes of Health
National Conference on Public Health Training
Council on Professional Practice A. H. A. (Liaison)
Task Force on Health Manpower

Furthermore, the Council and its staff collaborate with many other organizations and agencies having an interest in one or more aspects of medical education. Such cooperation many entail participation in special committees, consultation or advising, etc. Intercommunication between the Council and these various groups or individuals constitutes one of the demanding functions in terms of time, energy, and basic significance from the standpoint of professional and public relations.

Graduate Medical Education

The Council is responsible for continuous study and concern in the maintenance of appropriate standards in medical education at the graduate level. It collaborates with the Advisory Board for Medical Specialties and with numerous other organizations, as noted in the subsequent sections in this report on the Internship and Residencies, through review committees which are liaison bodies for maintaining training standards in approved internship and residency educational programs. In addition to liaison with these organizations, the Council works closely with the National Intern Matching Plan, the Educational Council for Foreign Medical

The schedule for liaison survey visits for the coming academic year (1958-1959) includes the following institutions:

University of Ottawa Faculty of Medicine
Jefferson Medical College
Yale University School of Medicine
Bowman Gray School of Medicine of Wake Forest College
University of Colorado School of Medicine
Columbia University College of Physicians and Surgeons
Stritch School of Medicine of Loyola University
Albert Einstein College of Medicine of Yeshiva University
University of Kansas School of Medicine
Washington University School of Medicine
Creighton University School of Medicine

Potential Sites for New Medical Schools

During the year covered by this report, committees composed of representatives of the Council on Medical Education and Hospitals and the Association of American Medical Colleges, on invitation of all pertinent agencies, visited San Antonio and Austin in Texas to determine whether these sites appeared to offer a suitable location for the development of a third state owned medical school in Texas. It was concluded that both sites offer a favorable environment for the location of a medical school.

Annual Report on Medical Education in the United States and Canada

One of the original charges given to the Council on Medical Education and Hospitals under which the Council still functions is: "To make an annual report to the House of Delegates on the existing conditions of medical education in the United States." This responsibility is discharged through the annual publication of a comprehensive report in THE JOURNAL. The report covering 1956-57 was presented in volume 165, pages 1393-1460 of the Nov. 16, 1957, issue of THE JOURNAL and reprints were subsequently directed to members of the House of Delegates. The report covering 1957-1958 will be presented in the Nov. 15, 1958, issue of THE JOURNAL and the Council respectfully directs the attention of the House to it. Reprints of the report will be transmitted to members of the House of Delegates as soon as they become available.

Annual Congress on Medical Education and Licensure

The 54th Annual Congress on Medical Education and Licensure was held Feb. 8-11, 1958, in Chicago. The Council is pleased to inform the House of Delegates that again a new attendance record of 997 formal registrants was attained.

A major effort of the 54th Congress was to focus attention on future needs in medical education in relationship not only to the changing dimensions of medical knowledge but also to population trends, the changing characteristics of society, and the changing characteristic of our economy. Emphasis was placed on an attempt to identify in these areas those questions to which answers should be found, in order that future planning in medical education can be placed on as sound basis as possible.

This part of the Congress had more than fifty active participants. In addition to individuals knowledgeable in medical education and practice (Officers and all members of the Board of Trustees played active roles), the participants included respected representatives of higher education, industry, insurance, economics, sociology, demography, labor, agriculture, government, and hospital administration. In a very real sense, it can be said that the producers, distributors, and consumers of medical service all had a voice in these discussions. Attention is now being given to the feasibility of initiating a study directed toward seeking answers to the many important questions which were formulated.

A half day of the Congress was devoted to a consideration of problems in specialty training resulting from the changing status of patients, most particularly that related to the impact of medical care insurance in greatly reducing the numbers of ward service patients. This part of the program was co-sponsored by the Advisory Board for Medical Specialties and distinguished speakers presented the problems and suggested means of overcoming them in each o the major clinical disciplines.

The remainder of the Congress was devoted to activitie of the Federation of State Medical Boards of the Unite States. Its second Examination Institute dealt with Anatomy Pathology, Surgery, and Bacteriology. The problem of th physician as a drug addict was the subject of the Federation's regular Tuesday morning session.

The papers presented during the Council's program hav been published in the May 3 and May 10, 1958, issues o THE JOURNAL and collected tear sheet copies have been forwarded to all members of the House of Delegates. Th Council is of the opinion that these papers contain a grea deal of information of importance in the current setting an respectfully directs the attention of the members of th House of Delegates to them.

The 55th Congress on Medical Education and Licensur scheduled for February 1959 will focus attention on tw areas of serious concern in their relation to Medical Education. Specialism and research are both crucial factors i medical education and practice, and promise to play eve greater roles in the future. They present tremendous challenges and opportunities but demand careful study and reappraisal, in so far as determining their logical inter-relationship with both medical education and practice.

The Educational Council for Foreign Medical Graduates

This organization is now in active operation and conducted its first complete evaluation of graduates of foreig medical schools in March, 1958. Another examination wi be given both in the United States and in 32 testing center throughout the world in September, 1958. Thereafter it i planned to hold examinations both in the United States an abroad twice each year.

In keeping with policy sanctioned by the House of Delegates when the final report of the Cooperating Committe on Foreign Medical Graduates was approved in June, 195 the Council (in collaboration with the Association of American Medical Colleges) has announced the withdrawal the listing of certain foreign medical schools to be effectiv Jan. 1, 1960. In place of the recommendation that graduate of foreign medical schools on the list be considered on basis comparable to graduates of our own approved medica schools, after Jan. 1, 1960, the Council recommends th graduates of foreign medical schools who have been successfully certified by the Educational Council for Foreign Medical Graduates be considered on a basis comparable to graduates of our own approved schools.

The Council staff continues to assist this new organization in every manner possible and rather regularly is asked to meet with the Educational Council's Board of Trustees. Although a further period of time will be necessary for the Educational Council to have its full impact, already many specialty boards and licensing boards are taking advantage of this new program.

Committee Activities of the Council

The committee activities of the Council on Medical Education and Hospitals are numerous and demanding of much time and effort on the part of both Council and staff personnel. Such activities are kept to a minimum consistent with conducting the studies and responsibilities connected with the Council's duly designated functions or special assignments.

Standing Committees

Standing Committees include:

Committee on Essentials which is responsible for review, revision, and recommendations regarding the "Essentials" and "Guides" underlying the various education and training programs approved or accredited by the Council.

Liaison Committee on Medical Education which consists of representation from the Council on Medical Education and Hospitals and the Executive Council of the Association of American Medical Colleges. This Liaison Committee serves a very important function in intercommunication and cooperation between the two parent organizations.

Liaison Committee with the Advisory Board for Medical Specialties which is concerned with matters of mutual interest to the Council and the Advisory Board and which collaborates in planning for the Annual Congress on Medical Education and Licensure.

Residency Review and Conference Committees. The "Background and Development of Residency Review and Conference Committees" is described in detail in a resume prepared by the staff of the Council and published in the September 7, 1957, issue of THE JOURNAL. These committees *include representatives of the specialty boards concerned* and in certain instances representation from the American College of Physicians or the American College of Surgeons in addition to Council representation. The American Academy of Pediatrics has recently been added to make pediatrics a tripartite committee. These committees meet from one to three times annually to review and take action concerning the approval of graduate education and training programs in their respective fields. These committees have also in certain instances prepared "Guides" to assist individuals and institutions in planning and developing graduate education and training programs as well as aiding field staff personnel in determining those aspects of the program which require special evaluation. Notable among these guides which have been prepared during the past year is the Guide Book for Residency Programs in General Surgery approved by the American Board of Surgery, the American College of Surgeons and the Council, and the three "Guides" for residencies in Aviation Medicine, Occupational Medicine, and Public Health, formulated by the Residency Review Committee for Preventive Medicine and approved by the American Board of Preventive Medicine and the Council.

Council staff personnel function as secretaries of each of the committees and conduct their administrative activities. With the development of a tripartite Residency Review Committee in Obstetrics and Gynecology (Council on Medical Education and Hospitals, American Board of Obstetrics and Gynecology, and American College of Surgeons) there are now 17 active Residency Review and/or Conference Committees, as listed:

Residency Review Committee for Anesthesiology
Residency Review Committee for Dermatology
Residency Review [illegible]
Residency Review [illegible]
Residency Review Committee for Ophthalmology
Residency Review Committee for Orthopedic Surgery
Residency Review Committee for Otolaryngology (tripartite)
Residency Review Committee for Pediatrics (tripartite)
Residency Review Committee for Physical Medicine and Rehabilitation
Residency Review Committee for Plastic Surgery (tripartite)
Residency Review Committee for Preventive Medicine
Residency Review Committee for Proctology
Residency Review Committee for Psychiatry and Neurology
Residency Review Committee for Radiology
Conference Committee on Graduate Training in Surgery (tripartite)
Residency Review Committee for Urology
Residency Review Committee for Obstetrics and Gynecology (tripartite)

There is also a Residency Review Committee in General Practice on which there is liaison representation from the Council on Medical Education and Hospitals and the American Academy of General Practice.

An Internship Review Committee with representation from the Council, the American Academy of General Practice, the American Hospital Association, the Association of American Medical Colleges, and the Federation of State Medical Boards now reviews all new applications for internship approval or further extension of approval of existing programs and recommends action to the Council.

The Advisory Committee on Physical Therapy Education has multiple representation from groups interested in this field with Council staff personnel conducting its administrative functions.

The Advisory Committee on Occupational Therapy Education has multiple representation from groups interested in the field with Council staff again conducting its administrative functions.

The Committee on Licensure which is a standing committee has held no meetings during the past year.

Other Committees

The *Ad Hoc* Advisory Committee on Postgraduate Medical Education was invited to continue its studies following completion of its initial assignment. Its further activities are described in the section of this report entitled "Postgraduate Medical Education."

Members of the Council have been active participants in the Program Committee Planning the Second World Conference on Medical Education scheduled in Chicago in August 1959.

As indicated earlier in this report, the Council and its staff have been actively engaged in the cooperative Committee on Preparation for General Practice. An important Progress Report has been submitted and a final report should be developed in the near future.

Council and staff members have also participated actively as members or officials of numerous other committees and organizations concerned with problems closely related to or impinging upon the field of medical education, such as:

Joint Commission on Accreditation of Hospitals
National Intern Matching Programs
National Fund for Medical Education (Advisory Council)
American Medical Education Foundation
National Board of Medical Examiners
Federation of State Medical Boards of the United States (Bulletin)
Selective Service System
Education and Training Division, Surgeon General's Office Department of the Army
Education and Training Division, Surgeon General's Office, U. S. A. F.
Experimental Training Grants Committee, National Institutes of Health
National Conference on Public Health Training
Council on Professional Practice A. H. A. (Liaison)
Task Force on Health Manpower

Furthermore, the Council and its staff collaborate with many other organizations and agencies having an interest in one or more aspects of medical education. Such cooperation many entail participation in special committees, consultation or advising, etc. Intercommunication between the Council and these various groups or individuals constitutes one of the demanding functions in terms of time, energy, and basic significance from the standpoint of professional and public relations.

Graduate Medical Education

The Council is responsible for continuous study and concern in the maintenance of appropriate standards in medical education at the graduate level. It collaborates with the Advisory Board for Medical Specialties and with numerous other organizations, as noted in the subsequent sections in this report on the Internship and Residencies, through review committees which are liaison bodies for maintaining training standards in approved internship and residency educational programs. In addition to liaison with these organizations, the Council works closely with the National Intern Matching Plan, the Educational Council for Foreign Medical

Graduates, the educational services of the several federal agencies, and other organizations interested in and concerned with graduate medical education.

The Council compiles data on internship and residencies which are published each fall in THE JOURNAL as an Annual Report on Graduate Medical Education in the United States This report includes an up-to-date listing of all hospitals offering approved intern and/or resident training programs and the current requirements of examining boards in the medical specialties. The criteria used to evaluate educational programs are revised as necessary and are published as approved and authorized by the House of Delegates as "Essentials of an Approved Internship" and "Essentials of Approved Residencies and Fellowships." Other pamphlets concerning graduate medical education are published and revised as needed.

Hospital Survey Programs

Just as the examination and evaluation of basic medical school programs constitutes an important aspect of their accreditation, the examination and analysis of internships and residencies is an essential part of accreditation in graduate medical education and training.

Since January, 1957, the Council on Medical Education and Hospitals, by order of the House of Delegates, has restricted its hospital activities to the survey and evaluation of internships and residencies and their subsequent status. Currently there are six members of the field staff assigned to areas determined on the basis of the number of graduate programs to be evaluated. The current role of the Council in restriction of its activities in this manner has proven satisfactory to both the Council and the Joint Commission on Accreditation of Hospitals.

Field representatives are selected on the basis of their interest, knowledge, and experience in medical education, and on their ability to represent the Council with firmness, tact, and diplomacy. Their function is to act as consultants in regard to intern and resident training programs, aiding hospital administrators and medical staffs in analyzing and understanding their problems and assisting in the interpretation of the standards of graduate medical education. Although their observations and reports constitute important factors in the evaluation and actual accreditation of programs in graduate medical education, the Council does not consider its field staff as a policing group but rather as a consulting and advisory group.

Each field staff representative covers the graduate education and training programs in from 200 to 250 hospitals during an average year, and re-evaluates them at intervals of two to three years. Whenever it is feasible the field staff representatives are invited to sit with Residency Review or Conference Committees during their meetings at which time definitive action is taken regarding approval status.

The accompanying table presents a comparative analysis of the survey activities of the field staff during the past two years:

	1957	1958
Hospitals visited	793	915
Internships reviewed	288	421
Residencies reviewed	1,922	2,168
Total programs reviewed	2,210	2,589

The Council on Medical Education and Hospitals acknowledges with sincere appreciation the untiring efforts of its field representatives in their endeavors to assist in maintaining and improving the high standards of medical education at the intern and residency levels.

The Internship

The Internship Section of the Council is responsible for all activities in connection with the intern training programs in the United States, the Canal Zone, Hawaii, and Puerto Rico. Statistical and information material on internships are prepared in this section for publication in THE JOURNAL as part of The Annual Report on Graduate Education. All other activities regarding the various intern training programs, including correspondence, are handled in this section. The assistant secretary of the Council in charge of this section also acts as the secretary of the Internship Review Committee.

This section works closely with the National Intern Matching Program, collaborating with it in the correlation of its activities with the work on the Council in the internship field.

For the last intern training year (July 1, 1957, to June 30, 1958), there were 1,093 approved intern training programs approved by the Council. Offered in these programs were 12,325 internship positions. These were divided into 842 programs of the rotating type: 34 mixed programs; and 217 programs of straight services. The rotating services comprised 87.6% of the total; mixed 1.6%; and straight services 10.8%. These relative percentages have varied only slightly during the past several years.

Following clarification of the status of the straight internships by the House of Delegates in June, 1957, there has been an increase in the number of approved straight internship programs. Since June, 1957, the following actions have been taken regarding straight internships:

	New Approvals	Dis-approvals	Approval Withdrawn
Straight internships—			
Internal Medicine	4	1	2
Surgery	5	2	1
Pediatrics	5	—	1
Pathology	6	—	—
Obstetrics-gynecology	8	4	—
Totals	28	7	4

The large majority of straight internships are offered by hospitals affiliated with medical schools. Programs of straight internships have increased from 217 on Sept. 1, 1957, to 237 programs offered for the year beginning July 1, 1959. In view of the status of straight internships, as approved by the House of Delegates in June, 1957, this increase has been expected.

The Internship Review Committee and the Council have carefully reviewed each application for straight internship approval during the past year, and have found that approval of the programs indicated above was justified in every instance.

National Intern Matching Program

The National Intern Matching Program continues to serve as the central clearing agency for hospital seeking interns and for medical students desiring internships. For the past seven years, hospitals approved for intern training by the Council on Medical Education and Hospitals and medical students seeking internships have used the NIMP as the official agency for intern procurement. The plan gives complete freedom of choice to both hospitals and students and has received continued support from both groups.

Hospitals approved by the Council submit a Hospital Agreement to the Program in which they agree to interview only students who participate in the Program and to accept all interns matched to them. Students submit similar agreements, stating they will apply only to participating hospitals and will accept the hospital to which they are matched. Hospitals and students make contact with each other by means of the NIMP Directory. Hospitals receive a Directory of all participating students, and students receive a hospital Directory in which are listed all participating hospitals and the type and number of internships each offers. Hospitals are free to interview as many applicants as possible, using any means of evaluation they desire.

The Matching Program has matched more than 42,000 students with no reported error to date. The policies and general management of the program are governed by the organizations most interested in medical education at the intern level. These organizations include, in addition to the Council on Medical Education and Hospitals, the American Hospital Association, the Association of American Medical Colleges, the Catholic Hospital Association, the American Protestant Hospital Association, and the Student American Medical Association. Further assistance is given by liaison representatives from the Army, Navy, Air Force, and the Public Health Service.

The Program covers internships beginning between April 1 and Dec. 31. In Program VII for 1958 internships, 819 hospitals offered 11,958 positions, while 7,131 students participated in the program. Of this number, 6,734 (94%) were matched. Of the matched students, 88% went to hospitals of their first or second choice. Conversely, 89% of the hospitals received medical students whom they had selected as first or second choice.

All of the above figures include those graduates of foreign medical schools who participated in Program VII. Out of the 376 participating, 224 were matched. For Program VIII (the next matching), NIMP will require certification by the Educational Council for Foreign Medical Graduates. This will undoubtedly reduce the number of foreign graduates participating in the next matching.

Residencies

At the present time approval of programs for residency training may be granted in 28 areas. This includes programs in pediatric allergy, a category which is published for the first time in the 1958 Internship and Residency Number of The Journal. It also includes three preventive medicine specialties: aviation medicine, occupational medicine, and public health. Separate approval is offered in obstetrics and gynecology, or in a combined obstetrics-gynecology program. Likewise, approval is granted to separate or combined programs of psychiatry and neurology, and in pathologic anatomy and clinical pathology.

In the 1958 Internship and Residency Number of The Journal, no programs are listed in malignant disease since, after two years of notice to the hospitals concerned, such programs will not be approved after July 1, 1959.

The policy of requiring residency training programs to provide full training in a specialty—either intramurally or through affiliation with another program—has been adopted in a number of specialties. For some time, this policy has been in effect for programs in allergy, anesthesiology, cardiovascular disease, gastroenterology, orthopedic surgery, pediatrics, otolaryngology, plastic surgery, radiology, general surgery, and urology. During the past year, physical medicine and rehabilitation and proctology have been added to this group. Consideration is being given currently to adoption of this requirement in other specialty fields.

These policies have been adopted to preclude the possibility of a resident's taking his training in two or three isolated programs with no assurance of continuity of supervised experience or progression of responsibility. Hospitals which offer residencies in these specialties may offer periods of training of varied length; however, these residencies provide training as a part of a coordinated and integrated educational experience. The Council considers the principle of continuity in full training programs to be eminently sound and supports efforts directed toward this end.

On Sept. 1, 1958, 1,248 hospitals offered 5,299 approved residency training programs, involving 30,595 positions.

Revision of Essentials for Residency Training

Minor changes have been made in the Essentials for an Approved Residency in Anesthesiology, primarily for purposes of clarification. The section which reads as follows:

> "However, should a residency program consist of three years, one year of research if contained therein may be accredited as stated below.
>
> An exchange residency relationship between hospitals of equal caliber may be desired and acceptable."

was deleted and was replaced by the following statement:

> "Under current regulations, if a candidate elects to take additional training he may apply for approval of this training to the Secretary of the American Board of Anesthesiology, Inc."

The Council recommended approval of this minor editorial revision which is being referred for the information of the House of Delegates.

The Committee on Essentials noted certain discrepancies between the Essentials for Residencies in General Surgery and the Guide Book for Residency Programs in General Surgery which had been prepared by the Conference Committee on Graduate Training in Surgery. In order to bring these into complete agreement and to avoid possible misinterpretations, the Committee on Essentials recommended and the Council approved that the section in the Essentials of Residencies in General Surgery reading as follows be deleted:

> "It is desirable, and in most programs it is possible, to have the resident assigned for a period of service in the department of pathology."

This is replaced by the following statement:

> "Hospitals might wish to consider in four year residencies exclusive assignments of up to six months' duration to surgical pathology, and in three year residencies, part-time assignments to pathology."

This editorial revision eliminates the discrepancies referred to above and is referred to the House of Delegates for information.

In Neurological Surgery and Urology definite changes of meaning have been made in the Essentials and these changes are referred to the House of Delegates with the recommendation that they be approved.

For Neurological Surgery, the changes are as follows: Basically, these new Essentials follow the old ones with only minor revisions in wording, most of which are in the direction of brevity. The chief changes are to provide four years of training in accordance with the Board's new requirements for certification, and to omit the requirement of a straight internship in surgery. There are also changes in the quantitative requirements for approval. These new quantitative requirements of 200 major neurological procedures and 25 surgically verified intracranial tumors, although they have not been included in the Essentials, have as a practical manner, been the criteria by which the Residency Review Committee has judged programs.

For Urology the changes are of sufficient magnitude so that the complete revision is included in *Appendix B.* The Council has approved these revisions and recommends their adoption by the House of Delegates.

Postgraduate Medical Education

The *Ad Hoc* Advisory Committee on Postgraduate Medical Education, appointed in 1956 for the formulation of a program of action whereby the Council can provide the greatest assistance in the continuation education of physicians in practice, continued its studies in 1957 and 1958. It is still at work. The Committee consists of the following members:

Clarence E. de la Chapelle, M.D., Professor of Medicine and Associate Dean, New York University Post-Graduate School of Medicine, also a member of the Continuation Education Committee, Association of American Medical Colleges;

John Conlin, M.D., Director, Boston City Hospital, and previously director for postgraduate medical education of the Massachusetts Medical Society;

Mahlon Delp, M.D., Professor of Medicine and Director of the Department of Postgraduate Medical Education, University of Kansas School of Medicine;
James T. Howell, M.D., Director of Medical Education, Henry Ford Hospital, Detroit, representing Dr. Edwin Crosby, American Hospital Association;
Harold Jeghers, M.D., Professor of Medicine and Chairman of Department, Georgetown University School of Medicine (since moved to similar position at Seton Hall);
William B. Hildebrand, M.D., general practitioner, Menasha, Wisconsin, and former president, American Academy of General Practice;
Matthew R. Kinde, M.D., Director of Division of Medicine and Public Health, W. K. Kellogg Foundation;
Samuel Proger, M.D., Professor and Chairman of the Department of Medicine, Tufts University School of Medicine, President of Bingham Associates, and, in 1956, a member of the Continuation Education Committee of the Association of American Medical Colleges;
John Sheldon, M.D., Professor of Medicine and Director, Department of Postgraduate Medicine, University of Michigan School of Medicine;
Cassius J. Van Slyke, M.D., Associate Director, National Institute of Health;
Edward L. Turner, M.D., Secretary of the Council on Medical Education and Hospitals;
John C. Leonard, M.D., Director of Medical Education, Hartford Hospital (Conn.) and member Board of Governors, American College of Physicians, Chairman of Advisory Committee;
Glen R. Shepherd, M.D., Assistant Secretary of the Council on Medical Education and Hospitals, Secretary of the Advisory Committee.

The Guide Regarding Objectives and Basic Principles of Postgraduate Medical Education Programs which was the initial product of this Committee was published in July, 1957, following approval with minor revision by the House of Delegates. There continues to be a steady request for copies, despite wide distribution initially to medical schools, hospitals, medical societies, and others sponsoring programs.

It should be noted that the Introduction and the Summary in the Guide as approved by the House of Delegates contained the following sentence: "After a suitable period following publication of this Guide, a continuing appraisal of postgraduate programs may be initiated." After further intensive study of this during the past year, the Advisory Committee in its latest recommendations to the Council reiterated the following reasons for advocating a program of appraisal of the educational resources of institutions and organizations for postgraduate courses:

(1) High quality courses stimulate physicians to seek further education, while discouraging such an attitude is the physician's justifiable disappointment at the organization, quality, content, or methodology of a poor course;
(2) Appraisal would seem desirable in itself to indicate those courses which are educationally worthy of a physician's time and money;
(3) The present annual list of unappraised courses may be injuring the opportunity of raising educational standards in this field by giving tacit approval to some comparatively unsatisfactory activities;
(4) A continuing appraisal program, carefully conceived and flexibly implemented, that influenced the annual list would almost surely attract thoughtful attention to the basic guide as well as provide an additional incentive for the sponsors of programs to increase their educational merit; and
(5) Appraisal of postgraduate programs and the application of such appraisal to the preparation of the annual list of courses published in The Journal of the American Medical Association would be consistent with long-standing Council policies in listing medical schools, internships and residencies, that have been helpful in raising educational standards in undergraduate and graduate medical education.

It is considered impracticable if not impossible to appraise each postgraduate course separately. The most reasonable and effective approach is considered to be developing means of appraising the postgraduate educational resources and activities of the institutions and organizations sponsoring formal programs. Initially this will be limited to those sponsoring courses, using the Guide as a general reference. The studies and recommendations of the Advisory Committee and the staff are assisting the Council materially in formulating a program of appraisal and in testing it. Although the mechanisms developed appear to be satisfactory, only their further trial up to the point of publishing a selective listing of postgraduate courses can provide the data needed by the Council for further action.

The 57th Annual Report on Medical Education in the United States and Canada, prepared by the Council, contained a definitive analysis of postgraduate course activities and enrollments in the 1956-1957 year (*J. A. M. A.* 165:1431-1437 [Nov. 16] 1957).

A geographical study of postgraduate medical education centers and the origins of their physician enrollments is well advanced. It was begun in the summer of 1957 on the basis of data collected during the 1956-1957 year. When the geographical study is published, it is likely that it will provide new information useful to many who are concerned in the future planning of courses.

The current annual list, Postgraduate Courses for Physicians, will be published in The Journal Aug. 16, 1958, for courses in the year beginning Sept. 1, 1958. Occupying 58 pages, six more than last year, the list comprises 1,071 postgraduate course title listings. Considering that many courses are repeated during the year, more than 1,200 course offerings are listed. The annual list is based on inquiries each spring to all medical schools, hospitals approved for internship and/or residency training, medical societies, and other institutions and organizations in the United States. It is encouraging to note that a greater number of the sponsoring groups are planning postgraduate courses further in advance, are limiting enrollments, and consequently appear able to utilize more effective educational methods.

Educated in Related Fields

In recognition of the important contributions by professional and technical groups closely related to medicine to advances in knowledge, education, research, and the provision of comprehensive care to patients under the direction of physicians, the Council is responsible for continuous study and liaison on educational matters in a number of fields related to medicine. Continuing advice and assistance are given the Council by numerous medical organizations, such as the American Society of Clinical Pathologists and the American College of Radiology, as well as nonmedical professional and technical societies, in the development of sound criteria for training and approval of curricula. During the past year, the House of Delegates approved a revision of criteria for training medical technologists on which the Council received the essential advice of the Board of Schools of Medical Technology, Board of Registry of Medical Technologists, and Executive Committee of the American Society of Clinical Pathologists, and the American Society of Medical Technologists. The Council is currently engaged in approval of schools for medical record librarians, medical record technicians, medical technologists, occupational therapists, physical therapists, and x-ray technicians. Several hundred survey-visits are made annually to schools of medical technology and x-ray technology by pathologists and radiologists, who are appointed by the American Society of Clinical Pathologists and the American College of Radiology, respectively. These physicians generously contribute their time and experience to make these visits without remuneration. The education director of the American Association of Medical Record Librarians effectively surveys educational programs in universities and hospitals for medical record librarians and technicians. The educational committees and staff therapists of the American Occupational Therapy Association and the American Physical Therapy Association are active in evaluation and survey of medical schools, colleges, universities, and hospitals seeking initial and continued approval for occupational therapy and physical therapy curricula. Physician-therapist survey teams make these visits. As of June 30, 1958, there were 1,345 approved schools, which included 30 for medical record librarians, 11 for medical record technicians, 680 for medical technologists, 29 for occupational therapists, 37 for physical therapists, and 558 for x-ray technicians.

A jointly constituted Board of Trustees-Council Committee, with representation from the Council on Mental Health, entitled the Joint Committee to Study Paramedical Areas in Relation to Medicine, has under active study an exploration of ways in which closer liaison might be developed between physicians and closely related professional and technical groups. Initial conferences with more than 50 representatives of national medical organizations have been held during the past year and future conferences with professional and technical groups are planned.

Council Publications

The staff of the Council on Medical Education and Hospitals is responsible for the collection of information and compilation of data for four special issues of THE JOURNAL. These include:

Medical Licensure Statistics (1957), May 31, 1958
Postgraduate Courses for Physicians (Sept. 1, 1958-Aug. 31, 1959), Aug. 16, 1958
Directory and Annual Report of Approved Internships and Residencies (1958), Oct. 4, 1958
Medical Education in the United States and Canada (1957-58), Nov. 15, 1958

The Council staff also prepared special articles and editorials for THE JOURNAL and assists in editing the *Federation Bulletin* (published monthly by the Federation of State Medical Boards of the United States). The various "Essentials" in regard to education and training programs are constantly being subjected to study and revision and after approval of the House of Delegates are then published. These include:

Essentials for Approved Examining Boards in Specialties
Essentials of an Approved Internship
Essentials of Approved Residencies and Fellowships
Essentials of an Accredited School of X-ray Technology
Essentials of an Acceptable School of Physical Therapy
Essentials of an Acceptable School of Occupational Therapy
Essentials of an Acceptable School of Medical Technology
Essentials of an Acceptable School for Medical Record Librarians
Essentials of an Acceptable School for Medical Record Technicians
Functions and Structure of a Modern Medical School (replacing former Essentials of an Acceptable Medical School)

Currently available pamphlets and reprints, in addition to those listed above, include:

A Guide Regarding Objectives and Basic Principles of Postgraduate Medical Education
Choice of a Medical School
The Present and Future Status of Foreign Medical School Credentials in the United States
A History of the Council on Medical Education and Hospitals
Background and Development of Residency Review and Conference Committees
Selected Papers from the Annual Congress on Medical Education and Licensure (1958)

The Council staff also carries the responsibility for preparation of the listings which appear weekly in THE JOURNAL covering scheduled examinations and reciprocity meetings of the boards of medical licensure, basic science boards, examining boards in the medical specialties, and the qualifying examinations of the Educational Council for Foreign Medical Graduates.

Changes in Council and Staff Personnel and Organization

At the time of the June meeting in San Francisco (1958) Dr. Victor Johnson's term of eligibility for Council membership expired and the House of Delegates elected as his successor Dr. John Z. Bowers, Dean of the School of Medicine for the University of Wisconsin.

During the course of the year, Dr. Joseph J. A. McMullin retired from the field staff and Dr. Morris Weiss, an internist, joined the field staff. At the time of this report, there is one vacancy on the field staff for which a suitable candidate is being sought. Every possible effort is being made in the selection of these Council representatives to obtain individuals with the background and experience essential to their full appreciation of the problems with which they must deal in effectively evaluating programs of graduate medical education and training and in appropriately representing American medicine in the course of such activities.

On Aug. 1, 1958, Dr. Arthur N. Springall, Assistant Secretary of the Council resigned to become Director of Professional Services of the Veterans Administration Hospital at Oklahoma City. During the past two years of his five-year association with the Council, Dr. Springall has coordinated the activities of the field staff and served as administrative secretary of a number of the residency review committees. He was largely responsible for the establishment of the Internship Review Committee which has functioned so effectively during the past three years. Dr. Springall was succeeded on Aug. 1, 1958, by Dr. John C. Nunemaker who has directed the Education and Training Division of the Department of Medicine and Surgery of the Veterans Administration for the past several years. Dr. Nunemaker joins the staff as Associate Secretary and will be in direct charge of the graduate education and training activities of the Council.

Development and Needs

In the current setting there is need for constant re-evaluation of the activities of any organization such as the Council on Medical Education and Hospitals. Both the Council and its staff separately and collectively have endeavored to evaluate current activities and project needs for future activities as well as ways and means of rendering the best possible service to American medicine in the future. The Council believes that better intercommunication and closer liaison with other organizations concerned with medical education, research, and care, as well as closely allied fields, is essential to the best interests of all, and it will continue to exert itself to this end.

The Council is fully aware of the fact that there is room for improvement in every facet of its current responsibilities and will endeavor to continue to adjust its program to meet as effectively as possible the challenges with which it is presented. Basic medical education, graduate medical education, postgraduate medical education, as well as the interrelationship of education in areas closely allied with medicine, represent constant challenges necessitating continuing alertness, study, and adjustment. Top caliber personnel, fully aware of the changing scene and prepared to effectively aid in meeting and helping to solve these situations, will constitute a continuing need.

The rising costs on all sides of labor, printing, transportation, maintenance, and suitably qualified personnel will necessitate an augmented budget, simply to maintain the current level of activity.

Appreciation

The Council on Medical Education and Hospitals wishes to express deep and sincere appreciation to Dr. Victor Johnson for the outstanding contributions which he has made in the interests of the Council and of the American Medical Association. From 1943-1947 Dr. Johnson served as Secretary of the Council and from 1947-1958 has been one of its valuable and constructive members. His contributions in the interest of high standards in all areas of medical education have aided in the establishment of objectives which will be sought for many years to come.

Appreciation is also extended to Dr. Joseph J. A. McMullin for his contribution as a member of the field staff. Dr. McMullin has retired to his home in Riverside, Calif. The Council is grateful to Dr. Arthur N. Springall for his fine contribution and cooperation in the area of graduate medical education and extends the best of good wishes for happiness and success in his new assignment with the Veterans Administration.

The members of the Council and its staff are particularly appreciative of the fine work of Mrs. Anne Tipner and the personnel who work under her general supervision in conducting the routine activities of the headquarters office.

The support, encouragement, and cooperation which the Council has received from the Officers, Board of Trustees, members of the House of Delegates, other Councils and Bureaus of the American Medical Association, as well as that of the many organizations and agencies with which it has worked during the past year, are most sincerely appreciated.

Respectfully submitted,
Leland S. McKittrick, M.D., Chairman
Warde B. Allan, M.D.
John Z. Bowers, M.D.
W. Andrew Bunten, M.D.
Guy A. Caldwell, M.D.
John W. Cline, M.D.
Harlan English, M.D.
James M. Faulkner, M.D.
Charles T. Stone, M.D.
W. Clarke Wescoe, M.D.
Edward L. Turner, M.D., Secretary

Appendix A.—Functions and Structure of a Modern School of Basic Medical Sciences

I. Introduction

The Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association believe that two-year schools of Basic Medical Sciences under appropriate circumstances can make now and for the foreseeable future significant contributions to the established goals of medical education in the United States.

The increasing demands for medical services of a rapidly expanding and changing society can be served most effectively both by the development of new educational facilities in medicine and by the most efficient utilization of those facilities already in existence. Because of the early attrition of students and the ability of clinical facilities to accommodate greater numbers of students than basic science facilities, existing four-year schools can accept 300 to 400 more students for the last two medical school years than are presently enrolled.

The development of several new schools of basic medical sciences could result in the addition of more than 300 medical graduates annually. This increment would be obtained at least cost under these circumstances because of the lower capital and operating expenses of two-year programs and the more efficient utilization of already existing facilities for the last two medical school years. Students satisfactorily completing such two-year programs in the past have been successful in transferring to the third year classes of four-year institutions.

The initiation of new two-year programs should offer interesting and effective opportunities for furthering a closer and more meaningful relationship between liberal education and early education in medicine. The faculty and facilities of the basic medical sciences would add breadth and depth in biological disciplines important to much of the overall university program. One such significant feature would be the development of graduate degree programs in these sciences for the education of future teachers and investigators.

In view of these facts, the Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association wish to encourage universities with the necessary resources to establish new programs in medical education which would offer the first two years of the four-year medical course. These two organizations stand ready to consult with universities considering such a development.

It is intended that the following material be used as a guide in the development of two-year basic medical science programs with the hope that it may assist in attaining medical education of ever higher standards. Experience indicates that these are best nurtured in an environment in which there is not excessive concern with standardization. The concepts expressed here will serve as general but not specific criteria in the school accreditation program. However, it is urged that this document not be interpreted as an obstacle to soundly conceived experimentation in medical education including its administrative patterns.

While the terms "school" and "dean" appear throughout this statement, this is not done with the intention of placing sharp limitations around the manner in which a university may approach the development of a program offering the first two years of the medical curriculum. These are days of rapid growth in the breadth and depth of the knowledge important to medicine. As a consequence, if a university should wish to develop a program in the basic medical sciences within the framework of existing liberal arts and graduate resources, even relating this program to others in the social, biological and related physical sciences, the Council on Medical Education and Hospitals and the Association of American Medical Colleges will look upon such with great, albeit critical interest. The objectives of such an arrangement must be to raise educational standards as well as to conserve and make for the more effective and efficient use of faculty and physical resources.

II. The Responsibilities and Objectives of a School of the Basic Medical Sciences

As an institution of higher education, a school of the basic medical sciences has in common with four year medical schools three inherent responsibilities which are so closely related as to be inseparable.

1. It should provide for its students the opportunity to acquire a sound education in the sciences basic to medicine and should foster the development of lifelong habits of scholarship.
2. It should contribute to the advancement of knowledge through research.
3. It should contribute to the development of teachers, investigators and practitioners.

By virtue of its university orientation or as a result of the clinical facilities and personnel available, a school of the basic medical sciences should assume additional responsibilities such as those listed below to the degree that its resources permit without weakening its basic program:

1. Leadership in the development of adequate opportunities for the continuing education of practicing physicians.
2. Professional service to patients primarily to fulfill its educational and research obligations.
3. Participation in the educational programs of other professions in the health field, such as dentistry, nursing, and pharmacy, as well as in selected areas of the general university program.

4. Training of technical personnel in paramedical fields. The school should develop a clear definition of its total objectives. When these objectives are clearly defined, they should be made familiar to faculty and students alike, so that efforts of all will be directed toward their achievement.

A statement of "The Objectives of Undergraduate Medical Education" has been prepared by the Association of American Medical Colleges. It is believed that this can well serve as the basis for a definition of this portion of the overall objective of a school of the basic medical sciences and is reproduced in part below. The full statement can be found in the Journal of Medical Education (28:57-59, March, 1953):

"Undergraduate medical education must provide a solid foundation for the future physician's development. It should not aim at presenting the complete, detailed, systematic body of knowledge concerning each and every medical and related discipline. Rather, it must provide the setting in which the student can learn fundamental principles applicable to the whole body of medical knowledge, establish habits of reasoned and critical judgment of evidence and experience, and develop an ability to use these principles and judgments wisely in solving problems of health and disease.

"Undergraduate medical education cannot achieve these aims if the student is relegated to a passive role. It must provide incentive for active learning on the part of the student. This can best be done by giving him definite responsibility in real day-to-day problems of health and disease. This responsibility must, of course, be carefully graded to the student's ability and experience and must be exercised under careful guidance by the faculty.

"Given incentive to learn and guidance toward the grasp of principles, with the problems of health and disease as a frame for reference, the student will build the necessary foundation for his career in medicine, be it practice (general or limited), teaching, research or administration.

"In working toward this fundamental objective, undergraduate medical schools must strive to help the student to: acquire basic professional knowledge; establish essential habits; attain clinical and social skills necessary to the best utilization of that knowledge; and develop those basic intellectual attitudes, and ethical or moral principles which are essential if he is to gain and maintain the confidence and trust of those whom he treats, the respect of those with whom he works and the support of the community in which he lives.

"These . . . aims are obviously not distinctly separable, but are mutually interdependent. Altogether they summarize the desirable characteristics of the responsible professional person medical education is attempting to produce."

Though a school of basic medical sciences provides only half of the four medical school years, the objectives of the two year school should embrace the foregoing rather than be undesirably limited. Whether he be in a two-year school of the medical sciences or in a four-year medical school, the medical student is essentially a student at the graduate level who benefits most from an educational program having such an orientation.

III. Organization and Administration

A. Governing Body.—A school of the basic medical sciences is conceived as an integral part of a university which alone can provide the milieu and support required for medical study.

Officers and faculty of the school should be appointed by the University Board of Trustees. In keeping with generally accepted principles of administration, it is usually not desirable for a member of the board of trustees to serve simultaneously as an administrator or a member of the faculty of the school of basic medical sciences.

The manner in which the school is expected to conduct its affairs, including the responsibilities and privileges of administrative officers, faculty, and students should be clearly indicated in bylaws approved for the school itself or adequately presented in the bylaws of the parent university.

B. Administrative Officers of the School.—There should be competent supervision of the school of basic medical sciences by the dean or other executive officer who, by training and experience, is qualified to provide leadership in interpreting high standards in medical education, and who has sufficient authority to implement such standards. The dean should have the respect and support of the faculty and ready access to the university president and other officials. The establishment and maintenance of a congenial and productive relationship with the local medical profession is desirable and important to the school and the profession. It can be best assured through discussions of mutual problems by representatives of the school and practicing profession.

Because of the diverse and heavy responsibilities placed upon the dean or executive officer, assistance by suitably qualified persons should be provided. In some schools, for example, there is an assistant dean who devotes major attention to student affairs. In the conduct of the fiscal affairs of the school, the dean should have the assistance of a capable business officer.

C. Faculty Organization.—The faculty should be organized into suitable departments representing those areas or disciplines with a major responsibility in the teaching program. It is to be noted that this is primarily an administrative convenience; it should not form the sole basis for structuring the curriculum. Each such department should have a voice, through appropriate committees of the faculty, in the administration of the academic affairs of the school. Foremost among these should be an executive committee of the faculty composed primarily of the responsible administrative officials and the chairmen of those departments which have a major role in the education program. In a school of basic medical sciences usually these would be Anatomy, Physiology, Biochemistry, Microbiology, Pharmacology and Pathology. The clinical areas of Medicine, Surgery, Pediatrics, Obstretics-Gynecology, Psychiatry, and Preventive Medicine and Public Health may be represented singly or as combined areas. In the latter instance, consideration should be given to allowing a reasonable voice to clinical viewpoints in the committee's major function of determining, with the dean, medical school policies for consideration, where indicated, by higher university authority.

It is recognized that the clinical disciplines in a school of the basic medical sciences have quantitatively less responsibility in the total program of the school than do the clinical departments of a four-year medical school. In consequence, it is possible that the clinical departmentalization of the school of basic medical sciences might follow a different pattern than of having a separate department for each major clinical field, as is the case with four-year medical schools.

There should be such additional committees of the faculty as admissions, promotions, curriculum, postgraduate medical education, library, and others needed to serve the welfare of the school.

The entire faculty should meet one or more times annually to provide an opportunity for all faculty members to become acquainted with and to discuss school policies and practices.

Nominations for faculty appointments should originate in the faculty under the leadership of the dean. Commonly, nominations for appointments at the lower academic ranks are made by the head of the department concerned, after thorough discussions of the nominees by the entire department. At the professorial and associate professorial levels this procedure may be profitably supplemented or supplanted by the appointment of a nominating committee composed of members of several departments, whose standing and judgment are generally unquestioned. Recommendations are made to the faculty executive committee and dean who, in turn, recommend to the president and board of trustees through esablished administrative channels.

D. Finances.—Experience has established that a school of the basic medical sciences cannot successfully carry out its many activities solely on the income derived from student fees. Furthermore, certain of these activities are not directed primarily to the education of the medical student and he should not be expected to support them. To fulfill its obligation adequately a school of the medical sciences should have other substantial sources of revenue.

Each department within the school should prepare its budget in consultation with the dean, who is ultimately responsible for the total budget and its presentation to the proper authority.

IV. Faculty

The school should have a competent staff with demonstrated interest and ability in teaching and research. Such dual activity by the faculty is most likely to provide the educational milieu appropriate in a modern school of the basic medical sciences as well as to carry out best its objectives and responsibilities.

Reasonable security of tenure and possibility of advancement should be assured in order that the personnel of the faculty may have adequate stability.

The faculty in the basic science disciplines should be almost entirely on a full time basis. The number of such instructors in each basic science department should be sufficient to meet the requirements of the educational program as well as allow adequate time for research by each instructor. The ratio of full time basic science teachers to students may vary in different departments and different schools, depending on course content, educational methods, the nature and extent of research activities and other factors.

In addition, there should be a nucleus of faculty, adequately representing clinical interests, who have as their major responsibility the planning and supervision of the clinical aspects of the teaching program, its relationship to the basic medical sciences, as well as the conduct of research. The size of this nucleus and the specific clinical fields represented will depend, among other factors, on the number of physicians qualified and available to serve as part time and volunteer staff in the major clinical disciplines which will have significant teaching responsibility. Close contact of medical students with clinical teachers as the latter relate themselves to patients in a hospital setting will aid in the inculcation of the ethics and ideals of medicine at an early stage in the students' career.

Modern trends in medical education have resulted in interdigitation of teaching in basic science and clinical areas, so that the latter occurs to a significant degree and in the first two years of the curriculum. Similarly, basic science and clinical faculty members find a close and continuing relationship of great benefit in their research efforts. These desirable trends should find expression in a school of basic medical sciences to prevent it from being simply a "preclinical" institution.

Recognition of the value of intimate teacher-student relationships and widespread use of methods favoring an active role for the student in his own education have decreased dependence on didactic exercises. Increasing use has also been made of interdepartmental teaching. These factors have tended to increase the size of the instructional staff.

V. Students

The admission of students to a school of the basic medical sciences should be the responsibility of a committee of the faculty. Decisions regarding admission should be based not only on satisfactory prior scholastic accomplishment but also on such factors as personality and emotional characteristics, motivation, industry, resourcefulness, and health. Evaluation of these factors should be developed through personal interviews, college records of academic and non-academic activities, results of medical college admission tests, and pertinent letters of recommendation. All records dealing with admissions should be carefully filed and procedures periodically reviewed in a search for better methods. Of assistance in this would be the securing of information regarding student achievement from the four-year medical schools to which the students of the two-year school transferred.

At least three years of college education is required for most students and four years is recommended as a preparation for medical study. Only rarely and under exceptional circumstances will a medical school be justified in admitting a superior student after two years of college study. The National Committee of Regional Accrediting Agencies maintains a listing of institutions of higher education which have been found to offer commendable educational programs. (A copy can be obtained by addressing the National Commission on Accrediting, 1785 Massachusetts Ave., N. W., Washington 6, D. C.) Prospective medical students should acquire their preparatory education at a college of arts and sciences so listed. The admissions committee of a school of the basic medical sciences should scrutinize with particular care the qualifications of applicants whose preparatory study has been done at other institutions.

Because basic knowledge of biology, physics, inorganic and organic chemistry and human behavior are the foundation stones of medicine, adequate college courses in these subjects, as well as demonstrated competence in English, should be required. It is important that any medical college restrict its admission requirements to this minimum so that a college student preparing for the study of medicine will have the opportunity to acquire a broad liberal education or to study a specific field in depth according to individual interest and ability. The complexity of modern medicine can be served best by physicians who in composite represent a variety of backgrounds in education and experience.

The number of students who can have an adequate medical education in the first two years is related to the laboratory and clinical facilities available and to the size and qualifications of the teaching staff (see also: *IV. Faculty*). A close personal contact between students and members of the teaching staff results in a quality of educational experience that is not possible in an institution where the number of students is excessive in relation to the staff and facilities.

There should be a system of student records showing conveniently and in detail the admissions credentials as well as the grades or other records of performance in the school, by means of which an exact knowledge can be obtained regarding each student's work and qualifications. Subjective evaluations of each student by instructors should be included in the student records.

An adequate provision for student counselling should be in effect. Many schools have an assistant responsible to the dean for such counselling.

There should be an active student health service providing for periodic medical examination and medical care for the student body. This is important not only in the maintenance of student health but also because of its inherent educational values.

VI. Facilities

A school of the basic medical sciences should own or enjoy the assured use of buildings and equipment adequate quantitatively and qualitatively to provide an environment most conducive to productivity of faculty and students in the fulfillment of the total objectives of the school. If possible, all of the basic medical sciences should be housed in a building close enough to the clinical facilities so as to promote cooperative teaching efforts and allow all departments ready access to clinical material.

A well maintained and catalogued medical library that can be used conveniently and effectively by both students and faculty is essential to modern medical education. A trained librarian with experience in medical library work should be employed to supervise the development and operation of the library with the advice and assistance of an active representative committee of the faculty. The library should receive regularly the leading medical periodicals, the current numbers of which should be readily accessible. Adequate arrangements should be made by the librarian and the faculty to instruct all students in the use of the library at the beginning of their medical studies.

The school should have the assured use of a number of hospital beds adequate to meet the clinical needs of the teaching program. It is essential that the clinical teachers, either on nomination by the school or by agreement in conference between school and hospital, be appointed by the hospital trustees to appropriate positions on the hospital staff so that their direction of the teaching service will be unquestioned. It is desirable for the teaching hospital to be in close proximity to the school and it should provide sufficient patients for instruction in physical diagnosis and to introduce students to the clinical study of disease as well as to illustrate the clinical aspects of the basic medical sciences.

There should be sufficient offices, laboratories, and conference rooms in the basic science facility and either as a part of or conveniently close to the hospital to meet the needs of faculty and students.

VII. Educational Program

Before the curriculum, methods and details of an educational program are determined, the objectives of the program should be formulated. The objectives should indicate clearly that the first two years of medical education are to provide the foundation for further education in a four-year medical school, in graduate programs, as well as throughout professional life. There is no objection to the awarding of an appropriate degree when indicated.

The educational program of a school of the basic medical sciences must, in part, be conditioned by the general pattern of the first two year curriculum of four-year schools. However, the program should be structured primarily to provide students with an opportunity to acquire a sound background in the basic medical sciences and an introduction to the major clinical disciplines. Because of the variations present in the curriculum of different medical schools, any attempt by a school of basic medical sciences to embrace the variations present in several four-year medical schools would lead to a confused preoccupation with coverage of the details of many subjects. This would hamper the students' acquisition of an understanding of basic principles upon which they can structure necessary facts and would inhibit the important development of sound attitudes of self-education and essential habits of reasoned and critical judgment.

No rigid curriculum can be prescribed for accomplishing the objectives of medical education. On the contrary, it is the responsibility of the faculty of each school continually to reevaluate its curriculum and to provide in accordance with its own particular setting and in recognition of advances in science a sound and well-integrated educational program. Each school should utilize those methods and approaches that the particular interests and abilities of the faculty indicate would provide the most effective education in the framework of the available facilities. The traditionally separate disciplines are finding rewarding educational and research results in working together co-operatively.

Through the various educational methods and to the extent deemed best by the faculty to accomplish the objectives of medical education, each school of basic medical sciences should offer education in the following subjects during the two-year curriculum:

Human anatomy, biochemistry, physiology, microbiology, pharmacology, general pathology, physical and laboratory diagnosis, as well as an introduction to clinical medicine, surgery, obstetrics-gynecology, pediatrics, psychiatry, and preventive medicine and public health as appropriate to the curriculum of the first two years. Biostatistics and medical genetics should be included in the educational program, as also should an initial consideration of social, emotional and environmental factors in health and disease.

The traditional emphasis on lectures, demonstrations and amphitheater clinics in which the role of the student is passive has shifted to greater use of individual student and small group projects, conferences, seminars, and the "case method" of education, in all of which the student actively participates in his own education. The allotment of some unscheduled student time in the weekly program to allow for reading, research or other independent pursuits is desirable.

VIII. Accreditation of Medical Schools

The American Medical Association through its Council on Medical Education and Hospitals and the Association of American Medical Colleges through its Executive Council serve as the recognized accrediting agencies for medical schools and for schools of the basic medical sciences. Though retaining their individual identities, both groups work very closely in this activity through the Liaison Committee on Medical Education. To be accredited, a school must be considered approved by the Council on Medical Education and Hospitals and by the Association of American Medical Colleges. Accreditation is granted on the observance of a sound educational program in a survey visit conducted jointly by both organizations.

It is the intent that newly developing two-year schools should be surveyed during each of the first two years of active existence, with definitive action taken during the implementation of the second year of the curriculum.

Existing medical schools are surveyed at regular intervals. Every attempt is made to fulfill requests for interim surveys as a consultant service to the medical schools and schools of basic medical sciences.

A school to be surveyed is requested to provide basic information on forms forwarded in advance. After careful study of this material, a joint survey team visits the school. On completion of its visit, the survey team confers with the responsible administrative officials of the school of basic medical sciences and its parent university, indicating to them the nature of the major findings and recommendations. A complete, written report is prepared and considered separately by the Council on Medical Education and Hospitals and the Executive Council of the Association of American Medical Colleges and then jointly by the Liaison Committee on Medical Education. The action of each group and the complete report is then transmitted to the school dean and the university president.

Application for and further information concerning this process can be obtained from the Secretary Council on Medical Education and Hospitals, American Medical Association, 535 N. Dearborn St., Chicago 10, or the Executive Director, Association of American Medical Colleges, 2530 Ridge Ave., Evanston, Ill.

Appendix B.—Essentials for Residency Training in Urology

Residency instruction in urology should be systematic and progressive in character to the end that adequate training may be obtained in diagnosis, therapy, cystoscopic examinations, pyelography and operative procedures, all under the supervision of a well qualified urologist. Such a progressive type of instruction predicates continuity of supervision by the Head or Chief of Service for a sufficient number of years, which ideally constitutes a length of service of three to five years or longer, to assure stability in the direction of the educational program. The position of Chief of Service should not be an honorary appointment, but should be held by the urologist best fitted for this responsibility. The urologic staff should be composed of urologists who are highly qualified in both surgical skill and judgment. It should be organized and harmonious, with the designated Head or Chief of Service responsible for the quality of work done in the department. The members of the staff should have a real interest in teaching and the welfare of the residents, and must be willing to give the time and effort required by the educational program. Teaching rounds and departmental conferences are essential for systematic clinical instruction. As preliminary training for residencies and fellowships in urology, the Residency Review Committee recommends one year of internship and one year of training at the graduate level in surgery, medicine, or a related basic science. It is acceptable that any formally integrated service may permit some variation on the one year basic science, general surgery, and internal medicine requirement, provided it is completed prior to the senior year.

The department must provide adequate facilities for surgery and special urologic procedures. Training in surgical technic should be sufficient to enable residents to undertake operative work on their own responsibility, especially toward the end of the residency program.

The clinical material should be sufficient in amount and variety to fulfill the teaching needs of the service. Hospital patients should be supplemented by outpatient material in cystoscopic and general urologic clinics.

Quantitative Requirements

Ordinarily a minimum of 200 inpatients a year is necessary for acceptable residency training in urology.

Applied Basic Science Instruction

Instruction in the applied basic sciences can readily be integrated with the clinical experience. This should be supplemented by conferences in embryology, anatomy, physiology, microbiology, endocrinology, radiology, and biochemistry. Particular emphasis should be placed on the study of pathology and residents must be required to examine both grossly and microscopically all urologic specimens removed during his term of service. Such work should be closely correlated with the clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

The provisions of the section General Requirements (pp. 6 to 17) must also be met for approval.

Residents who plan to seek certification by an American Board should communicate with the secretary of the appropriate board, as listed in Section V, to be certain regarding the full requirements for certification.

COUNCIL ON MEDICAL SERVICE

This report covers the fiscal year June 30, 1957, to July 1, 1958. All activities taking place during the summer and fall of 1958, which seem to warrant the immediate attention of the House of Delegates, will be included in a supplemental report to the House.

The Council on Medical Service and its eight committees held twenty meetings and six regional conferences during the year. Most of the meetings were held in Chicago, as the most convenient place for both physicians and the staff. However, 4 meetings and 5 regional conferences were held elsewhere, either as a convenience to state medical association representatives or to permit Council and committee members to get in closer touch with regional and local opinions and attitudes.

Several times in the past the Council has reviewed the make-up and method of operation of its eight committees and it does not seem necessary to review this again at this time. However, the Council would like officially to express the appreciation to the members of these committees for the time and interest each has devoted to the study of problems under consideration. Over 60 physicians and consultants serve without remuneration and frequently at a personal loss in both dollars and "family" or "leisure" time. And, surprisingly enough, it is a rare occasion when a Council meeting or a committee meeting does not have 100% attendance. In addition, the Council would like to express its appreciation for the time given by the several hundred physicians who attended the regional conferences to discuss specific projects and activities. The Council looks upon its primary objective as that of representing the practicing physician. To accomplish this, those active in the A. M. A. must understand the problems of the practicing physician and the practicing physician must understand the problems of the A. M. A. Both the committee structure and regional conference approach provide what might be termed a "two-way street" for a better understanding by all concerned.

The Council also wishes to point out that its staff serves other committees within the Association. Among those served during the year, either in part or in full by Council staff members are: Commission on Medical Care Plans, Committee on Medical Practices, Task Force on Dependent Medical Care, Committee on Relationships Between Medicine and Allied Health Agencies, Committee on Medical Rating of Physical Impairment, and the Medical Advisory Committee to the Sears-Roebuck Foundation. In this latter task, the staff was instrumental in developing a new book entitled "The Business Side of Medical Practice" designed to help the young physician in establishing his practice. The Council is distributing this book to senior medical students, interns, and residents through the state and county medical societies.

Finally, the Council would like to express its appreciation to the Board of Trustees for approving the appointment of Mr. George W. Cooley as Secretary of the Council on Medical Service to fill the vacancy created by the resignation of Mr. Thomas A. Hendricks. Mr. Hendricks in December, 1957, became Field Director for the American Medical Association. Mr. Cooley had been Mr. Hendricks' assistant and associate for over twelve years and will, we are confident, continue the many projects and activities which Mr. Hendricks so ably began.

On the following pages of this report the House of Delegates members will find a review of some of the activities of the Council and its committees, covering the past year.

Committee Reorganization

The original committees of the Council on Medical Service were created by the House of Delegates in 1948. These Committees are composed of physicians, either especially qualified or having a special interest in the area covered by the committee concerned. They bring to committee work a wide range of opinions and viewpoints, representing different geographical areas, different specialties, and different types of medical practice. One committee has been added since 1948 and the names of several of the committees have been changed. However, the general structure has remained as originally authorized by the House. Recognizing that new interests and new problems have arisen the past few years, bringing about a need for increased emphasis in some areas as well as new activities in others, the Council had, for some time, considered reorganization of this committee structure. With this in mind a major change has been made in reference to insurance and prepayment plans.

Because of the special interest of Dr. Milford O. Rouse and the Texas Delegation in increasing the Association's activities in reference to all forms of insurance and prepayment, the Council held its March, 1958, meeting in Texas to discuss these problems further.

Since any reorganization of Committee structure requires action by the Board of Trustees, the Council reported in full on this matter to the Board of Trustees and made the following recommendations:

1. That the activities of the present Committee on Prepayment Medical and Hospital Service and the Committee on Relations with Lay Sponsored Voluntary Health Plans be combined into a new committee entitled "Committee on Insurance and Prepayment Plans" to handle all problems in reference to:
   - I. Insurance Per Se, Written By
     - A. Private Insurance Companies, and including such coverages as:
       - 1. Medical-Surgical
       - 2. Catastrophic or Major Medical
       - 3. Health and Accident (time loss)
       - 4. Professional Liability
       - 5. Life
     - B. Blue Shield and Blue Cross Plans of the straight indemnity type
   - II. Prepayment Health Care Plans, *including*
     - A. Vendor Sponsored Plans, such as:
       - 1. Medical society (including Blue Shield) plans with "service" features, and
       - 2. Blue Cross plans with "service" features
     - B. Consumer or Lay Sponsored Plans, such as:
       - 1. Health Insurance Plan of Greater New York
       - 2. Cooperatives providing or arranging for medical-hospital care
       - 3. Group Health Association, Washington, D. C.
2. That the present Committee on Medical Care for Industrial Workers, a joint committee of the Council on Medical Service and Council on Industrial Health, be retained to handle all problems in reference to:
   - III. Non-Insurance Medical Care Plans, *including*
     - A. Plans Sponsored by Unions, such as:
       - 1. U. M. W. A. Health and Welfare Program
       - 2. Union Health Centers
     - B. Plans Sponsored by Industry, such as:
       - 1. Medical Care Plans in Industry
       - 2. Employee Benefit Plans
       - 3. Railroad Hospital Plans
3. That the Council be authorized to employ a recognized authority in the field of insurance as director of the Committee on Insurance and Prepayment Plans who can act as spokesman for the A. M. A. in this field and can plan and direct such research as is necessary to promote the best interests of the public and the profession.

With a recognized authority as director of a Committee on Insurance and Prepayment Plans the Council proposes to divide the work into two phases:

(1) Section A under Category I, Insurance—Per se; and

(2) Section B under Category I and Sections A and B under Category II, Prepayment Health Care Plans, with adequate staff to serve each phase.

In reference to the above recommendations the Council wishes to point out that it has already increased its staff personnel to step up activities in these areas as well as in the areas of Aging and Medical and Related Facilities. So far, four additional staff members have been added, all of whom are well qualified in handling various aspects of the Council's work.

The Board of Trustees approved the establishment and name of the new Committee and requested a conference with the Council as to the size and membership of the Committee.

The result of this conference was:

1. The establishment of a new Committee on "Insurance and Prepayment Plans" combining the functions of the Committee on Prepayment Medical and Hospital Service and the Committee on Relations with Lay Sponsored Voluntary Health Plans.
2. The Committee to be composed of nine physicians, with one year tenure.
3. Approval of the employment of an individual experienced in the field of insurance to head up the Committee's activities and such additional staff as is needed to carry on the necessary activities in the prepayment field.
4. Approval of the use of technical advisors or consultants from the various insurance and prepayment fields.

During the summer and fall the Council will name the Committee members, the technical advisors, and employ the necessary staff.

Committee on Aging

MEMBERSHIP

This Committee has had two membership changes during the year: Although he will continue as a member of the Committee, Dr. H. B. Mulholland, Charlottesville, Va., for reasons of health, was replaced as Committee Chairman by Dr. Frederick C. Swartz, Lansing, Michigan; Dr. David B. Allman, Atlantic City, N. J., was added. Other members are: Drs. Edward L. Bortz, Philadelphia; Henry A. Holle, Austin, Texas; Wingate M. Johnson, Winston-Salem, North Carolina; Theodore G. Klumpp, New York City; Cecil Wittson, Omaha; and J. D. McCarthy, Omaha, ex-officio. Staff members are Mr. George W. Cooley, Secretary, Mr. John Guy Miller, Research Associate, Mr. Herbert B. Norton, Research Assistant, and Mr. Arthur Broadwin, Research Assistant.

A. M. A. HEALTH PROGRAM FOR OLDER CITIZENS

Perhaps the most realistic and far reaching achievement of this Committee during the current year lies in the development of "a positive program." As the multiple problems in the area of the aging became more distinct, there developed a realization that A. M. A. must reaffirm its leadership in this important area, and that such leadership, in order to be most effective, must be translated into action by the constituent and component medical societies.

While the positive program is still undergoing revision prior to its general publication, it calls for medical society action at national, state and local levels in the interest of the following objectives:

1. Stimulation of a realistic attitude toward aging by all people.
2. Extension of effective methods of financing health care for the aged.
3. Expansion of skilled personnel training programs and improvement of medical and related facilities for older people.
4. Promotion of health maintenance programs and wider use of restorative and rehabilitative services.
5. Amplification of medical and socio-economic research, in problems of aging.
6. Cooperation in community programs for senior citizens.

The constituent and component medical societies will be presented with the substance of this program at the National Conference in September. (cf: A. M. A. Planning Conference on Medical Society Action in the Field of Aging—this report)

EXHIBIT

An exhibit is being planned which will be based on the "6 point program" and it is scheduled to be ready for the National Conference in September. Other commitments to show it include (1) Annual Meeting of the Gerontological

Society in Philadelphia, November 6-8, 1958 and (2) A. M. A. Clinical Session, Minneapolis, December 2-5, 1958. At a later date the exhibit may be made available on a loan basis to the state and county societies.

REGIONAL MEETINGS

It was pointed out in the 1957 annual report that a series of regional meetings was inaugurated at Seattle during the A. M. A. Clinical Session in November, 1956. This was followed by similar meetings at Dallas, Texas in April, 1957; Philadelphia in December, 1957; Birmingham, Alabama in March, 1958 and Omaha, Nebraska in May, 1958.

Each regional meeting was attended by physician representatives from the medical societies (both state and local) of from 8 to 12 of the contiguous states in each area. The programs were specifically geared to audience participation and discussion. The Committee members were informed of the problems at the state and county levels and of what state and local committees on aging were seeking, in the form of guidance, from the A. M. A. Committee. Further, those attending the meetings were given specific information relating to the various aspects of the problem and a review of what is being done, what can be done and suggestions as to how to do it. Such data have been summarized in printed form and are available on request.

A. M. A. PLANNING CONFERENCE ON MEDICAL SOCIETY ACTION IN THE FIELD OF AGING

The Committee was sufficiently encouraged by the interest manifested at the regional meetings to feel justified in holding a national conference for the benefit of all the state and local medical organizations. This conference at the Drake Hotel, Chicago, September 13 and 14 will be discussed more fully in the supplementary report of the Council.

GUIDES FOR MEDICAL SOCIETY COMMITTEES ON AGING

One of the principle objectives of the regional meetings was to stimulate the creation of committees on aging by all state and county medical societies; further, the A. M. A. House of Delegates, on the recommendation of this Committee, at the Clinical Session in December, 1957, "urged every state medical association to create a committee on aging or to assign this problem to an existing committee." In view of this and also in response to many requests for guidance from both state and county medical societies, this Committee has published "Suggested Guides For Medical Society Committees on Aging."

JOINT COUNCIL TO IMPROVE THE HEALTH CARE OF THE AGED

This Council, which was created during the current year, is composed of the American Medical Association, the American Dental Association, American Hospital Association, and the American Nursing Home Association. The objectives of the Council are listed as follows: (1) to identify and analyze the health needs of the aging; (2) to appraise available health resources for the aging; and (3) to develop programs to foster the best health care for the aging regardless of their economic status. The Joint Council is expected to serve as a coordinating mechanism for discussion and planning purposes.

This Committee has endorsed the Joint Council in principle and recommended that, wherever feasible, similar units be established at the state level.

Liaison at the staff level has been established and will be maintained between the Joint Council and the Committee on Aging.

LIAISON WITH OTHER GROUPS

On September 15, 1957, the Committee met in Washington with representatives of the American Psychological Association and on September 16 with representatives of those Federal Agencies interested in aging.

As indicated in the annual report of 1957, the meeting with the American Psychological Association was arranged because of this Committee's interest in "*Retirement (Aptitude Tests—Medical Yardsticks).*" Further, "the Committee believes that retirement should not be based on chronological age. . . ." The conferees examined the present status of psychological technics and the extensive research that is being conducted in this area.

COMMITTEES ON AGING—STATE MEDICAL ASSOCIATIONS

This Committee has consistently reminded each state association, without a committee, of the desirability of creating one. In January, 1956, in response to a questionnaire, only 16 of the 37 reporting state associations had specific committees on aging or had assigned this problem to an existing committee. At this time 33 state medical associations report a committee on aging or that the problem has been assigned to an existing committee. Further, this Committee is informed that 10 additional state associations will have created such committees by the early fall bringing the total to 43.

Under the title "Liaison with Federal Government and National Agencies" in the 1957 annual report, it was stated that "A Federal Council on Aging has been created representing 12 departments and agencies." This has now been increased to 13 departments and it was with representatives of 7 of these agencies that this Committee met in Washington, D. C., on September 16, 1957. The departments represented were: (1) Center for Aging Research, National Institutes of Health; (2) Small Business Administration; (3) Veterans Administration; (4) Bureau of Employment Security, Department of Labor; (5) Housing and Home Finance Agency; (6) Employee Relations and Planning, Civil Service Commission; and (7) Public Health Service.

Transcripts of the proceedings of this meeting as well as of the meeting with the American Psychological Society have been published (cf: "Publications"—this report).

This Committee has followed closely the activities of other national groups interested in Aging. It has maintained liaison with and attended national and regional meetings of: (1) U. S. Public Health Service; (2) Division on Gerontology, University of Michigan; (3) Council of State Governments; and (4) The National Committee on Aging of the National Social Welfare Assembly.

U. S. Public Health Service.—The U. S. Public Health Service has conducted a series of 7 regional conferences. These seminars were primarily to acquaint the personnel of state health departments with preliminary plans and to prepare them for active participation in more detailed planning which is scheduled to follow. This Committee cooperated by communicating with the state medical associations in each region prior to the conference, and urged them to be represented. According to reports, such representation fell short of what should be expected.

Staff attended the regional seminar in Chicago on June 20, 1957. The underlying theme of all of the sessions was that the problems of the aging and aged are community responsibilities and cannot be delegated to any one agency or segment of society, but must be shared by all in a spirit of aggressive cooperation.

Division of Gerontology, University of Michigan.—Staff attended the 10th Annual Conference in Ann Arbor on June 24-26, 1957. The theme of this conference was "Retirement and Leisure Time." The contributions on the part of the speakers were essentially academic in substance. The Conference, however, pin-pointed three important factors.

(1) The complexity of the problem.
(2) The paucity of applicable and practical solutions.
(3) The wide and general recognition of the problem, and a sincere desire to do something about it on the part of trained personnel who should have the "know how" with regard to working out some solutions.

Council of State Governments.—Staff attended regional meetings at Cleveland, Ohio on July 22-24, 1957, and at Atlanta, Georgia, on February 28-March 1, 1958.

About three-fourths of all of the state governments now have committees concerned with the problems of the aging, but many are of an interim or *ad hoc* tenure. Many states have study commissions and inter-departmental coordinating agencies. As evidenced by the resolutions passed at these regional conferences urging the governors of the several states to take definite action in this area, there is aggressive effort being made to strengthen the structures and accelerate the activities of these committees.

The National Committee on the Aging of the National Social Welfare Assembly.—This Committee of the National Social Welfare Assembly is broadening its scope both in the areas of its activities and in the area of research: Its last meeting, which was attended by staff, was held in Washington, D. C. on March 13-14, 1958. The substance of the conference was in terms of the political and social aspects of the problems incident to aging.

NURSING HOMES

The nursing home is the indicated facility for those elderly patients whose infirmities do not qualify for care in a general acute disease hospital and where home care is not available or feasible.

This presents a challenging problem area, and this Committee, in cooperation with the Committee on Indigent Care and the Committee on Medical and Related Facilities, has established an active and continuing liaison with the American Nursing Home Association. (This Committee recommended, and the Council approved, that state committees on aging may serve as the group to have liaison with state nursing home groups).

Committee and staff members attended a conference on "Long Term Care" sponsored by the American Hospital Association and the Public Health Service and during the past year, the U. S. Department of Health, Education and Welfare sponsored by a "National Conference on Nursing Homes and Homes for the Aged."

Other Joint Committee activities regarding Nursing Homes are covered elsewhere in the Council report.

PUBLICATIONS

(1) A series of 11 articles on various aspects of the problems in the field of aging was published in the J. A. M. A.

(2) "Health Aspects of Aging"—a brochure including the above 11 articles and in addition an article by H. B. Mulholland, M.D., on "Aging and Chronic Illness."

(3) "Suggested Guides for Medical Society Committees on Aging". These guides discussed previously in this report cover the following areas: (1) Purpose; (2) Membership and Format; (3) Tenure; (4) Meetings and (5) Activities.

(4) "Proceedings of the Regional Meetings of the Committee on Aging" Philadelphia—March 19-20, 1956
Seattle, Washington—November 27, 1956
Dallas, Texas—April 27-28, 1957

(5) "Proceedings of the Committee on Aging"
I. With American Psychological Association
September 16, 1957, Washington, D. C.
II. With Federal Agencies Interested in Aging
September 16, 1957, Washington, D. C.
III. Regional Meeting
December 2, 1957, Philadelphia, Pa.

(6) "Proceedings of the Regional Meetings of the Committee on Aging"
Birmingham, Alabama—March 29-30, 1958
Omaha, Nebraska—May 24-25, 1958

The proceedings of regional meetings offer a cross section in discussion form of what some physicians and educators are thinking in the area of the problems of the aging and aged.

Further, in preparation, is a series of articles on the activities, in the field of aging, of the federal and state governments and other national lay organizations; it is planned to publish the series in the J. A. M. A.

CHRONIC ILLNESS NEWSLETTER

The Council has continued bi-monthly publication of the Chronic Illness Newsletter during the past year. In August, the mailing list was revised and brought up to date by mailing return postal cards to the 12,000 individuals and organizations who were receiving the Newsletter. Approximately 6,500 cards were returned, and this group constitutes the present mailing list, representing a cross-section of the medical and allied health fields. Emphasis in the Newsletter continues to be placed on specific local community programs and approaches to the different problems in the area of long-term illness, and from all indications the publication is well received and used. All material continues to be supervised by the Editorial Advisory Committee, composed of Dr. Henry B. Mulholland, Dr. Dean W. Roberts, and Mrs. Lucille Smith, former members of the National Commission on Chronic Illness, and Dr. Edward L. Bortz, a member of the Council's Committee on Aging.

Committee on Federal Medical Services

The membership of the Committee has undergone two changes during the past year. At the December 1957 session in Philadelphia, Dr. Henry S. Blake of Topeka, Kansas was added to the membership, and at the June 1958 session in San Francisco, Dr. Russell B. Roth of Erie, Pennsylvania was elected Chairman of the Committee, to replace Dr. Louis M. Orr of Orlando, Florida, now president-elect of the American Medical Association.

Other members are Drs. Donald C. Conzett, Dubuque, Iowa; J. Lafe Ludwig, Los Angeles; Richard L. Meiling, Columbus, Ohio; Vincent W. Archer, Charlottesville, Va.; Oscar B. Hunter, Washington, D. C.; and J. D. McCarthy, Omaha, ex-officio. Staff members are: Dr. William J. Kennard, Washington, D. C., and Mr. C. Joseph Stetler, Chicago, consultants; Mr. George W. Cooley, Secretary, and Mr. James H. Fleming, Research Assistant.

The Committee on Federal Medical Services met twice during the period from July, 1957 to June 30, 1958. Meetings were held at Philadelphia on December 2, 1957, and at Chicago, on June 7, 1958. Dr. Orr, then Chairman of the Committee, also held a staff conference at Chicago on February 6, 1958.

A. M. A. POLICY ON VETERANS' MEDICAL CARE

The policy adopted by the House of Delegates in November, 1956 in regard to veterans' medical care stated that Veterans' Administration facilities should be used only for the care of service-connected diseases and disabilities, and that the care of non-service-connected conditions should be the responsibility of the individual, or, if he is medically indigent, of his community or state. It further stated that, until existing law is changed, priority for any non-service-connected care provided should go to those suffering from illnesses or disabilities which are economically catastrophic.

At the June, 1958 session of the House of Delegates this policy was further amplified by the adoption of a resolution that the House should "urge congressional action to restrict hospitalization of veterans at VA hospitals to those with service-connected disabilities." The resolution further stated that the American Medical Association should suggest to the Dean's committees "that they restrict their activities to Veterans Administration hospitals admitting only patients with service-connected disabilities."

MEDICAL SOCIETY RESPONSIBILITY

In its 1957 report, the Committee recommended that further emphasis be placed on the June, 1957 reference committee recommendation that "it will be to the best interests of the public in general, and veterans in particular, if medical societies, county and state as well as national, develop committees to assist in guaranteeing VA hospital admission to service-connected cases." It also called attention, at that time, to the House's recommendation that the medical profession should help assure "that veterans whose illness constitutes economic disaster will not be displaced by those suffering short-term remediable ills which, at the worst, constitute financial inconvenience." At the Philadelphia meeting (December, 1957), the reference committee also emphasized this request and urged state medical associations to report to the Council on Medical Service any activities in this regard. In the Committee's opinion, the June, 1958 resolution on veterans' care does not nullify this recommendation as to procedure under existing laws.

The Committee considers it essential, if the medical profession's recommendations in regard to veterans' medical care are to be considered seriously by the general public and the Congress, that concrete evidence be provided of the profession's very real concern for the care of the veteran with service-connected diseases and disabilities and for those who are truly unable to pay for care. It also feels that the activities recommended at the Philadelphia session would very clearly demonstrate that the policy on veterans' medical care is part of a positive program for the health of the entire nation. However, it regrets to report that, during the six-month period, January to June, 1958, after this recommendation was adopted by the House, no activity of this sort has been reported to the Council on Medical Service.

The Committee therefore wishes to repeat its recommendation that state and county medical associations establish organized programs to assure observance of these priorities, and to urge most strongly that the Council on Medical Service be kept informed of all such activities, so that they may be reported at the national level.

HOMETOWN MEDICAL CARE

The latest annual report of the Veterans' Administration shows 584,114 outpatient visits to fee-basis physicians during fiscal year 1957, better than one-fourth of all out-patient visits. In terms of visits for treatment, rather than for examinations, fee-basis physicians provided over one-third of the out-patient care. The total number of out-patient visits to fee-basis physicians decreased from fiscal year 1956 to fiscal year 1957 by about 3.4 per cent. However, since the visits to Veterans' Administration out-patient facilities decreased by a like amount (3.6%), it appears that the decline is probably due to a gradual falling-off in the service-connected case load, rather than to a decrease in emphasis by the Veterans' Administration on the Hometown Medical Care program.

The Veterans' Administration has, during the past year, introduced several changes in the Hometown Care program, apparently designed primarily to reduce the amount of administrative paper-work required. The two major changes introduced involve extended authorizations to private physicians for treatment of long-term cases and the authorization of informal agreements, negotiated between state medical associations and VA regional office Chief Medical Directors, to replace direct contracts. The latter change, effective July 1, 1958, means that only those states with intermediary contracts, in which a third party administers the program, will have to negotiate contracts with the VA central office.

CONFERENCE ON VETERANS' AFFAIRS

At the Philadelphia session, the House endorsed the Committee's proposed national conference on veterans' affairs, to be held in 1958. At this conference, it is planned that time will be allowed for a thorough discussion of the Hometown Medical Care program and the problems involved. The Committee also proposes, at this conference, to discuss other aspects of the problem of veterans' medical care and methods of further implementing the medical profession's policy, both at the national and the local level.

Decision as to date and place of this conference is not yet final; it is expected that further information will be presented in a supplementary report to the House.

MEDICAL CARE FOR CIVIL SERVICE EMPLOYEES

At the December, 1957, session, the report of the Reference Committee on Insurance and Medical Service included the following comment on this Committee's report: "it is interesting to note that the alleged abuses in Bexar County (Texas) were corrected after the recommendations were adopted, but in recent months a change of post command resulted in the reinstitution of former practices of medical care for Civil Service employees. Appropriate steps are being taken to remedy the situation."

In pursuance of this objective, the matter was brought to the attention of Major General Dan C. Ogle, Surgeon General of the Air Force. In December, 1957, General Ogle notified the Association that "definite steps are being taken to re-evaluate and realign the occupational program at Kelly (Air Force Base) so that it will coincide with the latest policies of the American Medical Association. . . . It is expected that the new program will receive the approval of all interested parties . . ."

On December 18, 1957, Air Force representatives met with a group of Bexar County Medical Society members and presented a comprehensive industrial medicine program based on their interpretations of the A. M. A. policies. At the request of the Air Force representatives, society members examined this program and suggested changes in wording to clarify its scope and purpose. The introductory remarks to the program stated that the "Geriatric Program," upon which Bexar County Medical Society complaints were based, would be discontinued.

On February 11, 1958, the Executive Board of the Bexar County Medical Society voted to approve the principles outlined in the "Revision of the Physical Examination Program for Civilian Employees of Kelly Air Force Base." The Geriatrics Program has been discontinued and there have been no further reports of abuses of this program.

WORKMEN'S COMPENSATION AND INSURANCE CASES IN VA

There has been no further change in policy by the Veterans' Administration since the inauguration of the new procedure (reported in the 1957 Annual Report) whereby veterans whose care is covered by workmen's compensation will be so informed, and urged to review their statements of inability to pay and to request transfer to non-VA hospitals.

This procedure was announced to VA facilities in a directive dated May 29, 1957; it was announced to the public in a press release, dated June 26, 1957, which also noted that files sent to the VA central office for review may be referred to the Department of Justice, which may prosecute.

This directive has, therefore, been in effect over a year. No reports have yet been published by the Veterans' Administration, to the Committee's knowledge, evaluating the effectiveness of this directive. It has been noted that there was probably some decrease in compensation and insurance payments for VA patients in fiscal year 1957 from fiscal year 1956, since the 1956 report stated the VA received reimbursements of $4.8 million from non-Federal sources, the major portion consisting of "proceeds from hospitalization insurance contracts", while the 1957 report states merely "The VA medical program was credited with $7 million in appropriation reimbursements, approximately one-half of which were derived from Federal sources."

The Committee has requested from the Veterans Administration information as to the effect of this directive on its workmen's compensation case load during the 1958 fiscal year, and will report to the Association when this information is received.

The Committee noted in its 1957 report that it felt that private health insurance coverage in relation to VA medical care was a more difficult problem and should be held in abeyance while workmen's compensation was being discussed. As this position was approved by the reference committee and the House of Delegates, the Committee is awaiting data from the Veterans' Administration concerning the results of its workmen's compensation directive before making further recommendations for action on the question of insurance coverage.

LEGISLATIVE DEVELOPMENTS

Perhaps the most important new development in the veterans' medical care problem is the publication of House Committee Print No. 222, dated June 26, 1958, for the use of the House Committee on Veterans' Affairs.

In answer to a letter from Representative Olin E. Teague, Chairman of the Committee, requesting information as to the Administration's policy on the number of beds which would be maintained in the Veterans' Administration hospital system, the President released the text of a report based on joint studies by the Veterans' Administration, the Public Health Service, and the American Hospital Association. Included in this study is a report on the total number of veterans hospitalized as of June, 1957, by eligibility status, type of disability or disease, age, and auspices (VA or non-VA patient), as well as a projection of the estimated veteran patient load, service-connected and non-service-connected, by type of disability, through 1986.

Because these data so clearly illustrate the need for reappraisal of the VA hospital program, the Committee wishes to repeat some of them in this report. The combined studies indicated that a total of 187,800 male veterans were hospitalized in all public and private hospitals of the United States and Puerto Rico as of June, 1957 and that 110,200 of these were hospitalized under VA auspices. Nearly 3 out of every 5 veterans who needed hospital care received it from the VA. Over two-thirds of all tuberculous and psychiatric veteran patients received care from the VA, and close to half of the general medical, surgical, and neurological patients.

Of the 187,800 veteran patients, only 39,000 were being treated for service-connected conditions; the remaining 148,800 were all non-service-connected. About 48% of all non-service-connected conditions were treated in VA hospitals—60% of the NSC tuberculous load, 48.5% of the psychiatric load, and 45% of the general medical, surgical, and neurological load. About half the veteran patients, therefore, had stated they were unable to pay for care.

Projections from this study indicate that, by 1986, the service-connected load will decrease to 23,600, of which 22,000 will be psychiatric cases, while the total non-service-connected veteran patient load will increase from 148,800 to 304,500. In 1986, it is estimated, there will be 1,300 service-connected GMS&N cases, and 189,600 non-service-connected in this category.

The Committee believes that these figures bear out the medical profession's belief that there will be increasing pressure for more VA hospital beds in the future and that, even without any increase in beds, the care of service-connected cases will be a continually declining part of the Veterans' Administration's medical program unless its admission policies are changed and the program curtailed.

The House Committee on Veterans Affairs scheduled hearings on this subject for July, 1958, at which Dr. Russell B. Roth, chairman of the Committee on Federal Medical Services, testified for the American Medical Association.

COMMITTEE PUBLICATIONS

The Committee has published a brochure, entitled "Veterans and Non-Veterans: Two Classes of Citizens?" comprising a letter disagreeing with the medical profession's policy and a reply by Dr. Louis M. Orr, then chairman of the Committee, which first appeared in THE JOURNAL of the A. M. A., June 1, 1957, pages 572-579; copies have been distributed to all state veterans' affairs committees and to others concerned with the problems of veterans' medical care.

During the period from July, 1957 to June, 1958, the Committee published six issues of the Federal Medical Services Newsletter. In addition to articles on various aspects of veterans' medical care, Newsletter topics have included United States participation in international health programs, quality of care in Public Health Service hospitals, Indian health, health insurance for federal employees and in the Panama Canal Zone, and public assistance medical care. Publication in the May and June, 1958 Newsletters of a special report on the cost per case of care in VA and non-federal hospitals has already brought in a number of requests for copies from individuals and organizations not on the regular mailing list, which now includes some 4,900 names.

The Committee is preparing for publication an addendum to its March, 1957, factbook, "A. M. A. Policy on Medical Care of Veterans", to bring the statistical data in this brochure up to date, according to latest information available on VA operations. The Committee is also planning on publishing several brief leaflets, each concentrating on one facet of the relationship between veterans' medical care and the health of the nation as a whole.

FUTURE ACTIVITIES

The Committee is continuing to implement its directives from the House of Delegates to inform physicians and, when feasible, the public concerning the medical profession's policy on federal care for veterans and other federal non-military medical programs through its studies and reports in the Federal Medical Services Newsletter and other publications, all of which have been circulated widely inside and outside the medical profession.

These directives will be further implemented by the projected conference on veterans' medical care, at which the Committee expects both to assist the states in their activities through the interchange of opinion and experience among the representatives of the various areas and also to obtain recommendations from the state associations as to ways in which the Committee may intensify its own activities at the national level.

Committee on Indigent Care

There have been no changes in the membership of this committee during the past year. Current members are Drs. John F. Burton, Oklahoma City, Chairman; A. J. Bowles, Seattle; I. Jay Brightman, Albany, New York; E. P. Coleman, Canton, Illinois; Wesley W. Hall, Reno, Nevada; E. A. Ockuly, Toledo, Ohio; Dean W. Roberts, Chicago; and J. D. McCarthy, Omaha, ex officio. Committee consultants are Mr. R. M. Hilliard, Chicago, and Mr. Nelson B. Neff, Reno, Nevada. Staff includes Mr. George W. Cooley, Secretary, and Mr. James H. Fleming and Mr. Nicholas M. Griffin, Research Assistants.

COMMITTEE MEETINGS

The Committee held two meetings in Chicago during the year; on October 20-21, 1957 and on March 15-16, 1958. At each meeting, one day was devoted to a conference with representatives of state medical associations which were having problems in the field of indigent medical care. At the October meeting, representatives were present from eleven state associations and, at the March meeting, from twelve state associations.

Representatives of the Federal Bureau of Public Assistance of the Department of Health, Education, and Welfare were present at both sessions to discuss these problems and to provide information on the current public assistance situation. A representative of the American Public Welfare Association was also present at both conferences, to present the viewpoint of the professional welfare worker.

The Committee feels that these conferences have been most helpful to Committee members, in that they have obtained firsthand information as to the problems which most concern the medical societies in each state in regard to the provision of indigent medical care. State association representatives have also expressed the opinion that the conferences helped them to gain a broader perspective of the over-all problems and policies involved than would be possible without this contact with other state association representatives.

STAFF TRAVEL

Prior to the March, 1958, meeting, Mr. Nelson B. Neff, in his capacity as Committee consultant, conferred with various officers and members of the California Medical Association preparatory to reporting to the Committee on the controversy which arose in reference to the new California indigent care program. In October, 1957, at the request of the State Medical Society of Wisconsin, a member of the Council's Research staff, met at Madison, Wisconsin, with representatives of the state medical association and the state welfare department to discuss the effect of new Social Security amendments on the Wisconsin medical care plan.

On June 9-13, 1958, a member of the staff attended a meeting on Organized Home Care at Roanoke, Virginia, sponsored by the U. S. Public Health Service. The meeting was attended by 23 persons representing a number of national organizations in the health field and fifteen different home care programs throughout the country. The conference had as its objectives the determination of the place of home care programs in the care of the chronically ill, the community resources and attitudes necessary for such programs, guide-lines to help communities implement these programs, and areas where further research is necessary. Dr. I. Jay Brightman, a member of the Committee on Indigent Care, was also present at this conference.

ENDORSEMENT OF VENDOR PAYMENTS

At the Philadelphia session of the House of Delegates (December, 1957), Dr. Lawrence R. Dame, representing the Massachusetts Medical Society, introduced Resolution No. 18, "Endorsement of the Vendor System of Payment." The substance of this resolution was that the House of Delegates should endorse the direct or vendor system of payment to physicians for professional services rendered to public assistance patients. The resolution was referred to the Council on Medical Service, which transmitted it to the Committee on Indigent Care for study and recommendations.

At its March, 1958, conference with state association representatives including Dr. Dame as the Massachusetts representative, the Committee discussed this resolution and the methods of payment now in effect in the various states. It became apparent at this meeting that there are widely divergent viewpoints in the various states as to the use of "vendor payments" to physicians, recommended by the resolution.

As examples of the differing viewpoints expressed, in addition to the Massachusetts position stated in the resolution, the Committee found that the Tennessee physicians opposed any payment to the physician from public funds for care of the indigent but supported vendor payments to hospitals provided that all indigent care was under the responsibility of the state health department. California physicians felt that any vendor payment for physicians' services to the indigent from public funds was socialized medicine. The Missouri association was conducting a referendum of its members to determine whether it should oppose vendor payment entirely, or for physicians only, or take no definite stand until enabling legislation for such a program was introduced in the state legislature.

In the light of these varying opinions, the Committee felt that it should consider the possibility of alternative action which would achieve the same purpose as the proposed resolution.

In December, 1956, the House of Delegates had adopted a set of "Guides for Medical Societies in Developing Plans for Tax-Supported Personal Health Services for the Needy", which stated that "The methods of financing of such health services should be determined by the appropriate unit of government, local or state. Methods and amounts of payment for personal health services should be equitable and determined in conference between the responsible public agency and representatives of the providers."

This principle affirms that it should be the prerogative of the responsible state agency in each state, in consultation with the appropriate professional organizations within that state, rather than of the federal government, to decide what portion of the public assistance funds should be paid directly to providers of medical services and what portion to the assistance recipients themselves. The present Social Security Act effectively limits the exercise of this prerogative.

The Committee and the Council therefore recommended that the House of Delegates reaffirm the principle adopted in December, 1956, the prerogative of the states to determine the allocation and method of payment of these funds, and that it endorse in principle legislation which would return this right to the individual states.

This recommendation was approved by the House of Delegates at its June 1958 session at San Francisco, and the Council has so notified the Committee on Legislation.

1958 RESOLUTIONS

At the San Francisco session (June, 1958), Resolution No. 4, Indigent Care, introduced by the Utah State Medical Association, pointed out the current confusion in the medical care programs for welfare recipients and recommended that the Association bring this situation to the attention of Congress. The resolution further recommended (as revised by the reference committee) "that the American Medical Association request that any funds provided under the Public Assistance provisions of the Social Security Act for medical care of the indigent be administered by a voluntary agency such as Blue Shield on a cost plus basis or by a specific agency established by the medical society of the state in which indigent care is rendered." It was further resolved that this resolution be forwarded to the Committee on Indigent Care. The reference committee report was adopted by the House.

The Committee plans to study the implications of this resolution and will report to the House on the changes it will necessitate in national legislation, state plans, and the "Guides" adopted by the House in December, 1956.

CURRENT LEGISLATION

By June 30, 1958, Congress had not enacted any amendments to the Social Security Act which would significantly affect the provision of medical care to the indigent. A number of bills had been introduced, however, which would change these programs, among them bills which would give the states complete leeway as to the allocation of vendor payment funds and payments to assistance recipients within the limits of federally matched expenditures as well as bills which would establish a new program of Federal participation in general assistance costs. General assistance, at present, is provided solely from state and local funds, for those not eligible for the four Federally aided programs; the new bill would include Federal participation in all assistance to the needy, not merely to the aged, dependent children, the blind, and the disabled.

Representatives of the Federal Bureau of Public Assistance of the Department of Health, Education, and Welfare were present at both sessions to discuss these problems and to provide information on the current public assistance situation. A representative of the American Public Welfare Association was also present at both conferences, to present the viewpoint of the professional welfare worker.

The Committee feels that these conferences have been most helpful to Committee members, in that they have obtained firsthand information as to the problems which most concern the medical societies in each state in regard to the provision of indigent medical care. State association representatives have also expressed the opinion that the conferences helped them to gain a broader perspective of the over-all problems and policies involved than would be possible without this contact with other state association representatives.

STAFF TRAVEL

Prior to the March, 1958, meeting, Mr. Nelson B. Neff, in his capacity as Committee consultant, conferred with various officers and members of the California Medical Association preparatory to reporting to the Committee on the controversy which arose in reference to the new California indigent care program. In October, 1957, at the request of the State Medical Society of Wisconsin, a member of the Council's Research staff, met at Madison, Wisconsin, with representatives of the state medical association and the state welfare department to discuss the effect of new Social Security amendments on the Wisconsin medical care plan.

On June 9-13, 1958, a member of the staff attended a meeting on Organized Home Care at Roanoke, Virginia, sponsored by the U. S. Public Health Service. The meeting was attended by 23 persons representing a number of national organizations in the health field and fifteen different home care programs throughout the country. The conference had as its objectives the determination of the place of home care programs in the care of the chronically ill, the community resources and attitudes necessary for such programs, guide-lines to help communities implement these programs, and areas where further research is necessary. Dr. I. Jay Brightman, a member of the Committee on Indigent Care, was also present at this conference.

ENDORSEMENT OF VENDOR PAYMENTS

At the Philadelphia session of the House of Delegates (December, 1957), Dr. Lawrence R. Dame, representing the Massachusetts Medical Society, introduced Resolution No. 18, "Endorsement of the Vendor System of Payment." The substance of this resolution was that the House of Delegates should endorse the direct or vendor system of payment to physicians for professional services rendered to public assistance patients. The resolution was referred to the Council on Medical Service, which transmitted it to the Committee on Indigent Care for study and recommendations.

At its March, 1958, conference with state association representatives including Dr. Dame as the Massachusetts representative, the Committee discussed this resolution and the methods of payment now in effect in the various states. It became apparent at this meeting that there are widely divergent viewpoints in the various states as to the use of "vendor payments" to physicians, recommended by the resolution.

As examples of the differing viewpoints expressed, in addition to the Massachusetts position stated in the resolution, the Committee found that the Tennessee physicians opposed any payment to the physician from public funds for care of the indigent but supported vendor payments to hospitals provided that all indigent care was under the responsibility of the state health department. California physicians felt that any vendor payment for physicians' services to the indigent from public funds was socialized medicine. The Missouri association was conducting a referendum of its members to determine whether it should oppose vendor payment entirely, or for physicians only, or take no definite stand until enabling legislation for such a program was introduced in the state legislature.

In the light of these varying opinions, the Committee felt that it should consider the possibility of alternative action which would achieve the same purpose as the proposed resolution.

In December, 1956, the House of Delegates had adopted a set of "Guides for Medical Societies in Developing Plans for Tax-Supported Personal Health Services for the Needy", which stated that "The methods of financing of such health services should be determined by the appropriate unit of government, local or state. Methods and amounts of payment for personal health services should be equitable and determined in conference between the responsible public agency and representatives of the providers."

This principle affirms that it should be the prerogative of the responsible state agency in each state, in consultation with the appropriate professional organizations within that state, rather than of the federal government, to decide what portion of the public assistance funds should be paid directly to providers of medical services and what portion to the assistance recipients themselves. The present Social Security Act effectively limits the exercise of this prerogative.

The Committee and the Council therefore recommended that the House of Delegates reaffirm the principle adopted in December, 1956, the prerogative of the states to determine the allocation and method of payment of these funds, and that it endorse in principle legislation which would return this right to the individual states.

This recommendation was approved by the House of Delegates at its June 1958 session at San Francisco, and the Council has so notified the Committee on Legislation.

1958 RESOLUTIONS

At the San Francisco session (June, 1958), Resolution No. 4, Indigent Care, introduced by the Utah State Medical Association, pointed out the current confusion in the medical care programs for welfare recipients and recommended that the Association bring this situation to the attention of Congress. The resolution further recommended (as revised by the reference committee) "that the American Medical Association request that any funds provided under the Public Assistance provisions of the Social Security Act for medical care of the indigent be administered by a voluntary agency such as Blue Shield on a cost plus basis or by a specific agency established by the medical society of the state in which indigent care is rendered." It was further resolved that this resolution be forwarded to the Committee on Indigent Care. The reference committee report was adopted by the House.

The Committee plans to study the implications of this resolution and will report to the House on the changes it will necessitate in national legislation, state plans, and the "Guides" adopted by the House in December, 1956.

CURRENT LEGISLATION

By June 30, 1958, Congress had not enacted any amendments to the Social Security Act which would significantly affect the provision of medical care to the indigent. A number of bills had been introduced, however, which would change these programs, among them bills which would give the states complete leeway as to the allocation of vendor payment funds and payments to assistance recipients within the limits of federally matched expenditures as well as bills which would establish a new program of Federal participation in general assistance costs. General assistance, at present, is provided solely from state and local funds, for those not eligible for the four Federally aided programs; the new bill would include Federal participation in all assistance to the needy, not merely to the aged, dependent children, the blind, and the disabled.

If any of these bills should be enacted by Congress during this session and are of sufficient importance in the area of indigent medical care, essential information will be presented to the House of Delegates in a supplementary report.

COST OF "MEDICAL" CARE

The Committee has noted with concern a tendency on the part of the public to consider the medical profession responsible for all the costs of medical services to indigent patients, despite the fact that "medical services", in the context of public and general assistance programs, includes all auxiliary health services and facilities, such as hospitals, nursing homes, drugs, therapy, and, in some states, dental care. It therefore feels that this report should include data released by the Bureau of Public Assistance on vendor payments for medical care during the 1957 calendar year, in a report dated July, 1958.

According to this release, the total expenditures for public and general assistance during the year amounted to about $3.1 billion, of which $2.8 billion was expended for public assistance recipients and about $0.3 billion for general assistance recipients (state and local funds only). Of this amount, $302 million (about 10%) was allocated to vendor payments for medical care. This includes only payments made by the disbursing agency directly to the providers of such care, since no accurate check can be made of payments made to physicians, hospitals, and others by the assistance recipients themselves.

Of the $302 million for vendor payments, $287 million was actually paid out to providers of care and some $15 million remained in pooled funds at the end of the year; $211 million was expended for public assistance recipients and $76 million for general assistance patients.

The states did not report to the Bureau of Public Assistance on the type of service purchased by $62 million of this money—but of the $225 million which was reported by type of service, only $21.7 million went to "practitioners"; $110 million went to hospitals, $44 million to nursing and convalescent homes, $21.3 million for drugs and supplies, and $27 million for other services, including dental and nursing services and prosthesis.

From these figures, it is apparent that physicians' services comprise less than ten per cent of the cost of vendor medical payments. This is generally true in all assistance programs, except aid to dependent children, where physicians' services comprise about a fourth of the cost and nursing home care is minimal.

FUTURE ACTIVITIES

The Committee plans to gear its future activities to the needs of the various states, providing them with necessary information on laws and existing programs, advice, and consultation when requested. It is planning several more meetings during 1958, on the pattern of the past two meetings, at which state association representatives from a given area will be given an opportunity to gather at a central location and compare, and possibly work out their problems together, with the assistance of the Committee members and of representatives of the federal bureau.

The Committee believes that the medical profession should guide the development and operation of the medical aspects of these programs, to assure their remaining within proper bounds. One step which might assist in attaining this goal is the establishment of more adequate liaison between the medical profession and the welfare officials within the states; the Committee is studying ways in which this liaison might be improved.

In its 1957 report, the Committee recommended that the House of Delegates urge state medical associations and county medical societies to take an active part in the planning and operation of indigent medical care programs. The Committee has been informed by a number of state associations of the active part they have taken, not only in planning such programs, but even in stimulating legislatures and government officials to undertake the study of state needs and facilities, preparatory to such programs.

The Committee feels, however, that it should reiterate the need for continued active interest not only at the state, but at the county level, in medical care for both those assistance recipients included in the federally-aided programs and for those provided for from local funds only. The Committee feels that there will be a continually increasing interest in medical services in welfare programs; this interest is already evident at the national level, and is growing in the states and counties. As the Committee stated in its last report, "it behooves medicine to work with welfare agencies to see to it that proper and adequate programs are developed."

The Committee wishes to point out, in addition, that this recommendation does not apply only to those areas where the medical profession receives payment from public funds for its care of the indigent. Even when physicians' services are provided through the charity of the individual physician in his office or while he is on staff service at the local hospital, the medical society should still maintain an active interest in the goals, the methods, and the operations of the over-all medical care program for the good of the patient and to assure the proper control of this total welfare service.

COMMITTEE PUBLICATIONS

Public Assistance.—The Committee's 1957 annual report noted the publication of "Medical Care for the Indigent in 1957", a series of 52 questions and answers on public assistance medical care, with particular reference to the effect of the 1956 amendments to the public assistance titles of the Social Security Act. This Committee brochure, which gives history and background on public assistance programs as well as recent devcopments, has been widely distributed both to medical societies and to other individuals and organizations interested in welfare programs.

On October 21, 1957, the Committee published its "Supplementary Report No. 1: Medical Care for the Indigent in 1957." The material in this report brought the earlier study up to date in the light of Public Law 85-110, passed in July, 1957, which further amended the legislation governing federal participation in state indigent medical care programs.

The 1956 and 1957 amendments raised a number of problems for the various states; a certain amount of confusion was caused by the Bureau of Public Assistance's prohibition of "split payments" for medical services. This term applies to a payment method in which part of the cost of a given service was paid directly to the provider of such services and the remainder of the cost was to be paid by the individual assistance recipient.

The Committee therefore published, in the May 17, 1958, issue of The Journal of the A. M. A., a "Supplementary Report No. 2: Medical Care for the Indigent in 1957." This report was concerned primarily with difficulties which had arisen in state indigent medical care plans, with particular reference to "split payments" and the reasons for Bureau of Public Assistance policy.

The federal agency has been given an opportunity to examine and make recommendations in regard to each of these reports prior to publication, in order that the final version may be as clear and as accurate as possible.

The first report and the two supplementary reports are available in pamphlet form from the Council on Medical Service. Copies have been distributed to state medical associations, and many requests have been filled from organizations outside the medical profession.

Organized Home Care Study.—In the early part of 1957, the Committee published a report on its study of "organized 'Home Care' Programs in the United States". This report has appeared both in brochure form and The Journal of the A. M. A.; a summary of the study was also published in the August, 1957, issue of the Chronic Illness Newsletter.

The study reported on 31 different programs through which patients who do not require the full range of hospital services are provided with individualized medical, nursing, social, and rehabilitation services in their own homes, coordinated through a central agency. Approximately 1,500 copies of this report have been distributed. Mailings were made to state and territorial medical associations and to local medical societies in the areas where home care programs are operating. The majority of the copies, however, has been mailed on an individual request basis. The study has been used as source material at several conferences on the subject.

Since this study was published, material has been gathered on additional programs recently established. The report is at present being revised to include these new programs.

Central Information and Referral Services.—For several years the Committee has been gathering data on central information and referral services for the chronically ill. These, as the name implies, are agencies intended to assemble, study, and make available information on existing community facilities and resources for the chronically ill, with the additional possibility of determining unmet needs, developing coordinated community programs, and assisting individual organizations in planning facilities and programs for the chronically ill. The Committee is at present aware of five such services, operating in Chicago, Milwaukee, Cleveland, San Francisco, and Essex County, New Jersey. A report on these centers, covering their history, administration, operation, services provided, and other pertinent data is being compiled. The Committee expects to publish this report in the fall of 1958.

Committee on Maternal and Child Care

The members of this Committee are: Drs. W. L. Crawford, Chairman, Rockford, Illinois; R. B. Chrisman, Jr., Coral Gables, Florida; Philip S. Barba, Philadelphia, Pennsylvania; Harold S. Morgan, Lincoln, Nebraska; Garland D. Murphy, El Dorado, Arkansas; Howard A. Nelson, Greenwood, Mississippi; J. L. Reichert, Chicago, Illinois; and J. D. McCarthy, Omaha, ex officio. Committee consultants are: Drs. Donald A. Dukelow, Chicago, Illinois, and Philip F. Wiliams, Philadelphia, Pennsylvania, and Mr. Edwin J. Holman, Chicago, Illinois. Staff members are: Mr. George W. Cooley, Secretary, and Mr. Donald B. Berg, Research Assistant.

MEETINGS

The Committee sponsored its first regional meeting on perinatal mortality and morbidity problems in Philadelphia on December 2, 1957 (the day prior to the Clinical Session). The invited participants to this regional conference were physicians active in perinatal study and research representing state and local medical societies, specialty groups, state and local public health departments, and hospitals and medical centers from 14 northeastern states of the United States. A total of 89 physicians (exclusive of Committee members) attended including representatives of the National Office of Vital Statistics and the Children's Bureau.

The purpose of this meeting was to review and analyze some of the current efforts in the study of perinatal mortality and morbidity; to discuss problems encountered in these efforts; to explore ways and means for improving these efforts; to work toward more uniformity in terminology and classification; and to help establish principles on which sound medical policies can be based for the promotion of programs designed to reduce perinatal mortality and morbidity. The meeting was mutually beneficial—the participants expressing appreciation for the knowledge gained in sharing experiences with the group, and in turn the Committee gained information and the consensus of the group useful for its proposed compilation of recommendations for a flexible basic program to be used by state, city-county, or hospital committees in the study of perinatal mortality and morbidity.

The Committee next met in Chicago on March 22, 1958 and conducted its second regional conference on perinatal mortality and morbidity problems on March 23. This meeting encompassed representatives working on and interested in these problems from 13 north-central states. In addition to the Committee members, seventy-three highly qualified participants attended. Main topics of discussion were: Preventive factors in the reduction of perinatal mortality and morbidity, terms and definitions, organization and operation of studies, and classification of causes of perinatal mortality. Again, as at the first regional meeting, informal votes of expression and choice were taken on many of these items to aid the Committee in its proposed recommendations.

At the conclusion of this second regional meeting, the Committee decided that before sponsoring further regional conferences, it would be more appropriate to meet in joint session with representatives of interested national organizations and agencies in order that the proposed guide might be developed as quickly as possible. The Committee, therefore, scheduled this joint conference for July 26-27, 1958.

PERINATAL STUDY PROJECT

The field work reported in last year's annual report continued from June into July with visits to Seattle, Washington; Portland and Eugene, Oregon; and several points in Montana (state-wide program). This work continued with later visits to review the programs in Delaware; Connecticut; Baltimore, Maryland; and Columbus, Ohio. A special conference to consider these problems was attended by staff in New York City in October. This conference was sponsored by the New York Academy of Medicine, the Departments of Health and Hospitals of the city of New York, and other interested local groups. Information and consensus on several matters obtained from this conference were made available to the Committee for use in its deliberations and are incorporated in the New York article which will appear as one part of a series to be published. (See Articles and Publications.) The experience in Saginaw, Michigan was reviewed during a field study early in 1958, and a pertinent activity in Illinois, and Second Illinois Congress on Maternal and Child Health sponsored by the Illinois Committee on Maternal Welfare, was attended by staff.

ARTICLES AND PUBLICATIONS

The Committee's publications on perinatal mortality and morbidity started with an editorial in THE JOURNAL, June 21, 1958. This editorial referred to and summarized briefly the three articles appearing in the same issue—Challenge of Fetal Loss, Prematurity, and Infant Mortality—Assessing the Local Situation, by Leona Baumgartner, M.D. and Jean Pakter, M.D., New York; Deaths Around Births—The National Score, by Martha M. Eliot, M.D., Washington, D. C.; Challenge of Fetal Loss, Prematurity, and Infant Mortality—a World View, by Louis J. Verhoestraete, M.D., and Ruth R. Puffer, Dr. P.H., Washington, D. C. The editorial also outlined briefly the Committee's work in this field and its program to stimulate interest in and disseminate information on these problems of the perinatal period. The June 28, 1958 issue of THE JOURNAL contained Part 1 of the Committee's series on "Study of Perinatal Mortality and Morbidity Programs in the United States." An editorial introducing this series also appeared in the June 28 JOURNAL. Four more articles are scheduled to be published in July and August and an additional seven articles in this series are in various stages of completion and will appear in THE JOURNAL from time to time this fall and winter.

EXHIBIT

The Committee developed an exhibit entitled "Perinatal Mortality and Morbidity". This was first exhibited at the Illinois State Medical Society's annual meeting in Chicago in May. It was then presented in the scientific exhibit section at the A. M. A.'s San Francisco meeting in June. The exhibit was designed to define and describe the extent of the problem, to show the relative lag in mortality decrease in the early infant and perinatal period, and to indicate what is currently being done in the United States, what the Committee on Maternal and Child Care is doing, and what some of the Committee plans are relative to this problem. The material contained on the exhibit was reproduced in leaflet form for distribution at the booth. Nearly 1,000 such leaflets were distributed along with hundreds of copies of other summary outlines, and descriptive and statistical papers and booklets. There seemed to be an enthusiastic response and a great deal of interest in this material.

FUTURE ACTIVITIES AND PUBLICATIONS

With the above-mentioned study of various well organized perinatal mortality study programs, the regional and joint meetings, and a proposed meeting in October with such agencies as the Children's Bureau, the National Office of Vital Statistics, sections of the National Institutes of Health, and others, it is anticipated that the Committee's work on the proposed "Guide for Study of Perinatal Mortality and Morbidity" will be ready for Council review and approval in time for submission to the House of Delegates in December.

The Committee has given priority to the above work on perinatal mortality and morbidity because the need was urgent. It plans, further, to hold regional meetings in various parts of the country after the "guide" booklet is published. These will be informational and instructive meetings designed to help those medical societies desiring to organize committees and programs of study in this field. Other means, such as the production of a motion picture film for strengthening the Committee's informational and educational effectiveness are in the exploratory stage.

Other aspects of maternal and child care are receiving serious thought and consideration by the Committee. Problems relating to medical society organization and leadership in the many facets of preventive measures and health care for mothers and infants are to be given close attention, and after more study, specific recommendations will be forthcoming.

Other problems such as those relating to immunization, maternity and nursery staphylococcic infections and their prevention, and other current clinical and service areas are under consideration for more concerted study and research.

Committee on Medical Care for Industrial Workers

The members of this Committee are: Drs. Frank J. Holroyd†, Chairman, Princeton, West Virginia; T. J. Danaher†, Torrington, Connecticut; Edwin P. Jordan†, Charlottesville, Virginia; Melvin N. Newquist*, New York; Leo Price*, New York; William A. Sawyer*, Rochester, New York; Frederick W. Slobe*, Chicago; and Clyde C. Sparks†, Ashland, Kentucky. Consultants are Drs. Donald A. Dukelow and Arthur N. Springall. Members of the Committee staff are Dr. B. Dixon Holland, Secretary, Council on Industrial Health; Mr. George W. Cooley, Secretary, Council on Medical Service, and Mr. Murray Klutch, Research Associate. († = appointed by Council on Medical Service, * = appointed by Board of Trustees upon recommendation of Council on Industrial Health.)

UMWA WELFARE AND RETIREMENT FUND

One of the major areas of activity of the Committee during the past year, as in previous years, was that concerned with the relationships between the medical profession and the United Mine Workers of America Welfare and Retirement Fund. In its last Annual Report the Committee registered its disappointment over the rejection by the Executive Medical Officer of the Fund of the "Suggested Guides to Relationships Between State and County Medical Societies and the United Mine Workers of America Welfare and Retirement Fund", which had been adopted by the House of Delegates at the 1957 Annual session. This refusal to accept the Guides led to discussions among several state and numerous county medical societies as to how to deal further with the Fund. Various actions were undertaken in the way of letters, meetings, resolutions, and conferences with Area Medical Administrators—with individual societies attempting to meet their particular problems in a manner each considered most advisable and expedient.

There was evident a lack of general agreement among physicians as to how to react to the Fund's rejection of the Guides. The adoption of the Guides by the House of Delegates had implied to most physicians a recognition by the states of their responsibilities to render good medical care to beneficiaries of the Fund and to adhere to the appeal mechanism outlined in these Guides. The refusal of the Executive Medical Officer of the Fund was based primarily on his rejection of the statement in the Guides that "Every physician duly licensed by the state to practice medicine and surgery should be assumed at the outset to be competent in the field in which he claims to be, unless considered otherwise by his peers." The Executive Medical Officer of the Fund maintained further that the profession was unable to discipline its own members and that such a statement would have no effect on the attitude of medical societies. The situation had therefore evolved into one in which some physicians were continuing to serve beneficiaries of the Fund and are reimbursed directly by the Fund; other physicians were continuing to serve beneficiaries of the Fund and billing the patient but are not being reimbursed by the Fund; and still other physicians formerly rendering service are apparently not caring for Fund patients at all.

On September 10, 1957 the Executive Medical Officer of the Fund sent a communication to his Area Medical Administrators further restricting the number of physicians and hospitals to serve miners and their families. The contents of this memorandum and the effect of its application started a chain reaction which is still underway. Beginning October 1, Area Medical Administrators started notifying some of the 6,800 physicians, already approved by the Fund to render medical and surgical services to beneficiaries, that their services would be terminated on or after October 15, 1957. The basis for the termination of these services was the following excerpt contained in the memorandum of the Executive Medical Officer:

> "To meet the mandatory requirement of conserving trust fund resources, and providing authorized services to beneficiaries, trust fund payments are hereby restricted to physicians and hospitals whose services are deemed necessary and essential."

It should be noted, however, that in the letter sent to physicians removed by Area Medical Administrators, the former were advised, "Please be assured no criticism of you is implied by this action; your services to fund beneficiaries have been appreciated."

For a number of weeks following this directive, it was impossible to ascertain exactly how many physicians or hospitals were affected by this directive. It was later learned, however, that the original group of 6,800 physicians had been reduced to some 5,000. The number of hospitals taken off the approved list has still not been revealed by the Fund.

The wave of protest against this action of the Fund, the heated debates, and various newspaper and magazine accounts, reflected in some measure the dissatisfaction of the profession with the action of the Fund in limiting even further the right of miners and their families to choose their physicians. Not all of the criticism against the UMWA came from physicians; miners themselves voiced protests publicly and staged a parade in at least one city in Ohio, decrying this action of the medical program of their union. In another state (Kentucky) a card-carrying member of the UMWA co-sponsored a bill which would have provided free choice of physicians. (This bill was subsequently defeated.)

The study reported on 31 different programs through which patients who do not require the full range of hospital services are provided with individualized medical, nursing, social, and rehabilitation services in their own homes, coordinated through a central agency. Approximately 1,500 copies of this report have been distributed. Mailings were made to state and territorial medical associations and to local medical societies in the areas where home care programs are operating. The majority of the copies, however, has been mailed on an individual request basis. The study has been used as source material at several conferences on the subject.

Since this study was published, material has been gathered on additional programs recently established. The report is at present being revised to include these new programs.

Central Information and Referral Services.—For several years the Committee has been gathering data on central information and referral services for the chronically ill. These, as the name implies, are agencies intended to assemble, study, and make available information on existing community facilities and resources for the chronically ill, with the additional possibility of determining unmet needs, developing coordinated community programs, and assisting individual organizations in planning facilities and programs for the chronically ill. The Committee is at present aware of five such services, operating in Chicago, Milwaukee, Cleveland, San Francisco, and Essex County, New Jersey. A report on these centers, covering their history, administration, operation, services provided, and other pertinent data is being compiled. The Committee expects to publish this report in the fall of 1958.

Committee on Maternal and Child Care

The members of this Committee are: Drs. W. L. Crawford, Chairman, Rockford, Illinois; R. B. Chrisman, Jr., Coral Gables, Florida; Philip S. Barba, Philadelphia, Pennsylvania; Harold S. Morgan, Lincoln, Nebraska; Garland D. Murphy, El Dorado, Arkansas; Howard A. Nelson, Greenwood, Mississippi; J. L. Reichert, Chicago, Illinois; and J. D. McCarthy, Omaha, ex officio. Committee consultants are: Drs. Donald A. Dukelow, Chicago, Illinois, and Philip F. Wiliams, Philadelphia, Pennsylvania, and Mr. Edwin J. Holman, Chicago, Illinois. Staff members are: Mr. George W. Cooley, Secretary, and Mr. Donald B. Berg, Research Assistant.

MEETINGS

The Committee sponsored its first regional meeting on perinatal mortality and morbidity problems in Philadelphia on December 2, 1957 (the day prior to the Clinical Session). The invited participants to this regional conference were physicians active in perinatal study and research representing state and local medical societies, specialty groups, state and local public health departments, and hospitals and medical centers from 14 northeastern states of the United States. A total of 89 physicians (exclusive of Committee members) attended including representatives of the National Office of Vital Statistics and the Children's Bureau.

The purpose of this meeting was to review and analyze some of the current efforts in the study of perinatal mortality and morbidity; to discuss problems encountered in these efforts; to explore ways and means for improving these efforts; to work toward more uniformity in terminology and classification; and to help establish principles on which sound medical policies can be based for the promotion of programs designed to reduce perinatal mortality and morbidity. The meeting was mutually beneficial—the participants expressing appreciation for the knowledge gained in sharing experiences with the group, and in turn the Committee gained information and the consensus of the group useful for its proposed compilation of recommendations for a flexible basic program to be used by state, city-county, or hospital committees in the study of perinatal mortality and morbidity.

The Committee next met in Chicago on March 22, 1958 and conducted its second regional conference on perinatal mortality and morbidity problems on March 23. This meeting encompassed representatives working on and interested in these problems from 13 north-central states. In addition to the Committee members, seventy-three highly qualified participants attended. Main topics of discussion were: Preventive factors in the reduction of perinatal mortality and morbidity, terms and definitions, organization and operation of studies, and classification of causes of perinatal mortality. Again, as at the first regional meeting, informal votes of expression and choice were taken on many of these items to aid the Committee in its proposed recommendations.

At the conclusion of this second regional meeting, the Committee decided that before sponsoring further regional conferences, it would be more appropriate to meet in joint session with representatives of interested national organizations and agencies in order that the proposed guide might be developed as quickly as possible. The Committee, therefore, scheduled this joint conference for July 26-27, 1958.

PERINATAL STUDY PROJECT

The field work reported in last year's annual report continued from June into July with visits to Seattle, Washington; Portland and Eugene, Oregon; and several points in Montana (state-wide program). This work continued with later visits to review the programs in Delaware; Connecticut; Baltimore, Maryland; and Columbus, Ohio. A special conference to consider these problems was attended by staff in New York City in October. This conference was sponsored by the New York Academy of Medicine, the Departments of Health and Hospitals of the city of New York, and other interested local groups. Information and consensus on several matters obtained from this conference were made available to the Committee for use in its deliberations and are incorporated in the New York article which will appear as one part of a series to be published. (See Articles and Publications.) The experience in Saginaw, Michigan was reviewed during a field study early in 1958, and a pertinent activity in Illinois, and Second Illinois Congress on Maternal and Child Health sponsored by the Illinois Committee on Maternal Welfare, was attended by staff.

ARTICLES AND PUBLICATIONS

The Committee's publications on perinatal mortality and morbidity started with an editorial in The Journal, June 21, 1958. This editorial referred to and summarized briefly the three articles appearing in the same issue—Challenge of Fetal Loss, Prematurity, and Infant Mortality—Assessing the Local Situation, by Leona Baumgartner, M.D. and Jean Pakter, M.D., New York; Deaths Around Births—The National Score, by Martha M. Eliot, M.D., Washington, D. C.; Challenge of Fetal Loss, Prematurity, and Infant Mortality—a World View, by Louis J. Verhoestraete, M.D., and Ruth R. Puffer, Dr. P.H., Washington, D. C. The editorial also outlined briefly the Committee's work in this field and its program to stimulate interest in and disseminate information on these problems of the perinatal period. The June 28, 1958 issue of The Journal contained Part 1 of the Committee's series on "Study of Perinatal Mortality and Morbidity Programs in the United States." An editorial introducing this series also appeared in the June 28 Journal. Four more articles are scheduled to be published in July and August and an additional seven articles in this series are in various stages of completion and will appear in The Journal from time to time this fall and winter.

EXHIBIT

The Committee developed an exhibit entitled "Perinatal Mortality and Morbidity". This was first exhibited at the Illinois State Medical Society's annual meeting in Chicago in May. It was then presented in the scientific exhibit section at the A. M. A.'s San Francisco meeting in June. The exhibit was designed to define and describe the extent of the problem, to show the relative lag in mortality decrease in the early infant and perinatal period, and to indicate what is currently being done in the United States, what the Committee on Maternal and Child Care is doing, and what some of the Committee plans are relative to this problem. The material contained on the exhibit was reproduced in leaflet form for distribution at the booth. Nearly 1,000 such leaflets were distributed along with hundreds of copies of other summary outlines, and descriptive and statistical papers and booklets. There seemed to be an enthusiastic response and a great deal of interest in this material.

FUTURE ACTIVITIES AND PUBLICATIONS

With the above-mentioned study of various well organized perinatal mortality study programs, the regional and joint meetings, and a proposed meeting in October with such agencies as the Children's Bureau, the National Office of Vital Statistics, sections of the National Institutes of Health, and others, it is anticipated that the Committee's work on the proposed "Guide for Study of Perinatal Mortality and Morbidity" will be ready for Council review and approval in time for submission to the House of Delegates in December.

The Committee has given priority to the above work on perinatal mortality and morbidity because the need was urgent. It plans, further, to hold regional meetings in various parts of the country after the "guide" booklet is published. These will be informational and instructive meetings designed to help those medical societies desiring to organize committees and programs of study in this field. Other means, such as the production of a motion picture film for strengthening the Committee's informational and educational effectiveness are in the exploratory stage.

Other aspects of maternal and child care are receiving serious thought and consideration by the Committee. Problems relating to medical society organization and leadership in the many facets of preventive measures and health care for mothers and infants are to be given close attention, and after more study, specific recommendations will be forthcoming.

Other problems such as those relating to immunization, maternity and nursery staphylococcic infections and their prevention, and other current clinical and service areas are under consideration for more concerted study and research.

Committee on Medical Care for Industrial Workers

The members of this Committee are: Drs. Frank J. Holroyd†, Chairman, Princeton, West Virginia; T. J. Danaher†, Torrington, Connecticut; Edwin P. Jordan†, Charlottesville, Virginia; Melvin N. Newquist*, New York; Leo Price*, New York; William A. Sawyer*, Rochester, New York; Frederick W. Slobe*, Chicago; and Clyde C. Sparks†, Ashland, Kentucky. Consultants are Drs. Donald A. Dukelow and Arthur N. Springall. Members of the Committee staff are Dr. B. Dixon Holland, Secretary, Council on Industrial Health; Mr. George W. Cooley, Secretary, Council on Medical Service, and Mr. Murray Klutch, Research Associate. (†=appointed by Council on Medical Service, *=appointed by Board of Trustees upon recommendation of Council on Industrial Health.)

UMWA WELFARE AND RETIREMENT FUND

One of the major areas of activity of the Committee during the past year, as in previous years, was that concerned with the relationships between the medical profession and the United Mine Workers of America Welfare and Retirement Fund. In its last Annual Report the Committee registered its disappointment over the rejection by the Executive Medical Officer of the Fund of the "Suggested Guides to Relationships Between State and County Medical Societies and the United Mine Workers of America Welfare and Retirement Fund", which had been adopted by the House of Delegates at the 1957 Annual session. This refusal to accept the Guides led to discussions among several state and numerous county medical societies as to how to deal further with the Fund. Various actions were undertaken in the way of letters, meetings, resolutions, and conferences with Area Medical Administrators—with individual societies attempting to meet their particular problems in a manner each considered most advisable and expedient.

There was evident a lack of general agreement among physicians as to how to react to the Fund's rejection of the Guides. The adoption of the Guides by the House of Delegates had implied to most physicians a recognition by the states of their responsibilities to render good medical care to beneficiaries of the Fund and to adhere to the appeal mechanism outlined in these Guides. The refusal of the Executive Medical Officer of the Fund was based primarily on his rejection of the statement in the Guides that "Every physician duly licensed by the state to practice medicine and surgery should be assumed at the outset to be competent in the field in which he claims to be, unless considered otherwise by his peers." The Executive Medical Officer of the Fund maintained further that the profession was unable to discipline its own members and that such a statement would have no effect on the attitude of medical societies. The situation had therefore evolved into one in which some physicians were continuing to serve beneficiaries of the Fund and are reimbursed directly by the Fund; other physicians were continuing to serve beneficiaries of the Fund and billing the patient but are not being reimbursed by the Fund; and still other physicians formerly rendering service are apparently not caring for Fund patients at all.

On September 10, 1957 the Executive Medical Officer of the Fund sent a communication to his Area Medical Administrators further restricting the number of physicians and hospitals to serve miners and their families. The contents of this memorandum and the effect of its application started a chain reaction which is still underway. Beginning October 1, Area Medical Administrators started notifying some of the 6,800 physicians, already approved by the Fund to render medical and surgical services to beneficiaries, that their services would be terminated on or after October 15, 1957. The basis for the termination of these services was the following excerpt contained in the memorandum of the Executive Medical Officer:

> "To meet the mandatory requirement of conserving trust fund resources, and providing authorized services to beneficiaries, trust fund payments are hereby restricted to physicians and hospitals whose services are deemed necessary and essential."

It should be noted, however, that in the letter sent to physicians removed by Area Medical Administrators, the former were advised, "Please be assured no criticism of you is implied by this action; your services to fund beneficiaries have been appreciated."

For a number of weeks following this directive, it was impossible to ascertain exactly how many physicians or hospitals were affected by this directive. It was later learned, however, that the original group of 6,800 physicians had been reduced to some 5,000. The number of hospitals taken off the approved list has still not been revealed by the Fund.

The wave of protest against this action of the Fund, the heated debates, and various newspaper and magazine accounts, reflected in some measure the dissatisfaction of the profession with the action of the Fund in limiting even further the right of miners and their families to choose their physicians. Not all of the criticism against the UMWA came from physicians; miners themselves voiced protests publicly and staged a parade in at least one city in Ohio, decrying this action of the medical program of their union. In another state (Kentucky) a card-carrying member of the UMWA co-sponsored a bill which would have provided free choice of physicians. (This bill was subsequently defeated.)

At the 1957 Clinical Session, the House of Delegates adopted Resolution No. 20, submitted by Colorado and amended to read as follows:

Resolution No. 20—Relative to UMWA Welfare and Retirement Fund

Whereas, The United Mine Workers of America Welfare and Retirement Fund has disregarded the "Guides to Relationships Between State and County Medical Societies and the UMWA Welfare and Retirement Fund" which were adopted by this House of Delegates in New York in June, 1957; and

Whereas, The Medical Director of that Fund has publicly disavowed these adopted principles and has publicly stated that his organization will not observe them; and

Whereas, The Fund has, throughout the United States, arbitrarily further abrogated the right of the Fund's beneficiaries to a free choice of physicians and hospitals effective October 15, 1957; and

Whereas, These activities of the Fund appear to be a part of a broad general plan to reduce the practice of medicine to a state of servility, against the public interest; and

Whereas, All systems of medical care which deny patients their inalienable right to free choice of physician and hospital result in deterioration in the quality of medical care; therefore be it

Resolved, That this House of Delegates condemns the current attitude and method of operation of the U.M.W.A. Welfare and Retirement Fund as tending to lower the quality and availability of medical and hospital care to its beneficiaries; and be it further

Resolved, That a broad educational program be instituted at once by the American Medical Association to inform the general public, including the beneficiaries of the Fund, concerning the benefits to be derived from preservation of the American right to freedom of choice of physicians and hospitals as well as observance of the "Guides to Relationships Between State and County Medical Societies and the UMWA Welfare and Retirement Fund" adopted by this House last June.

At the same session the House of Delegates adopted Resolution No. 24, submitted by Pennsylvania, reading as follows:

Resolution No. 24—Conference with Third Parties

Whereas, There is an ever increasing number of third parties assuming the financial obligation of providing medical and surgical care for their respective beneficiaries; and

WHEREAS, This procedure has, in some instances, disturbed the normal physician-patient relationship and created other problems between the medical profession and third parties; and

WHEREAS, Several third parties have indicated their willingness to solve mutual problems through discussion and conference; therefore be it

Resolved, That the House of Delegates of the American Medical Association instruct the appropriate committee or council to engage in conferences with third parties to develop general principles and policies which may be applied to the relationship between third parties and members of the medical profession.

In an attempt to implement the intent of Resolution No. 20, the staffs of the Council on Medical Service and the Department of Public Relations prepared various materials and suggestions for approaches to comply with the action of the House. On March 10 a meeting was held by the staff with representatives from six states involved in the UMWA controversy in order to discuss the proposed educational campaign and to seek advice from the participants in the meeting with regard to the type of program and the nature of materials which they felt were necessary to be prepared. The meeting with the representatives from the states revealed not only a difference of opinion as to how to proceed, but pointed first to the need for an educational program among physicians themselves in order to acquaint them with the reasons for, and methods of, operation of all third-party programs, including that of the UMWA. It was the consensus at the meeting that the individual states would be the final judges of what material, and how much of the material, would be used, depending upon local factors and situations. Firm beliefs were also expressed to the effect that physicians themselves were divided in their thinking about an approach to the third-party problem, including UMWA. Opinions were also expressed to the effect that the American Medical Association lacked a clear-cut definition and policy with regard to "free choice of physician," and that a uniform approach to all third parties rather than to UMWA alone was necessary.

When the Committee met on March 22 and 23 to consider its course of action with regard to Resolution 20, as well as Resolution 24, it had before it numerous documents, reports, speeches, and articles by members of the medical profession as well as a summary of the meeting previously referred to. The Committee evolved the basis for the draft of a statement, which it later approved, and which was ultimately amended and approved by the Councils on Medical Service and Industrial Health and submitted to the Board of Trustees. This statement read as follows:

Resolution No. 20 was submitted to the Council on Medical Service and Council on Industrial Health with the suggestion that they ". . . meet to discuss and formulate a program to implement the action of the House and submit recommendations in this regard to the General Manager." Resolution No. 24 was submitted to the Council on Medical Service for its attention.

Since the Committee on Medical Care for Industrial Workers, a joint committee of the two Councils, normally reviews such matters, both resolutions were referred to that Committee for its consideration and recommendations. That Committee met on March 22-23 to consider both resolutions and made its report to both Councils. The report, as amended and approved by both Councils, is herewith submitted to the Board of Trustees.

The Committee on Medical Care for Industrial Workers has discussed at length Resolution No. 20, relative to the UMWA Welfare and Retirement Fund, introduced by the Colorado State Medical Society and adopted as amended by the House of Delegates in December, 1957. (Reproduced above.)

The Committee is in agreement that medicine's side of this controversy should be presented to the medical profession and subsequently to the public. It feels, however, that consideration should first be given to three aspects of the problem before such a campaign, if embarked upon, can be conducted successfully.

The first aspect concerns third parties in general. In December, 1957, the Pennsylvania delegation introduced Resolution No. 24 adopted by the House. (Reproduced above.)

It is the Committee's opinion that any campaign such as envisioned in the Colorado Resolution No. 20 should take into consideration all third parties as well as the one suggested in Resolution No. 24. The extent of the success of any broad public educational effort is contingent upon the broadest foundation of professional understanding of existing relationships and methods of operations of various types of plans. It is evident that all physicians are not aware of the various aspects of this problem. The Committee therefore considers that it may first be necessary to engage in a variety of efforts to acquaint all physicians, and for the medical profession to become accurately informed, before an educational program directed to the public is formulated.

It is the Committee's further belief that in the consideration of both resolutions the Rights and Responsibilities of patients, physicians, and third parties should be clarified so that a better understanding of the roles of all parties may be acknowledged and understood.

The second aspect is that any campaign involving the term "Freedom of choice of physicians and hospitals" should have this term uniformly defined so that its meaning is clearly understood whenever it is used. The Principles of Medical Ethics, as revised in June, 1957 contain no specific reference to the term "free choice of physician", but rather deal with conditions under which physicians should dispose of their services and their responsibilities, and conduct themselves in the rendition of medical care. However, in the past two years, the House either has adopted or reaffirmed policy statements on free choice which are reviewed below. While there are no great differences in the concept of free choice as expressed, there are differences in wording which may lead to differences in interpretation.

A. The 1927 statement of the Judicial Council, as reaffirmed by the House in December, 1957 in adopting the report of the Reference Committee on Amendments to the Constitution and Bylaws states, among other tests, that a contract may be determined to be unfair or unethical:

> "When a reasonable* degree of free choice of physicians is denied those cared for in a community where other competent physicians are readily available."

B. The UMWA Suggested Guides, adopted in June, 1957, state that:

> "The fundamental concepts on which the recommendations are based are:
>
> "1. All persons, including beneficiaries of a third party medical program such as the UMWA Fund should have available to them good medical care and should be free to select their own physicians from among those willing and able to render such service
>
> "2. Free choice of physician and hospital by the patient should be preserved.
>
> "a. Every physician duly licensed by the state to practice medicine and surgery should be assumed at the outset to be competent in the field in which he claims to be, unless considered otherwise by his peers."

C. The Guides for Evaluation of Management and Union Health Centers. Adopted December, 1955 and revised December, 1957, while recognizing the existence of closed panels, states that:

> "As one aspect of this responsibility the health center is urged to provide a free choice of medical service to the patient it serves. When service outside a specific center facility cannot be paid for under the terms of the plan, patients should be informed that they are privileged to obtain such services as they wish outside the center at their own expense."

D. The statement on Medical Relations in Workmen's Compensation, adopted in December, 1955 states that:

> "Disabled employees should have the right to accept physicians' services provided by employers, or to select another attending physician from a register of all other physicians in the community willing and qualified to perform the essential service."

In view of the fact that the term "free choice of physician" as used in these various statements and as used alone, out of any context, has resulted in misunderstanding and misinterpretation, it might be desirable to avoid use of this term in the abstract and to speak instead of the conditions under which physicians should dispose of their services and their responsibilities and conduct in the rendition of medical care. Thus, for example, the five points mentioned in the 1927 opinion of the Judicial Council which were reaffirmed and adopted by the House of Delegates in December, 1957 might, if supplemented by additional references to lay domination and quality of medical care, be used as criteria both to evaluate the physician's role in any given program and to determine the likelihood of that program providing the highest quality of medical care to the patient. These points are included in the following excerpt from the 1927 Report of the Judicial Council previously referred to, which states that:

> "Each case must be judged on its own merits after all the facts pertaining thereto are known. There are certain points, however, that may be formulated which, when present, one or more of them, definitely determine a contract to be unfair and unethical. These may be stated as follows:
>
> 1. When the compensation received is inadequate based on the usual fees paid for the same kind of service and class of people in the same community.
> 2. When the compensation is so low as to make it impossible for competent service to be rendered.
> 3. When there is underbidding by physicians in order to secure the contract.
> 4. When a reasonable degree of free choice of physicians is denied those cared for in a community where other competent physicians are readily available.
> 5. When there is solicitation of patients directly or indirectly."

The third aspect has to do with the relationship between the A. M. A. and the state medical associations in the "broad educational campaign" recommended. Since each state has problems peculiar to its area and would need to gear its campaign to these problems, this committee believes that such a project should be carried on through the state medical association offices. The A. M. A. could provide information, printed material, and even slides and proposed talks or news releases for state associations to use as they deemed best.

The Committee believes that the reference to "free choice of . . . hospital" should be reconsidered by the House of Delegates in view of the fact that the hospital is in reality a facility, and choice of facility is not germane to the issue involved.

At the 1958 annual session, the Board of Trustees summarized the Committee's statement in its "Supplementary Report C," together with the Board's recommendation that House action be deferred until the report of the Commission on Medical Care Plans became available. Although the Reference Committee concurred in the Board's recommendation, the House of Delegates amended the report of the Reference Committee by directing the Board of Trustees to proceed immediately with the educational campaign and relieve the Council on Medical Service of further responsibility in this matter.

GUIDES FOR EVALUATION OF MANAGEMENT AND UNION HEALTH CENTERS

In the previous Annual Report, the Committee noted that two changes would be recommended to the House in the text of this Guide. These changes were approved by the House at the 1957 Clinical Session. Following the adoption of these changes, the Committee further recommended to the Councils on Medical Service and Industrial Health that the wording of two footnote references would have to be changed in order to bring this Guide up-to-date. This recommendation was approved by the Councils at their meetings in June, 1958. Future printings of the Guides for Evaluation of Management and Union Health Centers will replace the reference to the 1954 Principles of Medical Ethics with the statement "From the 1954 edition of the Principles of Medical Ethics which are contained in the Opinions and Reports of the Judicial Council (1957) and which have been incorporated in the June, 1957 Principles of Medical Ethics." The reference to "Guiding Principles of Occupational Medicine" will be deleted and substituted with statement on "Scope, Objectives and Functions of Occupational Health Programs," J. A. M. A., Vol. 164, pp. 1104-1106 (July 6) 1957.

1958 SURVEY OF UNION HEALTH CENTERS

In February, 1958 the Committee initiated its third Survey of Union Health Centers. The first two reports on these centers which were published in 1953 and 1954 contained descriptions of twelve and seventeen health centers respectively. The new publication to be issued this fall will contain descriptions of 29 of the approximately 50 such centers in existence. The description of each health center will contain information and data for each plan for the following items: 1) History, 2) membership, 3) objectives of programs, 4) facilities, 5) financing, 6) budget and operating costs, 7) administration, 8) business and professional personnel, 9) benefits, 10) preventive aspects of these services. The 1958 Survey, which will contain information on these plans as of December 31, 1957, was secured as a result of field visits and a questionnaire. The types of medical services provided by union health centers are shown to range from "diagnostic only" to "comprehensive medical care," with the majority of the plans providing diagnostic and ambulatory medical care through closed panels of physicians employed at an hourly rate on a part-time basis, primarily. This survey is one of a continuing series to be conducted periodically in order to keep the medical profession informed of developments in this field.

In view of the numerous requests for copies of this publication, the 1958 Survey will include a copy of the revised Guides for Evaluation of Management and Union Health Centers.

A PRELIMINARY GUIDE FOR MEASURING WORK ABSENCE DUE TO ILLNESS AND INJURY

The last report of the Committee cited the studies, conferences and various published materials on the subject of work absence which had created a considerable amount of interest among many physicians. It was also reported that the Committee was engaged in the preparation of a Guide on the basis of whose definitions and formulas a uniform group of statistics could be compiled by physicians in industry. The preliminary Guide as approved by the Councils on Medical Service and Industrial Health will be published in pamphlet form and distributed this fall to several thousand physicians and other personnel working in this field. The Committee is inviting comments on the Guides it has prepared and plans to issue subsequent revisions based upon the suggestions and experiences of persons who use these Guides in their work.

MISCELLANEOUS

Being prepared for publication and distribution to the medical profession is a summary report on health and welfare plans under collective bargaining. This publication represents a distillation of some pertinent data relating to the provisions of hospital, surgical, and medical benefits in 300 plans which cover approximately five million workers, or over 40% of the total number of employees estimated to be covered by health insurance plans under collective bargaining as of the end of 1955. The material in the Committee's publication is based upon a study prepared by the Bureau of Labor Statistics of the United States Department of Labor. Its publication is considered to be an aid to those physicians and medical societies interested in various types of coverage and provisions of collective bargaining agreements.

The Committee has been authorized by the two Councils to conduct a survey of small plant occupational health programs for the purpose of providing the profession with descriptions of various examples in which such programs operate, the types of service they provide, the relationships of physicians involved in such programs to physicians in the community, and other aspects of the operations of these programs which will be of interest to the medical profession. An important by-product of this study is expected to be the recognition by physicians of the value of such programs, particularly among establishments hiring fewer than 100 employees.

The Committee has devoted some time to discussing the activities of the mobile units and the range of services they provide. At its future meetings the Committee will study this matter in greater detail particularly in determining to what extent is the screening of employees for the express purpose of detecting non-occupational diseases properly a part of an occupational health program.

Committee on Medical and Related Facilities

Since the last report concerning the activities of this Committee, Drs. W. F. Costello, Dover, New Jersey; Edward C. Rosenow, Jr., Pasadena, California; and Wendell C. Stover, Boonville, Indiana; were appointed to replace Drs. E. Dwight Barnett, San Francisco, California; Raymond M. McKeown, Coos Bay, Oregon; and Cleon A. Nafe, Indianapolis, Indiana. Other members are Drs. Willard Wright, Chairman, Williston, North Dakota; Robert L. Novy, Detroit, Michigan; Walter E. Vest, Huntington, West Virginia; David Henry Poer, Atlanta, Georgia; and J. D. McCarthy, Omaha, Nebraska, ex-officio. Staff includes: Mr. George W. Cooley, Secretary, Mr. Joe D. Miller, Research Associate, Miss Dorris Webb, Research Assistant and Miss Barbara Farley and Mr. Nicholas Griffin, Staff Assistants.

The Committee has met on three occasions—September 21-22, 1957 and February 8-9, 1958 in Chicago; and April 19-20, 1958 in White Sulphur Springs, West Virginia.

HILL-BURTON STUDY

The primary task of this Committee during the past year has been the completion of the study of the Hill-Burton Hospital Construction Program. A Progress Report on this study, made to the House in December, 1957, reviewed the study method and called special attention to some aspects of the program that could be improved. The study was completed this spring, and the resume of the findings, the conclusions, and the recommendations were reported to the Council and to the House of Delegates at the June Session. The conclusions and recommendations were approved by both the Council and the House of Delegates.

The recommendations emanating from this two-year study were presented to the United States House of Representatives' Subcommittee on Health and Science (Committee on Interstate and Foreign Commerce) by Dr. Willard Wright, Chairman of this Committee, and Dr. Julian Price, member of the A. M. A. Board of Trustees. This testimony was presented on May 6, 1958 in Washington, D. C.

The recommendations appear in the report of the Council for June, 1958 and it would serve no purpose to review them at this time. However, the Committee would urge that the members of the House discuss both the conclusions and recommendations with their state associations. Copies of the report are available for distribution at this time.

RELATIONSHIP BETWEEN PHYSICIANS IN PRIVATE PRACTICE AND THOSE NOT IN PRIVATE PRACTICE

The Board of Trustees has requested the Council to study the relationships of Doctors of Medicine who are not in private practice to those who are in private practice and to study the problem of actually providing leadership in the extension and strengthening of local health services throughout the nation. The Board stated that "the scope and extent of the problem be determined and that such action as may be needed and desired be taken to strengthen the American Medical Association as an organization for all Doctors of Medicine." The Council in turn, directed this Committee to undertake this study. This study is now under way and will be reported when completed.

PHYSICIANS PLACEMENT SERVICE

The results of the activities of the physicians placement services of the state medical associations and of the American Medical Association for the year July, 1957 through June 30, 1958 reflect the increased efforts of these services, both individually and collectively. Since the recommendation of the House of Delegates in June, 1951, for an expansion of the Council's Physicians Placement Service as well as that of the states, there has been an increase in both the type and amount of service.

For the past two years the Committee has reported that some type of placement assistance is available through each state medical association. More states indicate that more information is being secured for the community files when additional medical care is being sought; however, there are still some listings from the states that contain only the name of the town and a contact person. For many a young physician seeking a location for practice, the printed list of opportunities secured from the state medical association is the determining factor as to whether he and his family will visit that state and look at potential sites for their home. The young physician who looks at a list composed only of the names of towns and the contact person, may well ask what the list means. A thorough and distinctive description of each community seeking more medical care does take time, but if a sincere effort is being made to provide people of the state with more medical care, that time would seem to be well spent.

Some of the states offering descriptions of location opportunities, such as Illinois, Texas, Wisconsin, and California were leaders last year in the percentage of positions filled; perhaps other states should be mentioned but not all states indicate whether a position has been filled or has just been dropped, when it no longer appears on a list. Ohio, Illinois, Iowa, Virginia and Alabama have developed effective systems for notifying both physicians seeking a location and the A. M. A. of positions that have been filled or dropped. It is to be wondered if limited information could be the reason 28% of the physicians requesting location information decided to practice in a state not listed on their questionnaire.

A definition has not been offered for the requirements of a formal placement service. However, a number of self-termed informal services appear to have developed an excellent system of records and get a high percentage of placements; perhaps their services are more formal than they realize. All but six state placement services supply the American Medical Association with a list of opportunities for practice. Lists for two of these states are secured through other medical organizations in the state. An increasing number of states are preparing frequent revisions of their location for practice lists. The fact that most of these are regularly supplied to the Committee, without a request having to be made, has been helpful. The cooperation of the staff members of the state medical associations working with placement service activities has been appreciated by the staff working with this Committee.

Physician Requests.—During the year the number of physicians who have completed questionnaires for the Placement Service totaled 1,030. As of July, 1957, there were 866 physicians listed in the open file. This brings close to 2,000 the number of physicians, listed during the current year. Almost 1,500 physicians were listed the preceding year.

Most of these requests came from physicians who had recently completed an internship or residency and were seeking an initial location. The remainder consisted of physicians completing their period of Military Service, and physicians seeking to relocate. The majority of the requests were received by letter, reaching a monthly maximum of 205 in January. However, almost 300 physicians visited the office personally. Many of these were making cross-country trips to get a picture of the location opportunities available and were generally accompanied by their wives.

At six-month intervals physicians are contacted to see whether a location has been decided upon. Response to this follow-up is good, usually ranging over 80%. During the past year 35% of the physicians seeking a location were general practitioners, 14% were internists, 13% were surgeons, 7% were obstetricians and gynecologists, 5% were pediatricians, and the remaining 26% were divided among other specialties. The three states attracting the largest number of the physicians listed in the Placement Service files were California, Illinois and New York. General practitioners seemed more interested in information about opportunities in Illinois, California, Pennsylvania, New Jersey and Ohio. The specialists were most interested in California, New York, Illinois, Oregon and Arizona.

Community Requests.—During the year, 2,353 areas were listed as seeking a general practitioner. About one out of every six of these requests were for association with one or more physicians already in private practice. The increase in the current listings of 1,694 areas over the 1,355 listed at the time of the 1953 annual report may well be some reflection of the increase in the activity of both the state and the A. M. A. placement services. A breakdown of these requests for general practitioners by size of community is given below for the years 1953 and 1958.

General Practice Openings
by Size of Community

	Community Population up to 1,000	Community Population 1,001-2,000	Community Population 2,001-5,000	Community Population over 5,000	Total
1958	903	316	233	242	1,694
1953	764	264	165	162	1,355

Five states, Minnesota, North Carolina, Illinois, Wisconsin, and Michigan account for 583 of the 1,694 listings. Although this is hardly what one would expect, it is accounted for by the fact that 1) all these states have active placement services, and 2) many state placement services list all requests while others list only those that they feel can support a physician.

A review of the 521 specialty listings now in the placement service files shows the largest number of requests, in descending order, are for specialists in internal medicine, pediatrics, EENT, psychiatry, and ophthalmology. Most of these are requests for specialists to associate with another physician or to join a group. Among the states appearing most often in the specialty listings are Illinois, North Carolina, Wisconsin, Iowa, and Minnesota. Of the approximately 400 specialty openings filled during the year, the greatest number were in pediatrics, internal medicine, and surgery.

All requests to the A. M. A. from physicians seeking a location for practice and from communities, and others, seeking a physician are referred to the appropriate state.

State Placement Activities.—Five years ago, the two regional placement service conferences which were held included a number of states with either no placement service or an inactive one. These conferences were held at locations drawing a greater part of their representation from the southern states. During the past year all of the state medical associations, except three, participating in the two placement service conferences have been visited by a member of the Council's Placement Service staff. Reports on these visits have been prepared for publication in THE JOURNAL.

Every one of these states now has an active, working and cooperating placement service. All make use of formal questionnaires and card files and in all except one state, a listing of opportunities for practice is available. All except one state has a medical scholarship program (Kentucky has two) designed to aid medical students who plan to practice where the optimum distribution of medical care is still to be attained. In Alabama, Kentucky, and Mississippi the medical student who practices for five years in an area approved by the respective scholarship boards does not have to repay the loan. However, only Kentucky will accept out-of-state applicants for this program.

Alabama and Texas are the only states reporting a formal physician distribution survey which has applied the Community Rating Schedule. This Schedule, developed in 1953 by the Committee on Medical and Related Facilities, offers the state placement service a means of rating communities seeking more medical care, as to

(1) need priority, from the standpoint of the community, and

(2) desirability priority, from the standpoint of the physician.

A summary of the Texas survey appeared in the January 22, 1955 issue of THE JOURNAL and a summary of the Alabama survey will be published this Fall. The information obtained in each survey was, and still is, valuable in itself; however, the Committee in each state makes special mention of the excellent public relations value achieved by the visits to the communities, as well as by the correspondence.

The Medical Society of the State of North Carolina, as a result of a study, has prepared a card file which provides interested physicians with a county summary showing locations of practicing physicians and also includes the type of practice and the age range of each. This can be particularly helpful to the physician wishing to establish a solo practice. A detailed report of the activities of this placement service appeared in the May 10, 1958 issue of THE JOURNAL. Tennessee has an additional placement aid in the Tennessee Medical Foundation, organized for the purpose of bringing better distribution of health care to the people of Tennessee. The Tennessee State Medical Association is unique in using a numerical code instead of names when listing both communities and physicians. The medical scholarship program of the Nashville Academy of Medicine is so new that the first participating medical students are still in school.

Pennsylvania and Michigan had a formal placement service in an early developmental stage, five years ago, at the time of the placement conferences. The Pennsylvania placement service has developed an excellent system of forms to gather information for and from inquiring physicians. So interested are the physicians in the state in insuring the best distribution of medical care in Pennsylvania, that the Public Relations Conference of the 1958 annual meeting of The Medical Society of the State of Pennsylvania is to devote time to this subject. The Michigan Health Council, under the auspices of the Michigan State Medical Society, has the only full time physicians placement service director in any state. The efforts of the Michigan staff are devoted to serving the communities and physicians within the state and provides them an opportunity to become familiar with this active, result-getting service.

The Oklahoma State Medical Association was also in the area covered by the Conference and was in the group of states visited during the past year. Recently developed questionnaires collecting pertinent physician and community information are now being used to advantage, and a printed listing is available to those physicians seeking a location for practice in the state. Oklahoma was among the first of the states to give State Journal space to a list of physicians seeking location opportunities. For physicians in the state seeking an associate, as well as for groups interested in additional personnel, this is an excellent source of information.

A little over ten years ago the now well-known Kansas Plan for bringing more medical care to the people of the state was initiated. Through the combined effort of the medical profession and of the laymen of the state this three-way program is providing more and better distributed medical care for Kansas. The initial phase of the program was an enlargement of the Kansas School of Medicine. The second phase, which is a continuing one, was a cooperative one between the Kansas Medical Society and the Kansas School of Medicine to encourage the communities that needed and could support a physician to provide adequate facilities in which one could practice to the advantage of the community. A number of these towns have achieved national recognition through newspapers, magazines, and television. A list of towns requesting assistance in securing more medical care is supplied to the Council office by the Kansas School of Medicine. The third phase of the program has been of service not only to the practicing physicians of Kansas, but also to neighboring states. This part of the program provides short postgraduate courses around the year to physicians who can come to the medical school and even, in some cases, to those who do not manage to get that far from home. The cooperation between the Kansas Medical Society and the Kansas School of Medicine is paying medical dividends to the people of the state.

Publicizing the Physicians Placement Service.—Two specific means have been used to call the placement services to the attention of medical students, interns and residents: (1) a simple check sheet in the form of a leaflet, *LOOK BEFORE YOU LEAP. . . .* into the selection of a place to practice," was prepared for the use of the physician seeking a location for practice. The list raises pertinent questions related to

(a) the community need,
(b) the desirability of the location from the viewpoint of the physician's family, and
(c) the desirability of the location, from the physician's viewpoint.

Potential sources of placement information are included in the leaflet. Approximately 30,000 of these check sheets have been distributed since it was printed in April of this year. The bulk of this number has gone to the state placement services and to the executive secretaries of the county medical societies for further distribution. These have been made available to physicians seeking a location, and have been used in connection with the Senior Day programs which state associations co-sponsor with the medical schools. The secretaries of the county medical societies were also requested to supply the teaching hospitals with sufficient copies of the leaflet to reach each intern and resident.

(2) The Physicians Placement Service exhibit designed for the physician seeking a practice location, was shown at the Student A. M. A. meeting held in Chicago, May 2-4. An exhibit for this group on placement information has little immediate value because of the small number of interns and residents attending. However, each year more physician questionnaires secured at the Student A. M. A. meeting are returned by the students still in medical school. Some letters to the placement service attest to the fact that interns and residents remember having first heard of the service through a Student A. M. A. meeting.

GROUP PRACTICE

For the past several years the Committee has been collecting information to be used in preparing a directory of group practice units. The current card file contains 1,008 such groups, located in the United States, Hawaii, and Canada. Sources of information for this file have been the membership rosters of the American Association of Medical Clinics and the National Association of Clinic Managers, newspaper clippings and stationery letterheads.

Recently an information sheet was sent, for verification, to each of the groups in the file. A breakdown of the 822 sheets returned shows

689	groups with more than two physicians
100	groups with only two physicians
8,958	physicians practicing in these groups
18	indicate their group has been dissolved
15	former two-man groups are now individual practices

Representatives of the American Association of Clinic Managers, the National Association of Clinic Managers, and this Committee held a conference in Kansas City during the 1957 meeting of the American Association of Medical Clinics. Among the items covered was the following suggested definition of "group practice":[1] "Group medical practice is the application of medical services to the needs of the patient by a number of physicians working in systematic association with the joint use of office facilities, equipment, and technical personnel; and with centralized administration and financial organization."

SEARS-ROEBUCK FOUNDATION

The Committee has continued to cooperate with the Sears-Roebuck Foundation program to assist communities in planning medical facilities. This program presently is directing communities in making a survey to determine whether or not a physician could be supported by the area and is needed. If the survey is positive, guidance is available in raising money for a medical facility. Floor plans are provided by the Foundation, for either a one or two physician facility. The building in Rochelle, Georgia will be the first of the facilities to be completed. Both the state medical associations and the A. M. A. are kept informed of all community requests and assistance given by the Foundation.

---

[1] Neither the Council nor the Committee on Medical and Related Facilities has as yet approved any definition of group practice and will not do so until such a definition can be related to a definition of other terms, such as clinic, medical clinic, and medical center.

The leaflet, "DOCTOR . . . . here is an opportunity for you," and the booklet, "Plan for Community Medical Assistance," have been made available to the state associations for distribution and single copies are sent to inquiring physicians and communities.

A. M. A.–A. N. H. A. LIAISON COMMITTEE

In the early part of 1957, with the approval of the Board of Trustees, the Council on Medical Service re-established a Liaison Committee between the American Medical Association and the American Nursing Home Association. A. M. A. representatives to this committee are Drs. Willard A. Wright, Williston, North Dakota, Chairman of the Council's Committee on Medical and Related Facilities, Dean W. Roberts, Chicago, Illinois, a member of the Committee on Indigent Care, and Frederick C. Swartz, East Lansing, Michigan, a member of the Committee on Aging. The Liaison Committee has held three meetings during the year: in September, 1957, and in February and May, 1958.

One of the important activities growing out of these meetings has been the decision to develop suggested guides and standards for medical care in nursing homes. To this end, staff members of the Council are visiting a select group of the better skilled nursing homes in 22 states this summer, in an effort to determine the type of medical care and supervision actually being provided in these facilities. This information will provide a basis for developing workable guides and standards for all skilled nursing homes. In addition to this information, the staff will also obtain data on other important areas of nursing home operation, such as rehabilitation, social service, plant and equipment, and costs. Concurrently with this field survey, questionnaires covering much the same area of operation are being mailed from the American Nursing Home Association's national office to approximately 4,500 member homes throughout the country. Tentative plans call for the results of these two surveys to be published sometime this fall, along with "Recommended Guides and Standards for Medical Care in Nursing Homes."

Other problems currently under study by the Liaison Committee are the adequacy of welfare payments for nursing home care, ways of financing new and improved nursing home facilities, and stimulating a better working relationship between nursing homes and physicians at both the state and local levels.

Committee on Prepayment Medical and Hospital Service

The membership of the Committee on Prepayment Medical and Hospital Service is composed of Drs. Percy E. Hopkins, Chicago, Chairman; John Conway, Clovis, N. Mex.; Charles G. Hayden, Boston; Quentin Kintner, Port Angeles, Wash.; Robert L. Novy, Detroit; O. B. Owens, Alexandria, La.; Carl F. Vohs, St. Louis; Carlton E. Wertz, Buffalo; and J. D. McCarthy, Omaha, ex officio. Mr. Howard O. Brower serves as Committee secretary assisted by Mr. John Guy Miller, Research Associate and Mrs. Ann McConnell, Staff Assistant. Since the last annual report the Committee has had four meetings. Two meetings were held in Chicago, one in Washington State, and one in Texas. At both the Washington and Texas meetings physicians and plan executives from those and contiguous states discussed many problems relating to insurance and prepayment plans.

VOLUNTARY HEALTH INSURANCE

Blue Shield and Other Medical Society Approved, and Blue Cross or Blue Cross Coordinated Plans: The number of persons enrolled in voluntary health insurance plans which are either approved or sponsored by medical associations or coordinated with local hospital benefit plans increased during 1957 to a total of 44,890,863. This represents an increase of 2,610,405 over the figure of 42,280,458 at the end of 1956.

All Types of Insurance Mechanisms: All insurance and similar mechanisms designed to assist in financing health care continued to report impressive enrollment gains. By the end of 1957 approximately 121 million persons had some kind of hospital expense protection. That represented a 4.7% increase for the calendar year. The extent of surgical expense protection of all types increased 2.5% covering 109 million persons. The number of persons having regular medical expense insurance increased 10.7% covering approximately 72 million people. Those having major hospital and medical expense coverage at 1957 year end totaled 13,262,000, an increase of 49.4%.

TABLE 1.—*Distribution of Hospital, Surgical, and Regular Medical Expense Coverage By Type of Insuring Organization, Dec. 31, 1957*

	People Protected, No.		
Type of Insuring Organization	Hospital Expense	Surgical Expense	Regular Medical Expense
Insurance Companies:			
Group Insurance	48,439,000	48,955,000	28,317,000
Individual—Policy Insurance	28,673,000	24,928,000	7,371,000
[illegible]	77,112,000	73,883,000	35,688,000
[illegible] * in Company Protection	6,920,000	6,427,000	2,448,000
Net Total for Insurance Companies	70,192,000	67,436,000	33,240,000
Medical Society Plans (Blue Shield) and Blue Cross†	54,923,000	45,383,000	36,926,000
Independent Plans:			
Industrial Plans	3,126,000	3,220,000	3,081,000
Community Plans	665,000	1,172,000	1,177,000
Consumer Sponsored Plans	165,000	303,000	233,000
Private Group Clinics	591,000	602,000	628,000
College Health Plans	400,000	300,000	900,000
Total for Independent Plans	4,947,000	5,397,000	6,019,000
Deduction for Duplication:			
Persons Protected by More Than One Type of Insuring Organization‡	8,630,000	9,305,000	4,372,000
Net Total, Persons Protected	121,432,000	108,931,000	71,813,000

---

* Number indicates those who may carry insurance with more than one company.

† Includes some plans which may not be medical-society-approved; hence the variance between the HIC figure and the A. M. A. figure as shown previously.

‡ Estimated number of persons who carry both insurance company and Blue Shield-Blue Cross or similar contracts.

Voluntary Health Insurance Benefits Paid

	Type of Insuring Organization			
Type of Benefit	Blue Shield Blue-Cross	Insurance Companies	Independent	Total
Hospital Expense	$1,159,000,000	$1,080,000,000	$101,000,000	$2,340,000,000
Surgical and Medical Expense	478,000,000	575,000,000	114,000,000	1,167,000,000
Total	$1,637,000,000	$1,655,000,000	$215,000,000	$3,507,000,000

The figures in the preceding paragraph as well as those shown in the following tables were obtained from the 12th Annual Survey of the Health Insurance Council on "Voluntary Health Insurance in the United States."

As in the past, the Committee on Prepayment Medical and Hospital Service assisted the Survey Committee of the Health Insurance Council along with the Blue Shield and Blue Cross Commissions, insurance companies (through their trade associations) and other contributing organizations. All figures were compiled and collated to eliminate duplication in reporting the numbers insured as explained in the footnotes to the foregoing table.

In releasing the 1957 year-end figures, the Health Insurance Council estimated that, by the middle of 1958, hospital expense benefit enrollment had increased to some 123 million persons, with surgical and regular medical expense benefit coverages extending to 111 million and 74 million respectively. Moreover, the major hospital and medical expense benefit figure was then estimated to be 15 million. These interim estimates would indicate that over 70% of the entire United States civilian population is currently protected by some form of voluntary health insurance.

Growth in number of persons insured does not tell the full story. Medical-society-approved plans and other programs are continuing to (1) reevaluate underwriting practices regarding age limits, size of groups and individual enrollment; (2) make improvements in existing coverage; and (3) experiment in newer types of benefits and coverage.

The amount of health care financed through the medium of insurance and similar mechanisms has attained significant proportions as reflected by the sums reported in claims during 1957. This is evidenced by the following table which indicates the disbursements by category of expense and by type of insuring organization.

COMMITTEE PUBLICATIONS

The health insurance brochure entitled "Voluntary Prepayment Medical Benefit Plans" was revised this year, as well as the supplementary pamphlet "Charts and Graphs". Copies of each were mailed to the members of the House of Delegates, Board of Trustees, and officers of the Association, state and county medical society secretaries and executive secretaries, plans listed in the brochure, and hospitals with approved internships and residencies in addition to a large number sent in response to individual requests.

The popular pamphlet "Growth in Voluntary Health Insurance" is in the process of revision. This publication summarizes the total enrollment information relating to all types of programs and also defines the meanings of certain terms used in the health insurance field.

HEALTH INSURANCE CLAIM FORMS

The Council office continues to hear of interest in simplified claim forms which were developed by a special committee of the Health Insurance Council at the request of the A. M. A. These forms are used in securing medical data and opinions essential to insurance claim processing. The Health Insurance Council, through its participating associations, continues to encourage companies in their use. It has distributed brochures to the industry which outline the purposes for which the forms were designed as well as the background of their development.

The Council office continues to receive periodically expressions of dissatisfactions from physicians when they are called upon to complete multiple copies of claim forms for a claim involving the same illness and the same person. It is of course understandable, in those instances where insured patients are protected by more than one type of coverage for the same contingencies, that it is necessary to provide each insuring organization with appropriate information.

We have continued our efforts through contacts with medical directors of insuring organizations so that physicians will not be called upon to undertake any non-essential clerical duties in connection with claim processing. In all instances, these medical directors have been both sympathetic to the problems and cooperative in taking appropriate steps to remedy them. In view of this the Council office believes it is in a unique position to assist physicians who receive requests to complete multiple copies of forms for the same claim.

Members of the profession are therefore encouraged to communicate with the Council office at any time they feel assistance is either necessary or desirable.

INSURANCE ABUSES

Although it is impossible to maintain an accurate record of insurance committees either within constituent associations or component societies, it would appear that the mechanisms now available are effecive. This assumption is based upon the fact that a decreasing incidence of alleged insurance abuses is reported to the Council office. As in the past, whenever the Council on Medical Service does receive complaints involving either misunderstandings or suspected insurance abuses, these are referred to appropriate committees at the local level so that the questions may be resolved equitably and expeditiously.

PRE-RETIREMENT FINANCING OR "PAID-UP" HEALTH INSURANCE

At the 1957 Clinical Session a portion of the Council report dealt with the problem of Pre-Retirement Financing of Health Insurance. At that time, a specific proposal had been submitted for consideration. However in the opinion of the Council and the Committee on Prepayment Medical and Hospital Service, the suggested proposal contained certain elements which were deemed incompatible. That report mentioned the variety of approaches to the problem, including those now in use and also those which are under consideration. The Reference Committee encouraged a continuation of these studies.

Insuring organizations, including Blue Shield, as well as Legislative Commissions and others, are showing increasing interest. Resolution #7, relating to this subject as modified and adopted by the House of Delegates during the 1958 Annual Session, has been referred to the Council on Medical Service for further study.

SUGGESTED GUIDES FOR MEDICAL SOCIETY SPONSORED VOLUNTARY PREPAYMENT MEDICAL BENEFIT PLANS

At the 1958 Annual Session, the Council submitted to the House of Delegates suggested guides for medical society approved health insurance programs. Upon recommendation of the Reference Committee these suggested guides were re-referred to the Council for further study and report at the 1958 Clinical Session.

The Council is proceeding with a further review and analysis of the suggested guides, and will submit a supplementary report at the time of the Clinical Session.

OTHER ACTIVITIES AND LIAISON

In the period covered by this report, members of the committee as well as members of the Council and other Headquarters staff attended a wide variety of meetings dealing with insurance and related activities. These included both the Annual Meeting and the Professional Relations Conference of Blue Shield, the Annual Meeting of the Health Insurance Association of America, and the Annual Meeting of the Association of Life Insurance Medical Directors of America. Throughout the year there have been frequent contacts with officers of the Medical Section of the American Life Convention as well as discussions with those engaged in administering professional liability insurance. In addition, consideration has been given to suggested new methods of financing health care as well as suggestions for modifying the method of rating professional liability insurance.

The foregoing are examples of activities in addition to the frequent and continuing contacts with the Blue Shield Commission Staff and the Staff of the Health Insurance Council. As some of these newer developments progress they will be reported promptly to the profession.

Committee on Relations with Lay-Sponsored Voluntary Health Plans

The membership of the Committee on Relations with Lay Sponsored Voluntary Health Plans is composed of Drs. H. Russell Brown, Watertown, S. D., Chairman; Lewis A. Alesen, Los Angeles; F. J. Elias, Duluth, Minn.; J. Stanley Kenney, New York City; George S. Klump, Williamsport, Pa.; Hoyt B. Woolley, Idaho Falls, Idaho; Mr. C. H. Crownhart, Madison, Wisconsin; and Dr. J. D. McCarthy, Omaha, ex officio. Staff member is Mr. Howard O. Brower, Secretary.

The Committee has held no scheduled meeting during the period of this report. Primarily this is because the Commission on Medical Care Plans is concerned with many aspects of lay-sponsored voluntary health plans which normally are within the realm of this Committee's interest. Two members of this Committee also serve on the Commission on Medical Care Plans.

Although no formal meetings have been held, the Committee continues to receive information with respect to health benefit programs within the field of its official interest.

It is the understanding of this Committee that the Commission anticipates the filing of its final report by the time of the 1958 Clinical Session.

Respectfully submitted,

Joseph D. McCarthy, M.D., Chairman
John Flack Burton, M.D.
Reuben B. Chrisman Jr., M.D.
Thomas J. Danaher, M.D.
J. Lafe Ludwig, M.D.
Robert L. Novy, M.D.
Russell B. Roth, M.D.
Carlton E. Wertz, M.D.
Hoyt Woolley, M.D.
David B. Allman, M.D.
George W. Cooley, Secretary

COUNCIL ON CONSTITUTION AND BYLAWS

During the period covered by this report (July 1, 1957, through June 30, 1958) the Council on Constitution and Bylaws met three times for the purpose of considering problems which had been referred to it. Those matters which demanded the most time and which were subsequently considered by the House of Delegates at the June meeting related to the Heller Management Survey, Service Membership for Veterans Administration physicians, and the Scientific Assembly.

Heller Management Survey.—It will be recalled that prior to the Clinical Session in Philadelphia, a management survey of the American Medical Association headquarters office was made and referred to a special committee of the House of Delegates for study. This Committee, known as the Hyland Committee, reported to the House in December, 1957. At that time, the House approved a number of changes in the Association's Constitution and Bylaws, including a restatement of the composition of the Board of Trustees, a combining of the offices of Secretary and Treasurer, the elimination of the positions of General Manager and Assistant Secretary and the substitution therefor of an Executive Vice President and an Assistant Executive Vice President. With the approval of these changes, the whole matter was referred to this Council for the purpose of preparing the wording necessary to effectuate them. The required amendments to more than forty sections of the Constitution and Bylaws were submitted to the House in San Francisco in June, 1958, and approved without a dissenting vote.

Service Membership for Veterans Administration Physicians.—Resolutions presented to the House of Delegates at the Philadelphia meeting questioned the wisdom of permitting physicians employed by the Veterans Administration to become Service Members of the Association and thus exempt from the payment of dues and the restraints and disciplines resulting from active membership in a component society. On the basis of the oral and written suggestions which the Council received on all facets of the problem, it recommended that such physicians should no longer be eligible for Service Membership. This recommendation did not meet with the approval of the House in San Francisco and the matter was referred to the Council. The Council was directed to try to find some method of encouraging all Service Members, not just Veterans Administration physicians, to join a component medical society if eligible to do so. This matter will be reported to the House at a future time.

Scientific Assembly.—A committee to study the Scientific Assembly, appointed by the Speaker of the House of Delegates following the Philadelphia meeting, met with the Council to discuss some Bylaw changes which the committee felt would result in a more efficient functioning of the Scientific Assembly. These changes were subsequently submitted to, and approved by, the House in San Francisco.

Future Problems.—Problems which will be discussed at future meetings of the Council include the Service Membership issue, the question of exempting resident physicians from the payment of dues during the course of their residency study, and the question of whether or not to recommend the substitution of Sturgis' Standard Code of Parliamentary Procedure for Robert's Rules of Order.

New Printing of Constitution and Bylaws.—Because of the many changes in the Constitution and Bylaws adopted by the House in San Francisco, a new printing of these documents is necessary. Copies may be obtained by writing the Council's Secretary at AMA Headquarters.

Personnel Changes.—The term of office of Dr. Stanley H. Osborn of Hartford, Connecticut, a charter member of this Council, expired in June, 1958. He was replaced by Dr. William D. Stovall of Madison, Wisconsin. Dr. Floyd S. Winslow of Rochester, New York, also a charter member of the Council, died during the year. Elected to serve the balance of his term was Dr. William Hyland of Grand Rapids, Michigan. Dr. Warren W. Furey of Chicago was elected to the Board of Trustees. Elected to serve the balance of his term was Dr. W. C. Bornemeier, also of Chicago.

Respectfully submitted,

B. E. Pickett, M.D., Chairman
Walter E. Vest, M.D.
William D. Stovall, M.D.
William Hyland, M.D.
Walter C. Bornemeier, M.D.
George E. Hall, Executive Secretary.

WOMAN'S AUXILIARY

The San Francisco Convention of the Woman's Auxiliary to the American Medical Association was a return to the scene of the first annual meeting held in June 1923. This brought to a close the thirty-sixth year of Auxiliary activity and service. During the year, the Auxiliary became incorporated (not for profit). This summary covers the year 1957-58 under the presidency of Mrs. Paul C. Craig. The theme for the year again pinpointed our area of service in health education: Health Is a Joint Endeavor. This theme also stands as a beacon to our existence as an auxiliary. We cooperate with the American Medical Association. They lead. On national, state and county levels, we seek advice and guidance—a joint endeavor.

Reports from forty-eight states, Alaska and Hawaii showed that our activities have been chiefly in the realm of health education. Safety at home, especially for the aged, the very young, and the handicapped was stressed in 1957-58. Many projects were directed toward safety on the highways, driver training and fitness. Health programs and science fairs participation has been predominant in many state reports.

Individually, members are the golden thread which unites us with other individuals and other forces concerned with individual and community health. We have striven to keep our membership informed so that we can increase our effectiveness in leadership and health matters as an auxiliary.

Increased cooperation in legislation has resulted from the attendance of our national chairman, Mrs. Charles L. Goodhand, at meetings of the American Medical Association Committee on Legislation, the appointment of Legislative Key Women, and the generosity of the A. M. A. Committee in sharing its information and findings with the Auxiliary committee. This cooperation has given the Auxiliary the strength, advice and guidance which we need and seek. Our executive secretary, Miss Margaret Wolfe, was appointed a member of the A. M. A. Task Force, and kept the Auxiliary informed of this group's activities.

Mrs. Paul C. Craig commented in her annual report, "The most important things we were trying to accomplish this year: an evaluation of our work, exploration of methods used by groups to improve their productivity, and building closer working relationships with our medical associations.

"... During visits to state conventions this spring I have always referred to A-B-C. A—stands for David B. Allman, M.D., whose words on the President's Page of the George Washington's birthday issue of THE JOURNAL (JAMA, Feb. 22, 1958) gave us the: B—biggest boost of the year in: C—cooperation with our doctors. This has been invaluable; coming from the physician heading the American Medical Association it has intrinsic and intangible value of great significance for the future. Thank you, for all of us, Dr. Allman."

Our cardinal concern has been that you know the value of the cordial cooperation, advice and guidance given us by representatives of A. M. A. Drs. David B. Allman, Gunnar Gundersen, George F. Lull, and members of the Board of Trustees have given freely of their time and guidance to many of our leaders as occasion has arisen. Dr. Ernest B. Howard is our liaison to the Advisory Council. He has given many hours to consult with us and guide us. At each of our national meetings, convention and conference, he gives the "A. M. A. Roundup," an up-to-the-minute summary of events about which it is important that we have accurate information. It is always helpful, and enthusiastically received by our members.

In 1957-58 every department of the A. M. A. has given assistance to the Auxiliary officers—national and state. The alacrity with which requests by mail are answered must be commended. National and state officers receive the Washington Letter and other publications from A. M. A. Staff members and chairmen of many departments and councils have appeared on our conference panels and convention round tables. We have developed Auxiliary activities in consultation with the Committee on Civil Defense of the Council on National Defense, Bureau of Health Education, Law Department, Committee on the Medical Aspects of Automobile Injuries and Deaths, Council on Medical Service, Council on Mental Health, Department of Public Relations, Committee on Rehabilitation, and the Council on Rural Health. We are fortunate to have headquarters in the A. M. A. Building at 535 North Dearborn Street, Chicago, and we express our thanks for the offices provided for us. Miss Margaret N. Wolfe, Executive Secretary, heads a staff of five members who efficiently and tactfully carry on the many details of our work, including the quarterly publication of our official Bulletin.

The two specific projects to which the American Medical Association requested that we direct our efforts have been our major concern: Auxiliary members were proud to report, 57,502 *Today's Health* credits in 1957-58; we contributed $126,366.38 to the American Medical Education Foundation, which is an aggregate sum from all constituent auxiliaries and a percent from our national budget. Our gifts to A. M. E. F. since 1951 total $521,300. These two projects have gained momentum from one year to the next because of the excellent direction from your staff. Our chairmen are always enthusiastic in acceptance of this assignment.

Recruitment has become increasingly important since it has been broadened to include paramedical careers, adding new members to the team. We have provided $144,590 in scholarships and loans this year.

At the 1958 convention we voted token gifts of $100 to the United States Committee of the World Medical Association; $100 to the Crusade for Freedom; $100 to the Student American Medical Association Foundation (a loan fund for medical students); and $5,000 to the American Medical Education Foundation in memory of deceased members during the year 1957-58.

During the past year, Mrs. Paul C. Craig, Mrs. William Mackersie and Mrs. George Garrison, assisted in the organization of the Woman's Auxiliary to the Student American Medical Association. The first constitutional convention of the Student A. M. A. Auxiliary was held in Chicago in May, 1958, after a year of ground work in which the A. M. A. Woman's Auxiliary served in an advisory capacity. Mrs. George Garrison was the first officially appointed liaison between the A. M. A. Woman's Auxiliary and the Student A. M. A. Auxiliary, and was present at the meeting in Philadelphia in May, 1957, when the organization of a Student A. M. A. Auxiliary was discussed. As Mrs. Craig stated in her annual report "assisting this group may well prove to be the most important thing we did during the year 1957-58."

The national president of the Auxiliary attends state conventions or conferences and represents the National Auxiliary at meetings of many groups concerned with health as well as numerous non-medical meetings. Mrs. Craig attended thirty-one state meetings; other officers or chairmen visited twenty, including Alaska, which was visited for the first time. She appeared before the A. M. A. House of Delegates at both the Interim and June sessions and was a guest at the Public Relations Institute; the conferences on Mental Health and Rural Health; the A. M. E. F. Board meeting; Interim Session; Conference of Physicians and Schools; Rural Health Conference; and the planning meeting for Medical Education Week. She also represented the Auxiliary at meetings of the American Cancer Society; National Society for the Prevention of Blindness; President's Conference on Children and Youth; Woman's Advisory Council of Federal Civil Defense Administration; National Foundation for Infantile Paralysis; President's Committee on Employment of the Physically Handicapped; President's Committee on Traffic Safety and Regional meetings; National Safety Congress; Automotive Safety Foundation; and informal meetings of the American Dietetic Association and Hospital Auxiliaries. In our effort to effect a smooth transition from one administration to the next, where possible the president-elect, other officers and our executive secretary also attended many of these meetings. This was planned by Mrs. Craig so that our activities would not lose momentum.

Our total membership is approximately 77,713. National active members are the wives of active or service members of the American Medical Association (or widows of men who were in good standing at the time of their deaths). National associate members are those members of constituent auxiliaries who do not qualify for active membership.

Following the San Francisco convention officers reviewed their plans for the coming year. Realizing the truth of the statement of David B. Allman, M.D., 1957-58 president of the American Medical Association—

"... In recent years we have seen a narrowing of the breach that once existed between science and religion. And in medicine we are witnessing even more than that; not only mutual respect in the area of thought and philosophy, but also an actual, practical merging of efforts.

"In my opinion, this trend offers great hope and encouragement for the cause of brotherhood. Medicine and religion both speak a universal language—applicable to all men and understandable by all men. Religion provides health and healing for men's souls, and teaches them to love their brothers. Medicine provides health and healing for men's bodies and minds, and it exists for the service of all humanity. Both are the essence of brotherhood. Medicine and religion, working actively together under the protective warmth of American democracy, can contribute immeasurably to the cause of brotherhood—here and abroad." And Gunnar Gundersen, M.D., 1958-59 president—"The medical profession is fortunate in that it knows no curtain of any kind, whether it be iron or bamboo, and stands willing to share its information with everyone for the purpose of improving health conditions everywhere."—these messages have opened new horizons and inspired us to extend a helping hand to our neighbors. We give thought to our Auxiliary, its activities, and our personal actions. For the coming year we have pledged to make a united effort to consolidate the value of our citizenship by participating in worthwhile community and social activities which will further the good of all. Mrs. Frank Gastineau, our President-Elect, and I planned the October Conference of National Officers, Chairmen and States Presidents and

Presidents-Elect around the theme "Auxiliaries *in Action*" so that we might increase our effectiveness in community service. Thus, in keeping with our 1958-59 *theme*, we will "Safeguard Today's Health for Tomorrow."

Mrs. E. Arthur Underwood, President

AMERICAN MEDICAL EDUCATION FOUNDATION

This report of the American Medical Education Foundation covering the period from July 1, 1957, to June 30, 1958, summarizes the results of the 1957 year and describes the activities of the first half of the Foundation's eighth year.

It is with pleasure that we report the Foundation's steady financial growth in its aid to the nation's 85 medical schools Through the A. M. E. F., physicians and their medical societies have assisted medical education with gifts totaling more than 7 million dollars.

At the close of the Foundation's seventh fiscal year on Dec. 31, 1957, the total of contributions received since 1951 was $6,741,924. In this last calendar year it is gratifying to report that the number of contributors increased from 39,892 to 44,155 with a total income of $984,786.83. During the spring months of 1958 the Foundation reached and passed the 7-million-dollar mark.

The American Medical Education Foundation takes pride in this significant increase in income, but it also would like to report the development across the country of interest and enthusiasm in the program which has been demonstrated by the development of committees and the efforts of the state and county societies, and by the recognition of the importance of its progress in meetings everywhere. In addition, the Foundation can point to a significant increase in the concern of the physician for his individual school as demonstrated by the greater support for alumni appeals during the past few years.

The Foundation's efforts have awakened the physician to the needs of the medical schools; however, it has also demonstrated to many others the concern of the medical profession over these needs and thus stimulated additional sources of income for the schools.

Distribution of Annual Grants to the Schools

In February, 1958, the American Medical Education Foundation made its second direct distribution of funds to the medical schools. (Until two years ago the A. M. E. F. grants were distributed jointly with the National Fund for Medical Education.) The total 1957 moneys distributed among the 85 schools, according to the grants formula decided upon by the Directors of the Foundation, was $984,786.83. Of this amount $480,850.00 of undesignated funds were distributed as basic grants equally among all the schools; $503,936.83 designated by donors for a specific school was distributed as an addition to the basic grant.

Letters of appreciation from the deans and university presidents of these 85 schools again pointed up the significant worth and valuable assistance of these grants. Many of these letters emphasized that the fluid nature of the gifts gave them an importance greater than the proportion they represented in the total medical school income.

State Activities and Gifts

By its very nature the American Medical Education Foundation is the sum total of the local and state activities which have been organized to further its purpose. This report cannot detail any but examples of the 51 state efforts that were responsible for 1957's successful campaign.

Methods by which these committees across the country achieved success varied from state to state. Some states carried on an intensive and extensive mailing campaign to its membership. Other states successfully organized county committees and conducted personal solicitation campaigns. In several states the elected council constituted itself as the A. M. E. F. committee to promote county participation throughout the state.

In the fall of 1957 Indiana joined California, Illinois, Utah, Arizona, and Nevada by voting to add $10.00 to the state association dues as a gift to the American Medical Education Foundation from every member of the state society. This collective arrangement has also been adopted by many of the county societies across the country. These counties cannot be enumerated here but they are growing in numbers. For example: during the first six months of 1958 eight of the county societies in Texas voted an increase in their county dues to show a 100% participation by their members.

During the 1957 year a significant growth in the number of individual contributors has occurred in a large number of states. Some of those states where the number of contributors increased most dramatically were the District of Columbia, Georgia, Kansas, Minnesota, Montana, New Mexico, Ohio, Pennsylvania, South Carolina, Texas, Washington, West Virginia, and Wyoming.

Significantly but contrary to popular expectation those states with dues increase programs also had additional substantial voluntary contributions from their members. Though this was a considerable total in California and Illinois with their large memberships, special mention should be made of Nevada which led the United States in membership participation (well over 100% because of multiple gifts from its members) and a larger per capita contributions from its members.

While on the subject of the dues increase states it should be mentioned that Illinois which first adopted the dues increase plan has in addition organized county chairmen and committees in every society early during 1958 to promote voluntary gifts from its members over and above the $20.00 dues contribution.

In 1957 New Jersey again gave the Foundation generous assistance with a check for $10,000 from the state society. In April, 1958, an additional donation of $15,000 was given with the stipulation that this was to be included as a supplemental gift for 1957 "in recognition of the honor bestowed upon the Medical Society of New Jersey in having one of its members, Doctor David B. Allman of Atlantic City, serve as President of the American Medical Association 1957-1958."

Many states, during the period covered by this report, have given generous treasury grants to the Foundation and in appreciation subsequently received Awards of Merit at the June meeting in San Francisco. The state societies receiving these Awards were Arizona, Illinois, Kansas, Massachusetts, New Jersey, South Carolina, Utah, Virginia and Iowa.

Laudatory mention is due to the following professional groups who have been consistent contributors to the Foundation since its inception and in 1957 again gave generously: Southern Medical Association; Audio-Digest Foundation; American College of Radiology; the American Society of Anesthesiologists, and Interstate Post Graduate Medical Society of America.

During the past three or four years, most of the states have decided to concentrate their campaign activity during the fall months. Despite this continuing decision, we are pleased to report that the income of the Foundation for the first half of 1958 is well ahead of the same period of 1957. With this evidence of continued strong support during a period when business has been unfavorable, it is optimistically believed that the coming campaign months will bring this year's totals to a higher point than those of previous years.

Officers and Board of Directors

The Board of Directors of the American Medical Education at its meeting in December, 1957, elected Dr. George F. Lull as President of the Foundation. Dr. F. J. L. Blasingame was elected Vice-President, and Dr. Edward L. Turner was continued as Secretary-Treasurer. Dr. Louis H. Bauer, who has held the presidency since 1953 asked that he not be renominated because of other time-consuming responsibilities. He will continue, however, as a member of the Board of Directors.

At the same time the Board of Directors proposed changes in the constitution which were adopted at a meeting on Feb. 11, 1958. These changes added four new members to the Board of Directors so that additional wisdom and influence could strengthen the Foundation's program. At this meeting on Feb. 11, 1958, four men were elected to fill these new positions. They were: Dr. Lowell T. Coggeshall, President of the Association of American Medical Colleges and Dean of the Division of Medical Sciences at the University of Chicago; Dr. Hugh H. Hussey Jr., Dean of the School of Medicine at Georgetown University and a member of the Board of Trustees of the American Medical Association; and two recent past-presidents of the A. M. A.—Dr. Dwight Murray of Napa, Calif., and Dr. Walter B. Martin of Norfolk, Va.

State Chairmen's Meeting

On Jan. 25-26 of 1958 the Seventh Annual State Chairmen's Meeting was held at the Drake Hotel in Chicago. Only a few state chairmen were unable to be present and, in addition, there were a number of metropolitan chairmen, executive secretaries, and committee men to bring attendance to 84 registered at this largest and most successful of the Chairmen's meetings yet held.

Chairmen, who came from all over the country to attend this two-day meeting, launching the 1958 campaign, were addressed by several medical educators and experts on fund raising. In addition, they had the opportunity to exchange ideas and methods that strengthened their own programs.

Total Physician Contribution to Medical Schools, 1957
(Direct Gifts by Restriction)

Restriction	Amount of Contributions	No. of Contributions
Unrestricted	$1,467,097.51	36,615
For teaching budget	48,852.55	1,260
For specific department	85,806.37	1,541
For building fund	895,946.91	5,131
For research	204,045.18	1,636
For scholarship and student aid	71,750.74	939
For library	8,810.08	357
For endowment	123,272.52	905
Others	115,018.51	1,980
Totals	$3,020,600.43	50,364
Gifts to the American Medical Education Foundation		
No restriction	$ 984,786.83	44,155
Totals	$4,005,387.26	94,519

During the meeting the state chairmen expressed themselves by resolution that grave consideration should be given to a thorough study of the future problems of financing medical education. They asked that this be considered by the American Medical Association.

The Board of Directors of the American Medical Education Foundation wishes to bring to the attention of the House of Delegates the magnificent unselfish work that these state chairmen and their volunteer committees have devoted to this program during the past few years. Not only have these men given many hours to the work of the Foundation in their societies but they have made the outstanding effort that is required for fund-raising. The success of the A. M. E. F. program can be directly attributed to them.

A. M. E. F. Alumni Appeal Relations

Over the years the American Medical Education Foundation has explored methods by which it could coordinate its efforts with that of the appeals of the alumni groups of the individual schools. Several meetings have been held in the past to discuss the problems of duplicated appeals and to develop mutual cooperation between the Foundation and these groups.

On Feb. 11, 1958, the Board of Directors of the American Medical Education Foundation met with invited representatives from the school group. These representatives were alumni secretaries and fund directors who had been actively interested in the previous explorations and had worked with the American Alumni Council in an attempt to develop the best approach to the appeal to physicians for the support of their alma mater. In addition to the alumni secretaries from the following schools: Georgetown, University of Chicago, University of Michigan, St. Louis University, University of Kansas, Harvard University, and Tulane University were the Executive Director of the American Alumni Council, the Executive Director of the Association of American Medical Colleges, and two deans from medical schools.

The Board of Directors of A. M. E. F. discussed with this representative group the possibilities of closer cooperation and the areas of misunderstanding. It was agreed that further and continued discussions could erase many of these misunderstandings. At the same time a formal proposal for a coordinated program was also considered but no decision was reached as to its practicability.

Further explorations of this nature were made at the annual meeting of the American Alumni Council in June, 1958. This meeting held at Lake Placid, New York, was attended by many alumni directors who had not previously had the opportunity of presenting the viewpoints of their respective organizations. A. M. E. F. was represented by its Associate Executive Secretary, Mr. Jay Oliver, who used the meeting primarily to describe to the participants the activities and goals of the Foundation, with the result that a greater cooperation can be expected in the future.

Direct Contributions to the Schools from Physician Alumni

Since 1952, the American Medical Education Foundation has collected the names and contributions of those physicians who gave direct to the schools as well as listing the contributors who gave through A. M. E. F. During the first five years the Foundation specified that the schools report to it only the gifts they received without restrictions. During 1956 and 1957, the schools have reported all gifts to them made by physicians. Contained in this report is a table showing these totals for 1957 and also including the A. M. E. F. income which, of course, is completely unrestricted.

The Board of Directors of the American Medical Education Foundation feels that the efforts on behalf of A. M. E. F. are largely responsible for much of the increase in direct gifts from physicians to their schools.

The Woman's Auxiliary and A. M. E. F. for the Year 1957-1958

Again this year as in previous years, members of the Woman's Auxiliary have increased their gifts to America's medical schools through A. M. E. F. This increase during 1957-1958 amounted to nearly $13,000. Total Auxiliary contributions to the Foundation for 1957-1958 were $126,366.68, including a $5,000 gift from the National Auxiliary.

Great ingenuity and hard work by Auxiliary members were directly responsible for this marked progress during 1957-1958. County Auxiliary A. M. E. F. chairmen and their committees sponsored 94 different kinds of money-raising projects on behalf of A. M. E. F. Particularly successful were the use of Sympathy Cards and In Appreciation Cards which were used when the contributor wished to make a gift to the A. M. E. F. in honor of some individual. Several states were very successful also in the sale of Christmas Cards during the fall months of 1957. The Foundation is grateful to the 28 State *Auxiliaries* and the many counties who made gifts from their treasuries to the Foundation.

This year, for the first time, contributions were received from every constituent Auxiliary. Three-fourths of the states had an increase over last year's figures; Kentucky, Louisiana, Massachusetts and Mississippi more than doubled their previous year's contributions, and one state (Mississippi) tripled its last year's amount.

At the San Francisco Meeting, the American Medical Education Foundation's Award of Merit was presented to the 10 states with the highest per capita contribution. Certificates of Achievement were given to County Auxiliaries which had contributed over $1,000 to A. M. E. F. Nineteen counties received these certificates.

A new A. M. E. F.-Woman's Auxiliary table exhibit was designed for initial showing at the National Convention. This year also, a new portfolio of materials was sent to all state and county chairmen which, among its other contents, included a new Utility Card for use along with the Sympathy and In Appreciation Cards. For the first time this year an A. M. E. F. Christmas Card printing plate was designed for use by Auxiliaries. A general mailing to each Auxiliary member was sent out before the end of the Auxiliary year and brought an increased response over a similar mailing in previous years.

The Foundation wishes to thank the members of the Woman's Auxiliary for their active interest on behalf of A. M. E. F. We are extremely grateful for again being chosen as one of the priority projects of the Auxiliary for the coming year.

Program Development Activity

In the 12 months covered by this report our staff has visited nearly every state to aid the chairmen and the committees in developing, arranging, and building their programs and campaigns. Additional efforts have been made with many individual cities to aid and strengthen their organizations.

The A. M. E. F. office also prepared material for use by the state chairmen and their committees. Promotional folders and business reply envelopes were furnished to all the states as well as other tools for use in their campaigns. More than 700 portfolios for chairmen and committee members were distributed during 1957. A new portfolio for 1958 was given to the attendants at the state chairmen's meeting and was sent to all the workers who were not able to be at this meeting as well as to county chairmen and local committee members.

In the past the Foundation had printed an elaborate annual report that was sent to all contributors and others interested in the figures and the significant achievements of the previous year. In the fall of 1957, it was decided that this could be done more effectively by changing the format of the annual report so that, for the same printing and mailing costs, it could be sent to the entire profession. This was done with gratifying results. Though no direct request was made, business reply envelopes were included with the report and more than $50,000 in contributions were returned to the Foundation in these envelopes.

This mailing was followed up by the general mailing that has been sent each year describing the tax advantages of philanthropic giving. Again the response was gratifying.

Last fall, to coincide with these national mailings many of the states mailed appeals to their members with materials furnished by the national office. The Foundation is particularly grateful to the many local publications and bulletins that made exceptions to long-standing rules by including A. M. E. F. appeal material under the same cover as the publication. The effectiveness of this mailing appeal by the states was measured by 'keyed' return envelopes, that is, business reply envelopes of different colors —and the Foundation was surprised at the effectiveness of this type of appeal.

Again, this year, the A. M. E. F. as one of the co-sponsors of Medical Education Week, assisted in its planning and programing. The A. M. E. F. office also helped the Woman's Auxiliary in the preparation of materials and in their other activities that brought public attention to the work of the medical schools.

In Appreciation

The appreciation of the Directors of the American Medical Education Foundation is most gratefully expressed to all those who have, with such zealous attachment, aided the Foundation's aims since its inception.

A wholehearted tribute to Dr. Louis H. Bauer, our President for five years, is sincerely tendered. Dr. Bauer gave freely of his time and counsel on all occasions and it is indeed the good fortune of the Foundation that Dr. Bauer remains with us on the Board of Directors.

Special recognition is herewith acknowledged for the debt owed by the Foundation to the Women's Auxiliary and its members who, in recognizing the necessity, have organized so helpfully to alleviate the medical schools' unmet needs. In particular, we wish to thank Mrs. Paul C. Craig, Immediate Past President, and Mrs. Karl F. Ritter, National A. M. E. F. Chairman for 1957-1958, who is again assuming the Chairmanship for the coming year.

The Board of Directors wish to thank again the House of Delegates, Trustees and Officers of the American Medical Association for their generous gifts, their individual help, and for the special administrative and operational allocation which permits the Foundation to give the medical schools every dollar raised in their behalf.

Additional statements of appreciation are most deservedly due the Editor and Staff of The Journal for advertising space and thoughtful assistance in the preparation and publication of editorial material concerning the objectives and progressive development of the Foundation's programs. We wish to also thank the many state, county, and city journals and newsletters which have printed many perceptive articles *urging support for the nation's medical schools through the* machinery of the Foundation. *Modern Medicine* and *Medical Economics* also deserve our appreciation for the advertising space they so cheerfully contributed to the A. M. E. F. during the past year.

The Directors of the American Medical Education Foundation must repeat their gratitude to the state and county associations, particularly the officers of these organizations, their councils and their boards of trustees who have made A. M. E. F. efforts an important part of the program of their organizations; who have given portions of their meetings to our appeal; who have written editorials, mentioned its importance in their talks, and traveled miles to attend campaign dinners and meetings. Their work has been made particularly effective by the many society executive secretaries and staffs who have also earned our gratitude by putting forth the extra effort for A. M. E. F. given ordinarily for voluntary interests.

But in the last analysis the American Medical Education Foundation reserves its deepest appreciation for those 45,000 physicians who have understood the purpose of the Foundation and, by their gifts, have made possible the progressive success of the American Medical Education Foundation.

THE INDUSTRIAL EXHIBITION

12th A. M. A. Clinical Meeting

Dec. 2-5, 1958 • Minneapolis Auditorium

The Industrial Exhibits at the Minneapolis Meeting will provide a quick review of the new developments in medicine.

The visiting physician will have an excellent opportunity to examine new ideas and new methods—as well as to review familiar products and new applications that have been developed.

From Tuesday to Friday, Dec. 2 to 5, in Minneapolis, 130 industrial exhibitors will put the newest developments in the field of medicine on parade for you. With ease and at your convenience you may pick and choose what is useful in your practice. Well-trained representatives of each company will answer your most technical questions and help in every way to make your practice of medicine more effective and efficient.

The Industrial Exhibits will be open from 8:30 a. m. to 5:30 p. m. each day of the meeting, closing Friday at 12 noon. For your convenience all features of the Minneapolis meeting are under the same roof. The Scientific Exhibits, Industrial Exhibits, Clinical Discussions, Color Television, and Medical Motion Pictures are placed within a few hundred feet from one another.

We look forward to seeing you in Minneapolis and to your making full use of the values the Industrial Exhibits offer you.

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

85th Congress

The first session of the 85th Congress convened Jan. 3, 1957. The second session adjourned in the early morning hours of Aug. 24, 1958. During these two sessions, 20,604 various legislative measures were introduced. All of these were screened for possible medical significance, and 704 were analyzed, reported and followed by the Washington Office of the American Medical Association. Of these, 10 bills were enacted into law during the first session, and 16 were enacted into law during the second session, a total of 26 out of 704.

As a comparison to show the increased interest and activity of Congress in matters pertaining to medicine, the records of Congress for the last eight years are tabulated below.

Congress	Bills Analyzed, No.	Bills Enacted into Law, No.
82nd	250	11
83rd	407	24
84th	571	25
85th	704	26

The 692 bills reported in this section on Federal Medical Legislation in various issues of The Journal during 1957 and 1958 were broadly grouped as shown in the tabulation below. (The Journal, 165:1702-1705 [Nov. 30] 1957, carries a summarization of the first session of the 85th Congress.)

	First Session	Second Session
Social security	68	52
Rehabilitation and problems of aged	66	28
Tax deductions and retirement plans	68	32
Veterans legislation	44	25
Labor, welfare, and benefit plans	26	15
Civil defense	22	3
Hospitals and other medical facilities	17	18
Military and defense measures	14	10
Federal employees	12	3
Drugs, drug addiction, and alcoholism	12	2
Medical and related education	12	13
Mosquito research and control	11	0
Food and chemical additives	10	3
Treaties and international agreements	7	0
Voluntary health measures	7	0
Pollution of air and water	4	10
Nursing	3	0
Antirecession	0	26
Miscellaneous	43	6
Total	446	246

Social Security

In this Congress, as in previous Congresses, the greatest number of bills introduced, 120, pertained to social security. Congress again amended the Social Security Act, as it has done every election year since 1950. H. R. 13549 became Public Law 85-840 on Aug. 28 in response to demands that benefits keep pace with the cost of living. To finance the liberalizations, the law increases the taxable base from $4,200 to $4,800 of gross employment earnings and raises the tax in 1959 from 2.25 to 2.5% for the employer and employee and from 3.375 to 3.75% for the self-employed. Additional increases are scheduled for 1960, 1963, 1966, and 1969. By 1969, the self-employed will be paying 6.75% of earnings up to $4,800, or $324 per year. Congress also provided an additional 197 million dollars for public assistance recipients and gave states greater flexibility in use of federal funds for financing the medical care of the aged, blind, the disabled, and dependent children.

Congress left the door ajar for consideration, by the next Congress, of bills using the social security system to provide hospital and medical care for OASDI beneficiaries. An articulate minority wanted this enacted this year via the proposal of Rep. Aime Forand (D., R. I.), the Forand Bill, but Congress decided against it. However, the House Ways and Means Committee directed the administration to make a study and report by next February on the various possibilities for financing medical care for the aged, with particular emphasis on the practicability of increasing OASDI taxes and using the money to purchase health insurance on retirements. The A. M. A. took a strong stand against using the social security system to provide medical care, viewing it as a beginning of national compulsory health insurance.

Next year undoubtedly will see the reintroduction of the Forand Bill and similar types of legislation both in the House and Senate.

Rehabilitation and Problems of Aged

Of 94 measures introduced affecting rehabilitation and the problems of the aged, only 5 became law.

Disability Freeze Extension, Public Law 85-109 (H. R. 6191).—Under this law, a new deadline of July 1, 1958, was established for disabled persons covered under social security to apply for full retroactivity under the disability freeze passed in 1954. Applications filed by July, 1958, would allow work-

---

From the Washington Office of the American Medical Association.

ers to count the full period of disability provided they were eligible for disability benefits at the time the disability was incurred. After next July 1, any period of disability established for a worker cannot begin earlier than one year before the application is filed.

Vendor Medical Payments, Public Law 85-110 (H. R. 7238).—This law is intended to resolve some problems arising out of the social security amendments of 1956 with particular reference to vendor medical payments for public assistance recipients. Under Public Law 110, states are given the choice of either (*a*) using federal funds for vendor medical payments within the $60 a month per recipient maximum or (*b*) establishing a single medical vendor payment financed by federal funds which were set by a 1956 law at one-half of $6 a month per adult and one-half of $3 per child to be matched by states. States also can continue to make direct payments to recipients for medical and subsistence expenses. This law became obsolete with enactment of the 1958 amendments to social security.

Vocational Rehabilitation Traineeships, Public Law 85-198 (S. 1971).—This measure extends from two to three years the maximum period of time over which the federal government can pay for partial financing of traineeships in physical medicine and rehabilitation. It amends the Vocational Rehabilitation Act which was expanded in the 84th Congress.

Vocational Rehabilitation Planning, Public Law 85-213 (H. R. 8429).—This amends the Vocational Rehabilitation Act by extending the time federal funds may be used for planning, preparing, and initiating expansion of programs in the states. Congress was asked to act when the July 1, 1959, deadline approached with considerable unexpended funds on hand.

White House Conference on Aging, Public Law 85-908 (H. R. 9822).—The President is instructed to call a White House Conference on Aging in January, 1961, by a measure passed late in the second session. This national meeting will bring together federal, state, and local leaders working in the field of aging. Their objective is to arrive at facts and recommendations on the utilization of skills, experiences and energies, and the improvement of the conditions of older people. A final report would be submitted to the President within 90 days after the conference. A series of state-organized meetings would precede the 1961 conference. To help the states finance these meetings, the law provides up to $15,000 a state with a minimum of $5,000. These figures, reduced from the original $50,000 per state, were used with the anticipation that states would also participate substantially in the financing. The A. M. A. gave this legislation its full support; author of the bill was Rep. John Fogarty (D., R. I.).

Tax Deductions and Retirement Plans

Of 63 measures for proposed tax deductions, 43 would give varying degrees of tax relief for expenses incurred in obtaining higher education for the taxpayer, his spouse, or his dependents; 20 bills would have allowed an increased deduction for medical expenses. No hearings were held nor action taken on any of these bills.

Of 37 measures that were introduced pertaining to retirement, the two most important to physicians were Senator Sparkman's bill S. 3194 which would have given tax relief to small business. Physicians would have qualified as small businesses. The bill which contained provisions for a retirement plan along the lines of the Keogh bill died in the Senate Finance Committee. H. R. 10, more commonly called the Jenkins-Keogh Bill, passed the House on July 29 with scarcely a voice raised in objection and was sent to Senate. This long-sought measure would allow self-employed professional or business men to set aside 10% of net earnings each year to an annual maximum of $2,500, with the tax on that amount deferred until retirement. As many as 7 million persons would benefit. The fight for passage has been spearheaded by the American Thrift Assembly, of which the A. M. A. is a member.

Representative Keogh (D., N. Y.) led the debate for passage. He stressed the bill's voluntary nature and the righting of a tax inequity. (Employers now may set aside tax free sums for employees in company retirement plans.) More than a score of Congressmen joined in urging passage; they included Representative Reed (R., N. Y.), ranking minority member of the House Ways and Means Committee and early advocate of a similar bill.

This observation on the bill's merits came from Representative Dennison (R., Ohio): "Self-employed persons generally assume large personal risks. Those in the professions . . . have a tremendous investment in time and money before entering into actual performance of their calling. They must in their productive years set aside sufficient funds to take care of themselves in the years when their own human energy and resources have been depleted. It is not unreasonable or unfair to give them the same tax benefit that employed persons enjoy."

Representative Rogers (D., Fla.) pointed out: "Company officials and employees receive benefits from retirement plans which are not counted as income until the money is actually drawn out, and the company counts their contributions to the funds as business expenses at the time they pay into the fund."

The Senate, in a 52-32 vote on a technical issue, on Aug. 12 sidetracked the Keogh bill to help the self-employed set up retirement plans. Subsequently, it was learned that Senate policy committees of both parties decided to oppose the bill at this time because of the loss of tax revenue it would cause.

However, backers of the bill will continue their efforts for favorable Senate consideration in view of the overwhelming vote for it in the House. Also, they are encouraged that 32 senators voted for the measure despite the unfavorable legislative situation and the attitude of party leaders. Many supporters are convinced that the progress made this year will pave the way for enactment in the new Congress when it meets in January.

The Senate vote developed this way: When a bill for correcting and changing many parts of the tax law came up for debate, Sen. Charles E. Potter (R., Mich.) offered the Keogh bill as an amendment. Sen. Russell Long (D., La.) and several others took the floor against the Potter amendment, complaining of the tax loss involved, of the fact it was discriminatory, and that the Senate Finance Committee had not studied the legislation.

Senator Wayne Morse (D., Ore.) then moved the adoption of a substitute for the Keogh bill that would cover all taxpayers, but with a lower set-aside limit ($1,000 annually instead of the Keogh bill's $2,500). The Morse bill would result in a tax loss of as much as 1.9 billion dollars annually, in contrast to the Keogh bill's 365 million (a treasury estimate that Keogh supporters say is too high). Morse argued that the Keogh bill was discriminatory and that all taxpayers should have the benefit or none should have it.

At this point Sen. Robert S. Kerr (D., Okla.) challenged the motions as not germane to the bill actually before the Senate. The ruling was that both were germane, whereupon Senator Kerr asked the Senate to reverse the chair's ruling. Thus the senators were left with a choice of reasons for their votes. They could vote nay because they were (*a*) against the Keogh bill, (*b*) against the Morse bill, or (*c*) did not believe either bill should be made a part of the legislation under consideration but should be handled separately and be considered by the Senate Finance Committee.

Time ran out and the bill died in the Committee. New efforts to get the measure passed in the 86th Congress are being planned.

Veterans Legislation

Of 69 measures introduced pertaining to veterans and the Veterans Administration, 3 became law. One on codification of veterans laws, Public Law 85-56 (H. R. 53), without making any substantiative changes in existing law, brought into a single code all veterans benefit laws, dealing with compensation, pension, hospitalization, and burial benefits. Some of the laws date back 30 years.

H. R. 9700 also became Public Law 85-857 and would further consolidate into one act all the laws administered by the Veterans Administration, including Public Law 85-56 enacted in the first session.

The other pertaining to pay for veterans administration physicians became Public Law 85-462 (S. 734) giving a salary increase to VA physicians. A provision that would have given VA optometrists the same professional status as physicians and dentists was dropped from the measure.

Late in the session as a windup to lengthy hearings on veterans entitlement to VA hospitalization, the House Veterans Affairs Committee reported out an omnibus hospitalization bill (H. R. 10028). The measure had as its major objective the opening of additional beds which the committee maintains the Budget Bureau is holding back on. It was reported too late for final action and died with the adjournment of Congress. The A. M. A. testified in favor of a clear spelling out by Congress of veterans entitlement to federal care.

H. R. 413, on presumption of service-connection for leprosy, and H. R. 1143, on presumption of service-connection for arthritis, psychoses, or multiple sclerosis, both passed the House but died in the Senate Committee. H. R. 1264, on pulmonary tuberculosis, declaring veterans suffering from active pulmonary tuberculosis to be permanently and totally disabled for pension purposes while hospitalized, passed the House but also died in the Senate Finance Committee with the adjournment of Congress.

Labor, Welfare, and Benefit Plans

Forty-one measures were introduced on labor, welfare, and benefit plans; most were an outgrowth of the hearings by the Senate Committee investigating the labor unions. Only one passed (S. 2888) to become Public Law 85-836 and would correct abuses in health and welfare plans. Congress, after considerable debate, voted the measure requiring both labor and management health and welfare plans to make annual financial reports to the Secretary of Labor. It exempts plans with fewer than 25 members. Fines as high as $10,000 or five years imprisonment are provided for falsification of reports.

President Eisenhower signed into law this bill providing a limited amount of publicity for union-management welfare funds (medical plans included), but at the same time he criticized the legislation as too weak and said it would be ineffective unless tightened up by the next Congress. Under this law the funds are required to register with the Secretary of Labor and make annual reports, which will be filed with the secretary and made available to any beneficiaries. In a statement Mr. Eisenhower declared:

1. The act requires only summary statements of many important aspects, "making it possible to conceal many abuses."

2. No agency of government is authorized to provide uniform interpretation of the bill's technical terms, and "the chaos that will result is obvious."

Failure to designate an agency plan administrators can consult for reliable and authentic opinions, and for report forms, "enables corrupt administrators to hide abuses, blocks beneficiaries from receiving adequate information, and subjects administrators to uncertainties in compliance."

3. The bill's reliance solely upon individual employees to compel compliance through court proceeding is most unrealistic. "Employee suits alone are inadequate as enforcements remedies. Unaided by governmental authority to conduct investigations and institute litigation, individual employees, without financial resources or legal experience, can be easily intimidated, made subject to reprisals and discouraged from taking effective action."

4. The bill fails to give the Secretary of Labor either investigatory or enforcement powers with respect to reports filed with him.

5. There is no provision for dealing directly with "the most flagrant abuses," such as embezzlement and kickbacks, once they are uncovered.

In conclusion the President said: "Not only did the Congress fail to appropriate any money to administer the custodial and other functions of the secretary under the bill, but the annual financial reports will not have to be furnished until as late as May, if the plans are on a calendar year basis or for a period of 120 days after the completion of the fiscal year if they operate on a fiscal year basis."

Civil Defense

Twenty-five measures pertaining to civil defense were introduced. Of these, H. R. 7576 pertaining to civil defense grants became Public Law 85-606 and would bolster sagging state civil defense programs. Congress voted grants to the states for purchase of radiological instruments, personal equipment for state and local civil defense workers and for administrative and personnel expenses. Amounts for the first category would not exceed 35 million dollars; for the second category, not more than 2 million; and for the third, not over 25 million.

The administration's Reorganization Plan no. 1 of 1958 submitted by the President for merging the Office of Defense Mobilization and Federal Civil Defense Administration on July 1 into the Office of Civilian and Defense Mobilization passed its final hurdle. The Senate Government Operations Committee on June 16 decided not to recommend a disapproving resolution sponsored by Senator Potter (R., Mich.). Under the Reorganization Act, any reorganizing proposal of the President automatically goes into effect after 60 days of issuance of details unless either House or Senate adopted a disapproving resolution. The House government operations subcommittee which looked into the proposal did not object but did raise some basic questions. It observed: "The plain facts of life also suggest that civil defense is in so low a state that nothing could make it worse and something could make it better."

Late in Congress a measure was introduced and passed changing the name to the Office of Defense and Civilian Mobilization.

Hospital and Other Medical Facilities

Thirty-five measures affecting hospital and other medical facilities were introduced. Of these, three were enacted into law. H. R. 8053 pertaining to Indian and Non-Indian Hospitals became Public Law 85-151 during the first session. At the urging of some Western-state members of Congress, P. L. 151 was enacted to authorize federal funds to help build nonprofit or public hospitals and diagnostic or treatment centers on or near Indian reservations; the extent of federal contribution will be determined by the percentage of care given eligible Indians. The facility sponsors have to agree to care for both Indians and non-Indians.

During the second session two amendments were added to the Hill-Burton program. H. R. 12628 became Public Law 85-664, which provided a five-year extension of the Hill-Burton hospital constructions program. In a separate action, Congress further amended the act by passing H. R. 12694 to become Public Law 85-589 to permit, for the first time, Hill-Burton loans at virtually the same rate of interest the government pays for its own borrowing. Under the loan act, an applicant would have to comply with all H-B regulations the same as regular H-B applicants. The A. M. A. testified in support of the Hill-Burton extension.

An added note is the appointment in July of Dr. Jack C. Haldeman to direct the government's multimillion-dollar Hill-Burton hospital construction program. He helped organize the program more than 12 years ago. He has been serving as deputy chief of the Public Health Service division of hospital and medical facilities. When Hill-Burton was launched in 1946, Dr. Haldeman was executive officer and had an important part in developing regulations and operating procedures and organizing the field staff. Dr. Haldeman succeeds Dr. Vane M. Hoge who has been appointed executive director of the Hospital Planning Council of Chicago.

Efforts to provide new capital for proprietary and nonproprietary nursing homes through FHA-type mortgage loan guarantees failed of passage. The provision, strongly endorsed by the A. M. A., was part of an Omnibus Housing Bill that failed to pass the House under suspension of rules, after Senate approval of S. 4035.

Military and Defense Matters

Twenty-four measures affecting the Department of Defense were introduced; of these, five became laws. H. R. 6548, the doctor draft extension bill, was enacted during the first session to become Public Law 85-62. Because the doctor draft bill was set to expire July 1, 1957, this was one of the first health measures passed by the 85th Congress. It gives Selective Service authority, until July 1, 1959 (when both this amendment and the regular draft expire), to call certain physicians up to age 35 for military service. Only those under age 35 with obligations under the regular draft and who have been deferred for any reason may be called. The Defense Department, meanwhile, says it is getting enough medical school graduates as reservists to preclude use of the new law at this time.

H. R. 2460, the military nurses incentives bill, passed during the first session to become Public Law 85-155. This was in line with earlier efforts to make careers in the military more attractive. Congress passed this law improving career prospects for military nurses by making more and higher ranks available.

H. R. 11470, the general pay raise bill for the military, became Public Law 85-422 and included the increase for physicians in the services. The law also retained the incentive pay schedule for doctors in uniform which has been in effect since 1947.

The Department of Defense Reorganization Plan, H. R. 12541, became Public Law 85-599. At the prodding of the House Armed Services Committee, the Defense Department is finally reorganizing. The number of Assistant Secretaries of Defense, which Congress felt had grown too large, was trimmed back by one. It was felt that the affected post in all likelihood would be that of Assistant Secretary for Health and Medical Affairs, which would be downgraded to that of Special Assistant. The A. M. A. fought hard to have the act make clear that this post would be saved.

As a result, early in September Defense Secretary Neil McElroy informed Dr. Frank S. Berry, Assistant Secretary of Defense for Health and Medical Affairs, that the latter's post would not be abolished under the forthcoming reorganization of the Defense Department. The decision has the concurrence of the President.

Of great importance to many physicians and military dependents was H. R. 12738 on Medicare appropriations, which became Public Law 85-724. Congress took a long hard look at the Medicare program, now nearing its second anniversary, and decided that the civilian phase of the program had to be curtailed in favor of greater use of military facilities. The House first trimmed $10,200,000 from an admittedly slim budget of $70,200,000 and then wrote into the Defense Department appropriation a section that would have prevented the services from asking for any supplemental appropriation for the entire fiscal year or using other funds. When it reached the Senate, Medicare and Defense officials joined with the American Medical Association and others in a plea for restoration of funds and elimination of the destructive section. This was accomplished through an amendment sponsored by Senator Knowland (R., Calif.). In the ensuing conference, language was written in a report which, while not having the full force of law, nonetheless directed the military to start cutting back on some aspects of civilian Medicare. To this end, the Office for Dependents Medical Care announced new restrictions effective this fall. They are aimed at higher military facilities utilization, such as requiring dependents living with sponsors to use military resources unless they are not available.

The latest information is that Medicare officials, after another look at the account books, see the possibility of a shutdown of the civilian phase of the program early in 1959. The reason is relatively simple; the 72 million dollars appropriated by Congress for the fiscal year will not be adequate. And Senate and House conferees agreed that the armed forces should not spend more than that amount. Major Gen. Paul I. Robinson, who retired this week as head of the Office for Dependents Medical Care, says one solution lies in Congress changing its mind and voting more funds after it convenes Jan. 7. Another possibility is for the Defense Department to use other funds to make up its deficit and then explain to Congress next session why its instructions could not be followed.

ODMC, in further elaborating on its new restrictions on Medicare use in civilian facilities (brought on by the belt-tightening in Congress), said the following surgical procedures would be allowed: (1) bona fide surgical emergencies which cannot be handled on an out-patient basis, e. g., perforated ulcer and intestinal obstruction; (2) acute surgical conditions in which patient is in clinical need of hospitalization without delay, e.g., acute appendicitis, strangulated hernia, and pelvic abscess; and (3) injuries of such clinical severity as to require hospitalization but only for treatment of the acute phase. Elective surgery is ruled out, including interval appendectomies, cosmetic surgery, tonsillectomies, routine hysterectomy, and uncomplicated hernias.

Federal Employees

In addition to the 12 measures on federal employees introduced the first session, 10 of which were devoted to contributory health insurance, 3 more were introduced the second session. No hearings were held on these measures.

Drugs, Drug Addiction, and Alcoholism

A total of 14 measures on drugs, drug addiction, and alcoholism were introduced. Ten dealt with various aspects of control and treatment of drug addiction, three were related to biological products and one was to establish a medical advisory committee on alcoholism. No action was taken on any of these bills.

Medical and Related Education

Twenty-five measures were introduced on medical and related education. Of these, four became law.

H. R. 6287 on the fiscal 1958 budget for the Department of Health, Education, and Welfare (which starts July 1, 1957) became Public Law 85-67. Congress voted $2,503,130,381 for all HEW programs.

The National Institutes of Health received about 21 million dollars more than the House allowed. This was agreed on after two meetings of Senate and House conferees on the Department of Health, Education, and Welfare budget. The Senate had voted 32 million dollars more than the House total of 220 million for all NIH operations, including laboratory facilities construction. But when the two sides got together, they were able to pare down Senate figures some 11 million dollars.

In another section of the budget, higher Senate amounts for two Public Health Service items remained untouched. These were grants to states for general health activities and funds for communicable diseases. Rounded off figures approved by the conferees for the various institutes in millions of dollars are tabulated below.

Institute	Millions of Dollars	
	1958	1959
General research	14.0	29.0
National cancer	56.4	75.0
Mental health	39.2	52.0
National heart	35.9	45.6
Arthritis and metabolic diseases	20.4	24.0
Neurology and blindness	21.4	29.0

H. R. 11645 pertained to the budget for the Department of Health, Education, and Welfare for the fiscal year 1959 (starting July 1, 1958) became Public Law 85-580. In response to appeals from a number of sources, the 85th Congress set a new high in money voted for the Department of Health, Education, and Welfare, particularly for the U. S. Public Health Service. The latter now is spending at the rate of close to three quarters of a billion dollars a year. Last year the PHS received from Congress approximately 562 million dollars; this year's total is $745,747,000. Members of Congress find it difficult to vote against more funds for medical research and a myriad of other health programs, once health-oriented House and Senate committees have agreed on certain figures for the ensuing year. Research money for the seven institutes was increased nearly 40% over last year, while the Hill-Burton hospital construction program received a boost of close to 55%.

Senate-House conferees agreed on a budget for the Department of Health, Education, and Welfare, including record high appropriations for the Institutes of Health.

A total of 294 million dollars for the Institutes was appropriated, or 75% more than the House had proposed; 186 million for the Hill-Burton hospital construction program in contrast to 121 million proposed by the House (diagnostic-treatment centers and chronic disease hospitals were cut from the Senate's 20 million to 7.5 million each, but Senate figures were accepted for rehabilitation centers and nursing homes—10 million each); 6.9 million to build a National Library of Medicine and 9.6 million to build an office building at NIH. Rounded off figures approved for the various institutes (in millions of dollars) are general research 29, cancer 75, mental health 52, heart disease 45.6, dental research 7.4, arthritis 31, allergy and infectious diseases 24, and neurology and blindness 29.

H. R. 11414 on Public Health School Grants became Public Law 85-544. Eleven schools of public health promised a total of 1 million dollars annually in federal grants to assist them in professional training, specialized consultative services, and technical assistance with the states. The final act was simply an authorization. Efforts were made late in the session by the Senate to add 1 million dollars to a supplemental appropriation for a number of agencies. This item was knocked out in conference, which means that funds will not be available until the next Congress acts.

H. R. 12876 on Research Facilities Extension became Public Law 85-777. Two years ago Congress voted a new program of grants to help medical schools and similar facilities doing research in various crippling and killing diseases to construct laboratories and similar buildings or to remodel existing structures. The program was to run for three years, with an annual appropriation of 30 million dollars. With a backlog of applications, the administration sought an extension for another three years. It also asked for a clarification of "multipurpose" facilities. In the process, the bill was amended in committee so that money available would have been available for both research and teaching facilities. This back-door approach to medical school aid later was dropped by the committee because it was felt that it would jeopardize passage of the simple extension. This 30 million dollars per year program will continue for three additional years.

Bills to authorize one-time grants for new and existing medical schools to build classrooms were pending in both House and Senate at adjournment. Extensive hearings were held by the House Interstate health subcommittee. No bill was reported to the floor because of (1) concern over the segregation issue, (2) a question of whether the states have exhausted all resources, and (3) a reluctance of some committee members to spend the money now. The A. M. A. supported one-time grants in its testimony.

Mosquito Research and Control

Eleven bills to provide funds for research and demonstration projects for control of mosquitoes were introduced in first session of Congress, but no hearings were held and no further action was taken.

Chemical Additives

Thirteen measures pertaining to chemical additives used in food and medicine were introduced; of these, one, H. R. 13254, became Public Law 85-929.

In an 11th hour action, the Senate passed a House-approved bill on the last day of the session which prohibits use of chemical additives in foods until their pretesting has been approved by the Food and Drug Administration. Provisions are made for appeals to federal decisions.

Treaties and International Agreements

No new measures were introduced the second session. Of the six bills introduced during the first session, hearings were held only in the Senate. These bills would have limited the effect of treaties or international agreements on state and federal laws.

Voluntary Health Insurance

No new measures on voluntary health insurance were introduced this session. On seven which had been previously introduced, no action was taken.

Air and Water Pollution

Fourteen measures on pollution of air and water were introduced—4 the first session and 10 the second. These later 10 measures dealt primarily with increased federal grants for construction of facilities under the Water Pollution Control Act.

Hearings were held on H. R. 13420 and the bill was favorably reported by the House committee. No further action was taken.

Nursing

No new measures on nursing were introduced this session in addition to the three introduced the first session. No action was taken in either session.

Antirecession

With the advent of a recession during the fall of 1957, Congress came back to the second session in January and introduced some 26 measures designed to combat the recession. The measures were primarily based on the assumption that spending more government money would stem the tide of the decline in business. Many other bills included under the headings of Hospitals and Other Medical Facilities and Medical and Related Education also had increased appropriations and features designed to combat the recession.

Of these 26 measures, 6 would have extended the length of time for unemployment compensation paid by the states, and 20 would have established an Emergency Community Facilities and Public Works Program. One of these, S. 3497, would have provided for low-interest loans to states and communities for a wide range of public works, including construction of community hospitals. After the Senate had passed this measure, the House refused to consider it.

Miscellaneous

Of the 49 miscellaneous bills introduced, 43 were introduced the first session. Of these, one became Public Law 85-172 providing for compulsory federal inspection of poultry moved in interstate commerce. The responsibility for enforcement is lodged with the Department of Agriculture.

Of the six bills introduced the second session, one would have prohibited the treating of water for human consumption with fluoride compounds by any officer of the United States, the District of Columbia, or Territories. Three dealt with the disposal of certain federal surplus property to public health agencies and states. One was an antivivisection measure prohibiting any person from transporting in interstate commerce, in the District of Columbia or Territories, cats or dogs for vivisection or medical or scientific experimentation. Another would have discontinued federal grants for vocational education and waste treatment facilities and reduced the federal excise tax on local telephone service to assist the states in assuming financial responsibility for their programs.

H. R. 4275 would have established a Civil Air Surgeon with broad authority in civilian air safety, but it failed to pass. But with creation of the Federal Aviation Agency, by Public Law 85-726 (S. 3880), administration assurances have been given that the needs of aviation medicine will be considered in setting up the new agency. The A. M. A. was a strong supporter of the idea of a Civil Air Surgeon.

COUNCIL ON NATIONAL DEFENSE

The Joint Commission on Accreditation of Hospitals requires every hospital to have a written disaster plan known to all personnel and rehearsed at least twice yearly. Hospitals have not encountered too much difficulty in preparing their written disaster plans. However, testing the adequacy of the paper plans is another matter. Because such tests would interfere with, or conceivably disrupt, their day to day functions, few hospitals have undertaken realistic tests of disaster plans.

In recognition of the need for making medical civil defense a part of the day-to-day activities, a guide for testing and rehearsal of hospital disaster plans was prepared for the Detroit Area Hospital Council to be distributed to hospitals. The following paper, based on this guide or standards, was presented by Max L. Lichter, M.D., at the Sixth National Medical Civil Defense Conference in San Francisco on June 21, 1958. The Council is hopeful that this information will be of interest and assistance to hospitals and their staffs in making medical civil defense effective. Copies of the pamphlet "Standards-Testing and Rehearsal of Hospital Disaster Plans" may be obtained by writing Mr. Jacques Cousin, Director, Greater Detroit Area Hospital Council, Inc., 1084 Penobscot Building, Detroit 26. Frank W. Barton, *Secretary.*

A YARDSTICK FOR TESTING HOSPITAL PLANS FOR DISASTER

Max L. Lichter, M.D.
and
Jacques Cousin, M.A., M.S., Detroit

Natural disasters, which in recent years have seemed to occur more frequently, have brought about an awareness by hospitals of the need to develop plans to handle large numbers of casualties. The necessity for this type of planning has been further emphasized by a growing reliance by the public that the hospital is a part of the normal security services available in the community, along with the police, fire, and health departments and the American Red Cross. The public expects hospitals to function efficiently in emergency situations. This function has been recognized by the American Hospital Association and the American Medical Association, which have urged that hospitals appoint disaster committees to develop adequate and workable disaster plans. The importance of this function has been further pointed up by the Joint Commission on Accreditation stipulating that accredited institutions must have a written disaster plan which must be tested periodically.

In this newly emphasized activity, now so important to hospitals, it is natural that many questions will arise. In this article we wish to present what we think are adequate answers concerning two aspects of this problem.

If one assumes that a disaster plan has been developed and that all staff members and hospital personnel are familiar with it and that each knows his assignment and duties, two questions usually present themselves: 1. How can the effectiveness of the plan be determined? 2. How can awareness of and familiarity with the plan be maintained?

It has been our experience that these important questions are answered only by periodic rehearsal or testing. Quite naturally this in turn raises another query: How do you go about testing the plan? To answer this an outline for rehearsal and testing of disaster plans was developed in Detroit. This has proved effective as a guide.

For our purposes a rehearsal is defined as practice, implying staging and prior knowledge on the part of all participants. A test, on the other hand, implies an element of surprise, a deliberate attempt to try the plan. While a rehearsal is the easier and more convenient educational device, a test provides a more valid and interesting result. Whether a plan is to be rehearsed or tested is a matter of choice for the hospital, since the purpose of both is the same, namely: (1) to educate hospital personnel in their role in disaster and (2) to determine the adequacy of the mechanical provisions in the planning.

In either event, rehearsal or testing, certain considerations are common to both although not necessarily to the same degree. These are (1) the parts of the plan which are basic to an adequate testing program; (2) those portions which might be tested

---

Chairman of the Committee on National Defense, Michigan State Medical Society, and a member of the Committee on Civil Defense, American Medical Association (Dr. Lichter); Executive Director and Secretary of the Greater Detroit Area Hospital Council, Inc., and a member of the Committee on National Defense, Michigan State Medical Society (Mr. Cousin).

Read before the Sixth Annual National Medical Civil Defense Conference in San Francisco on June 21, 1958.

optionally; and (3) those areas which, because of their routine or ancillary character, need not be included.

Now let us take up briefly each of these individual points. Point 1 deals with those parts which are basic to an adequate testing program. We consider the following parts to be the most vital segments of a disaster plan: (1) the ambulatory casualty post, (2) the ambulance area, (3) admissions and triage, (4) record making, and (5) emergency communications, which includes both alert procedures and disaster operation communications. These activities are the first to be triggered by disaster. The proper functioning of these areas therefore is essential to the successful operation of the entire plan.

Point 2 deals with those areas of optional consideration in a testing program which can be enumerated as follows: x-ray department, supply, information service, volunteer personnel service, and traffic control. Of these the only one not part of usual hospital operations is the volunteer personnel service. The presence of volunteers in large number can create serious traffic control and communications problems. Certainly adequate planning should be made for receiving and assigning of volunteers in accordance with their experience and capabilities.

Point 3 deals with those areas which in our opinion need not be included in a testing program because of their inherent routine characteristics. These are the laundry, engineering, housekeeping, and dietary departments. Granted, in actual disaster operation these departments do have a most important role. They could be expected to function under an added load. Beyond being involved in planning and rehearsal they do not lend themselves to testing.

Extent of Test

The extent of the test is, of course, a major consideration. Extent depends on the status of planning and the inclination of the hospital's administration and medical staff. The rehearsal or the test, as the case may be, can range from a paper exercise to the surprise unloading of simulated casualties. In a rehearsal the department heads and key personnel having responsibility relate and discuss solutions to a hypothetical problem. As a matter of fact, this should always be the first phase in any testing program.

Another method is to formulate a hypothetical situation. Sealed envelopes, to be opened at stated times, would contain information concerning the problem and changes in the situation which might be conceivably encountered in actual disaster operations. Each department head would then be expected to submit the course of action he would have taken to cope with the problem as it developed. The consideration of these reports would make an excellent subject for a critique.

A third method would be a walk-through exercise involving assigned personnel. A situation is posed to develop familiarity with assigned duties. Each of the segments of the plan as mentioned in point 1 can be rehearsed and even tested individually.

Along with this walk-through type of exercise, I would like to relate an exercise in a hospital where litters were used instead of patients. Cards outlining certain types of injury sustained were placed on these litters, and then these were taken to the various areas as though they were casualties. One interesting development was that it was found that the stairway did not permit the litters to be transported because of certain mechanical problems in the construction of stairways, but this certainly pointed out that by this very simple device that a different route for transporting casualties through those corridors had to be found.

Testing a plan segment by segment is considered adequate providing those having relationship are tested together. For example, in many plans the maintenance division will supply personnel to unload ambulances. At the same time it is generally the division which is responsible for internal traffic control. Since these assignments frequently conflict, a test of traffic control alone would not be realistic since the objective is to see how well this division will function. Another example: The use of medical records should be tested to familiarize personnel with the forms to be used and to determine the efficiency with which these can be completed. Therefore, it is advisable to test medical records in conjunction with the admission area, for the latter is the point at which records will originate. Since the admission area could be overwhelmed with patients it would be necessary to determine the facility with which medical records can be completed. It is important to avoid a bottleneck to effective triage.

One other important area of a disaster plan must be tested thoroughly. This is the alerting procedure for personnel and particularly members of the medical staff. It has been found in trials that this procedure breaks down, probably because the necessity for its rehearsal is not recognized. Without adequate personnel and medical staff serious and unwarranted delay in putting a plan into operation could result. It cannot be emphasized too strongly that this procedure be effectively rehearsed and tested periodically.

An element of surprise in a testing program is to be recommended at some time since it may uncover deficiencies in planning which might otherwise be undetected. The employment of simulated casualties together with community participation has distinct advantages. This would critically test a hospital's ability to receive, admit, and treat casualties. A certain amount of deliberate confusion, such as people seeking information, volunteers presenting themselves to help, deliberate misinformation concerning anticipated number of casualties, the unexpected arrival of a truckload of supplies, the assumption that the hospital's basement is being flooded and the power plant endangered (or already out of operation): these and similar other interpolations would lend interest and variety to the problem.

Comment

We recommend strongly, after all parts of the plan have been rehearsed and tested individually or in appropriate combination, that each hospital conduct a test of the entire plan, as it might be used under actual conditions. The public relations value of this to the community as well as to the hospital, its personnel and medical staff, would seem to be immeasurable. Publicity should be obtained to assure the community that the hospital is readying itself to function in the stress of disaster. The benefits to be derived from an all-out surprise testing of the hospital plan will more than compensate for any inconvenience and give the hospital personnel a feeling of security in knowing they are prepared to discharge the community responsibility of the hospital under the most trying circumstances. If and when disaster actually occurs, the practice will be well appreciated. The hospital disaster plan is a complicated thing and we are sure you will all concede that expecting a complicated procedure to operate smoothly without prior practice is wishful thinking.

One final comment should be made. We do not imply that all of this is simple to accomplish. A broad outline has been presented; the details will suggest themselves during implementation. We recognize that careful thought and planning must go into a testing program. But the effort will be worthwhile and gratifying because the net result will be (1) the adequacy of hospital disaster plan demonstrated, (2) weakness and deficiency corrected, (3) the plan kept alive and subjected to periodic review, and (4) efficient functioning of the hospital enhanced should a disaster actually occur.

COUNCIL ON MEDICAL SERVICE

ABSTRACTS ON ABSENCE FROM WORK AND ITS RELATION TO PRIVATE PRACTICE

Studies have shown that, of all absences from work attributed to illness and injury, about 90% are due to nonoccupational illness and injury. The role of the private physician in finding and certifying health conditions justifying absence and in returning his patient to work at the earliest opportunity is therefore a most important one. This is emphasized by the fact that perhaps no more than 25% of the total work force is employed in establishments which have in-plant medical programs.

The family physician comes in contact with his patient as an individual; the company for which the patient works as an employee comes in close contact with him both as an individual and as a member of a group. In this latter relationship he may be one of a group within a certain department, engaged in a particular occupation, or belong to a specific age group. Company experiences with causes of work absence on management and medical levels have resulted in the accumulation of different types of data as well as the formulation of theories as to factors which cause, or contribute to, absence from work due to sickness.

Concern with the problem is universal.

The worker is the focus of our attention.

But, management, labor, and the economy are also affected. . .

As is the physician in industry.

And, not least of all, the family physician.

"Absenteeism," "absence from work," "work absence," "absentism," and "presentism" are among the terms which have been used to identify the problem.

Attempts to define the problem have resulted in a reappraisal of the concept of health status and the causes of work absence.

A better understanding of work absence involves accurate and detailed record-keeping.

It also involves the adoption of uniform definitions and formulas for computing work absence data.

It is from such data that we are able to add to our knowledge and understanding of the problem.

Disease and injury are causes of sickness absence, but there are factors which are related to, or influence, absence.

The physician in industry alone cannot cope with the total problem.

A teamwork approach is necessary.

Members of the Committee on Medical Care for Industrial Workers are Drs. F. J. Holroyd, Chairman, Princeton, W. Va.; T. J. Danaher, Torrington, Conn.; E. P. Jordan, Charlottesville, Va.; L. Price, New York; W. A. Sawyer, Rochester, N. Y.; F. W. Slobe, Chicago; C. C. Sparks, Ashland, Ky.; D. A. Dukelow, Consultant, Chicago; Mr. E. J. Holman, Consultant, Chicago; Dr. B. D. Holland, Secretary, Council on Industrial Health; Mr. G. W. Cooley, Secretary, Council on Medical Service, and Mr. M. Klutch, Research Associate, Chicago.

In essence, then, the practicing physician assumes a central role in the development of any program related to work absence. The failure of the private physician to participate in efforts by industry to evaluate absence from work may only result in unsatisfactory programs for all concerned.

The Committee on Medical Care for Industrial Workers of the Council on Medical Service and the Council on Industrial Health has assembled a number of statements from various sources which reflect some of the current thinking and opinions held on various aspects of the problems of work absence. These abstracts are not intended to represent an exhaustive recording of views on this subject. They represent, rather, expressions of opinion which have appeared in recent literature and discussions and which should be of interest to all physicians.

The Committee has published a bibliography on work absence and the proceedings of a conference devoted to this field of interest. It has recently completed a "Preliminary Guide for Measuring Work Absence due to Illness and Injury," which will be printed in a future issue of The Journal.

Concern with the Problem Is Universal

"The subject of work absence among the employed population has occasioned considerable concern in medical, management, labor, and government circles, and in various community organizations. Over the years, an appreciable body of literature has been developed in the United States dealing with medical, economic, and sociological aspects of the problem." [1]

The Worker Is the Focus of Our Attention

"During the period, July-September, 1957, an estimated 662.8 million person-days of restricted activity due to illness or injury occurred. The total number of days lost from work because of illness was 126.8 million person-days in the quarter, or an annualized rate of 7.9 work-loss days per employed person per year . . . women missed work at the rate of 9.0 days per worker per year while men missed work at the rate of 7.4 days per worker per year." [2]

But, Management, Labor, the Economy Are Also Affected

"The problem . . . is not the concern obviously of any one group. It is, of course, of very vital concern to the medical profession. It is also of concern to the more than fifty million wage earners who support and make possible our national economy. . . . Absenteeism is a real problem to management in terms of cost in days and dollars of lost production. This cost is actually borne by the worker, by the consumer, and by the investor in the enterprise. Absenteeism is also of concern to management in terms of management's social obligations; concern with the individual employee's health, and a concern with the health of the employee population as a whole. It is also a concern of management because of the need we have of giving people the kinds of jobs, and the kind of job satisfaction, that they more and more require if our system is to progress, or even to survive. . . . The average absence rate, if there is such a reliable figure will be about 4 per cent of the total time that is scheduled for work. Translating this into numbers of people across the nation . . . we find that on an annual basis, there would be a production time loss of four hundred fifty-two million man days. . . . Work stoppages accounted for only twenty-two million six hundred thousand man days." [3]

"A worker's absence because of illness or injury is a general concern to labor in many ways. . . . Unions are not indifferent to the effect of absence on productivity. Labor is especially sensitive to the health of the economy and, both for practical and humanitarian reasons, wants to reclaim the losses represented by needless disability and unmet rehabilitation needs. . . . During World War II, labor joined with management to combat absences of all types. An awareness of the importance of maintaining production for national security has persisted in the 'cold-war' years.

"On a given day at least two million members of the American labor force are disabled because of illness or injury. The average worker loses seven and a half days of work in a year in temporary disabilities. The aggregate wage loss on the order of $10 billion still ignores the multiplier effect under which a given volume of absence may have a several-fold impact on production through impaired efficiency, personnel shuffling, idle equipment and the like. When the wage losses resulting from partial and from severe permanent disability are also taken into account, the loss to the economy has been estimated to be as great as one-eighth to one-fifth of the entire national income." [3]

As Is the Physician in Industry

"References to the extraordinary excess of days lost from sickness when compared with those lost from occupational diseases and injuries have repeatedly appeared in the literature. Moreover the number of days lost annually from sickness has been frequently converted into a sizable number of tanks, guns, planes, and ships. In short the problem of immediate concern is one of prevention and control. The industrial physician, therefore, finds himself confronted with the responsibility of determining where, when, and under what conditions ill health is occurring."[4]

And, Not Least of All, the Family Physician

"In all of this . . . you can readily see that the role of the private physician, and the diagnoses he makes, are paramount, since about 90 per cent of the time lost is on account of non-occupational disease and injury."[3]

"Absenteeism," "Absence from Work," "Work Absence," "Absentism," and "Presentism" Are Among the Terms Which Have Been Used to Identify the Problem, but . . .

"The concept of 'absenteeism' needs broadening. The word itself is defective. *It is a cousin to 'accident-proneness.'* It denotes a disposition to being absent and this makes a trait of what may in effect be a great variety of different disabling conditions. Perhaps the time has come to retire this word, which is technically inappropriate except within its much smaller, rigorous meaning. Its fatal weakness is that its sole criterion is attendance and that it fails to distinguish those days when the employee should be absent."[3]

"Absenteeism apparently has a bad moral connotation. And yet there are absences that represent desirable leaves—sort of investments in better personnel relations; improved production; prevention of prolonged costly absences and the loss of key personnel."[5]

"We have spent considerable time analyzing the apparent causes of sickness absenteeism. We were surprised to find that sickness absenteeism was not necessarily the result of disease."[3]

Attempts to Define the Problem Have Resulted in a Reappraisal of the Concept of Health Status and the Causes of Work Absence

"A worker on the job must be both willing and able to be there; if one of these conditions is not satisfied, he will be absent."[6]

"If a worker fails to be present on the job, the chances are that both he and his associates will attribute his absence to sickness. It is true, however, that *the worker's conclusion that he is unable to* work may have been influenced, consciously or subconsciously, by a number of considerations not directly related to health in the usual sense of the word. Frequent absences are inevitable unless the worker has both the will and the physical ability to work."[7]

"The true health status of the worker is obviously a primary consideration. While this may be so obvious as to seem trite, the statement is almost without meaning. Many workers with rather serious health problems may have perfect work attendance, while others seemingly in robust health may have considerable and even excessive 'sickness' absenteeism. Some of the apparent disparity arises from our limited concepts of health and disease."[7]

A Better Understanding of Work Absence

"Starts with accurate and detailed record-keeping."[8]

"Because of the importance of the problem of sickness among industrial workers, the difficulties surrounding its investigation should not discourage the collection of data and any attempts that might be made in their analysis. The pertinent data therefore should be uniformly recorded, carefully analyzed, and interpreted with caution."[3]

"There appears to be no single definition of an absence that is generally acceptable, since absence records are maintained for various purposes, and each company collecting these data presumably selects a definition that best fits its needs."[3]

"Since the problem is concentrated in a relatively small segment of the employee population, the first and obvious step is to identify this group. Record keeping is a basic requirement. Depending upon the size of the employee population and the available personnel, one might review the 5, 3 or 1 per cent of workers with the poorest work attendance. This should be done on a departmental, section, or craft basis at first so that variations in the prevalence of absenteeism within the plant may be apparent. In this way, attention can be directed toward the possibility that group factors, such as improper supervision, public health problems, and job hazards, are influencing work attendance adversely."[7]

"In order that such statistical data may be comparable from one industry to another, uniform methods of recording and tabulating are essential. Although, for certain purposes, industry may require quite detailed medical records, records of morbidity absences need be neither extensive nor complex.

"Industry should be able to obtain data on morbidtiy absences in terms of persons absent, the numbers of absences, and the amount of lost time, all by sex and age group, with division of these into *disease and injury (alternatively sickness and accident)*, and a breakdown showing occupational absences, in both categories. It should be possible to examine these data in relation to the age and sex composition of the population at risk, for total morbidity and for various causes, with the computation of appropriate rates or indices. Studies of repeat illnesses, occupational variations, and other aspects should generally be made the subject of special enquiry, because they multiply the time of recording the analysis beyond that required to produce the essentials, and require additional data on company population."[3]

It Also Involves the Adoption of Uniform Definitions and Formulas for Computing Work Absence Data

"The difficulties connected with the drawing of sound conclusions from sickness absenteeism data have perhaps been sufficiently emphasized. Attention, however, should also be directed to the matter of cause and the onset of illness, both of which may be frequently outside of employment and unrelated to it. Moreover, the diagnosis may be at times equally uncertain."[4]

"An employee absent from work should be considered to be on 'sick absence' when the reason for absence is his or her own illness or injury. The total duration of such an absence is to be considered as 'sick absence' and recorded accordingly. The practice is to be discouraged of giving to an absence, which by this definition is sick absence, some such label as 'annual leave,' 'administrative leave,' or 'leave without pay,' after the absence has exceeded a specified number of days, in order thereby to avoid the recording of this as a sick absence. Maternity leave should not be classified as sick absence, except when complications increase the normal maternity leave."[1]

"Severity rate, frequency rate, and disability rate, are the three measures which have been selected to promote uniformity in the collection, recording, and interpretation of sick absence statistics. Although other measures are in use and utilized for different purposes and reasons by various companies, the use of these three measures is recommended as standard practice. The Committee [on Medical Care for Industrial Workers] further recommends, for denoting duration of absence, the use of 'calendar days. . . .'"[1]

"The frequency, severity and disability rates chosen as sickness absenteeism indices, are defined as follows: The frequency rate is the average annual number of absences per thousand workers. The severity rate is the average number of days lost per absence, while the disability rate is the average number of days lost per worker per year. If you have any two of these rates, you can calculate the third."[3]

It Is from Such Data That We Are Able to Add to Our Knowledge and Understanding of Various Aspects of the Problem

"Absenteeism among the older workers from 55-65 years of age is less frequent because of illness than among the younger age group of 20-40 years. These statistics were gathered during years of full employment, when large numbers of older workers were on the job. They were apt, however, to stay out longer with an illness, than the younger person, because the speed of recuperation was slower. It was also noted that visits to the plant health centers for colds, headache and gastro-intestinal upsets were fewer. The older worker shows a much greater willingness and zeal to stay on the job. He may have slowed up a bit, so that his daily output may not be so great, but he is more apt to be there every day to fulfill his obligation to his employer. He is holding up his end of work as far as absenteeism, accidents and various disabilities are concerned. It would seem, therefore, that some of the prejudice against the older worker is not based on fact."[3]

Disease and Injury Are Causes of Sickness Absence, but There Are Factors Which Are Related to, or Which Influence, Absence

"Absenteeism cannot be eliminated. A certain amount of absenteeism is inevitable, and a certain amount of absenteeism can be used profitably in the interest of the health of employees. During the year of 1954, at least 25 per cent of our long term absences (that is once a week or more), were the result of our doctors' recommendations. The doctors found things wrong with employees that they didn't know were wrong with them, and sent them out for treatment. The Medical Department willfully contributed 25 per cent of the long term absence by doing that."[3]

"Factors related to absence are 'Time of day or shift; Day of week; Month of year; Year-to-year changes; Age, sex, and marital status of employees; Income of employees; Length of service of employees; Type of work done by employees; Type of operation performed by firm; Geographic location of firm, and Personnel practices of firm.'"[6]

"Factors Influencing Sickness Absenteeism

A. Intrinsic, i. e., within the worker
  1. *Health status*
    a. *Physical*
    b. Emotional
    c. Social
  2. Adjustment to job
    a. Innate ability or intelligence
    b. Education and/or training
    c. Proper assignment

B. Extrinsic, i. e., the worker's environment
  1. Biological environment
    a. Supervisor
    b. Associates on the job
    c. Family
    d. Union officers, club associates, church associates, etc.

The Physician in Industry Alone Cannot Cope with the Total Problem

"You will note that only the first or second of some 14 causes are strictly speaking in the realm of the doctor. The others are more closely related to problems of social, economic and other types of adjustment to the environment."[3]

"Whenever the physician in industry abandons his role of consultant, and assumes line responsibility for the administration or control of benefit programs, he loses his usefulness to management, and jeopardizes his unique and valuable relationship to the employees of the company."[3]

"The function of the medical department assumes a dual role: one, towards obtaining a low 'illness rate' for organic illness or serious mental illness; the other, towards helping management reduce the 'absence rate' that is due to reasons other than organic illness. But note here that I emphasize the phrase 'helping management' when it comes to reducing non-illness absenteeism."[3]

"It's human nature to feel that it's not smart to admit traffic accidents or traffic law violations to an employer. I know that many reports of an illness at home, or a bad cold or injury suffered in the 'do-it-yourself' workshop conceal a traffic injury, accident or a traffic ticket. Any person experienced in personnel will know the proportion of these is probably substantial."[10]

A Teamwork Approach Is Necessary

"Any intelligent approach to sickness absenteeism, any effective approach to sickness absenteeism, has to be by a team of people. The doctor alone cannot cope effectively with the problem."[3]

"The reduction of total absenteeism must be a function of management, whether the origin of such absenteeism be emotional, physical, or due to extraneous causes such as the opening of the baseball season or the celebration of a birthday.

"Over the last hundred years management has developed a keen appreciation, an intuitive appreciation, of the causes of total absenteeism. It has, through the very nature and essence of its activity, begun to develop, in order to survive, aptitudes and skills in its relations with employees. In direct proportion to the degree that it succeeds or fails in this sphere, so it succeeds or fails as management *per se*.

"The absenteeism rate in any enterprise is in direct proportion to the degree of efficiency of the management, and these rates differ in accordance with the policies of individual management."[3]

"The responsible supervisor will keep adequate attendance records and will review them frequently. He will note all instances of repeated absence of short duration, and absences occurring immediately prior to, or after, holidays and days off. Distinct absence patterns revealed by such records indicate the presence of a problem, and definite steps should be taken toward a constructive solution. Dr. L. J. Wade of Esso Standard Oil Company has reported that 'in many instances excessive or abnormal sickness absenteeism is only one of many evidences available to supervisors that a worker is not properly assigned or is incapable of adjustment to the demands of industry or other productive employment.'

"Dr. Wade's study included sharts showing sickness absenteeism rates in two departments at a single company location during a one-year period. As he points out, 'These charts are alike in that the percentages of workers in the particular department with absences ranging from none to six or more are represented by individual bars. Chart 1 is a beautiful example of a normal absenteeism experience. Most employees were not absent at all, while none were absent more than four times. Contrast this picture with that in Chart 2 where 75% of the employees were absent one or more times, several as many as six times during the year. Why should there be such a striking variation from one department to another when employees are working for the same management, at the same location, ostensibly under similar working conditions? There may be a number of factors, but I am convinced that there is none with which a good supervisor could not cope. I am inclined to believe that morale factors are of extreme importance.' "[9]

"This survey was made by getting the employee's attitudes, through interview and questionnaire, about all job aspects and then checking group absence rates to determine what correlations were present.

"I picked out just a few of the factors that, according to our studies, affect the group attendance on the job. One of them is the matter of job responsibility. The employees were asked in this particular situation whether or not they felt they had an adequate amount of responsibility, whether or not they could assume more, and they answered in varying degrees, of course.

"On the matter of job responsibility, we found that, of the people who had only one absence in a six-month period, 62 per cent indicated they had a sufficient amount of responsibility. At the other end of the scale the people who had more than four absences in a six-month period—only 35 per cent of them indicated that they felt they had an adequate amount of responsibility. All of the other factors follow this general trend. . . .

"These are just indicators of the correlation between employee attitudes about their jobs and their attendance on the job. This kind of relationship held true for other factors, such as whether or not an employee feels free to discuss personal probems with his supervisor. It also holds true for whether he feels he is a member of the group, whether there is team spirit in his work group, or whether he feels he is rejected and is an outside person in that situation. It also holds true as to whether he feels the company is utilizing his skills to his best advantage; and it also holds true for such factors as his feeling about his opportunities for promotion."[3]

"The specific events underlying an absence are usually commonplace and correspond most closely to a 'reason' for it. However, events or potential 'reasons' of one particular kind, or class, may occur more often in some groups than others, e. g., in groups with differing family responsibilities; they may also be associated more with some times of the day or days of the week, than with others.

"One step toward understanding, predicting, and coping with absence lies in discovering such associations. Of the more general factors, the problem is to find the most important in determining how strongly the individual will strive to maintain full attendance at work. The evidence . . . suggests that wage level may be one such factor. Family responsibilities may also act in this way but, in addition, it seems likely that the question of whether to go absent or not occurs more frequently in some family responsibility groups than in others."[11]

"True reduction in total absenteeism will occur when together, management, labor and industrial medicine allocate to the industrial medical service its proper functions of illness prevention and counselling service, and so enable it to help the worker achieve and maintain the highest level of physical and emotional well-being."[3]

"I would also like to stress the need of greater cooperation between the industrial physician and the general practitioner in the community."[3]

Conclusions

The foregoing quotations reflect some of the elements which enter into a consideration of the problem of absence from work, and with which the family physician should be acquainted. An awareness of them will assist in a clearer understanding of the causes of such absence, in the ultimate compilation of data which will accurately reflect true sickness statistics, and in the development of programs in which all physicians may cooperate.

MEDICAL NEWS

ARIZONA

Agreement on Proposed Medical School.—Following a special meeting of the council of the Arizona Medical Association, spokesmen for the association and for physicians working with the citizens committee for an Arizona state medical school arrived at the following agreement: (1) The physicians of Arizona strongly support establishing a medical school in Arizona; (2) The contribution and interest of all groups is welcome; (3) The most practical way to hasten the establishment of a medical school in Arizona appears to be to support the approach proposed by the board of regents. (The regents have committed themselves to hire qualified experts to study the questions and supply the answers necessary to proceed.)

The Arizona Medical Association emphasized that it will take no stand on the location of a school and merely hopes that when a location has been determined, all gifts will be given without restriction. The association voted an initial $1,000 to hasten the study needed for the establishment of a medical school in Arizona.

GEORGIA

Meeting of Allergists in Atlanta.—The 13th annual meeting of the Southeastern Allergy Association will be at the Heart of Atlanta Motel, Atlanta, October 31-November 1. Among others, Dr. Merle W. Moore of Portland, Oregon, president of the American College of Allergists, will discuss "Clinical Evaluation of Stock Vaccine in the Treatment of Bronchial Asthma". Dr. Oscar Swineford, Jr., Charlottesville, Virginia; "Basic Information on Desensitization"; Dr. C. Raymond Arp, Atlanta, "Histamine Therapy of Drug Reactions"; Dr. Walker Lee Rucks, Memphis, Tennessee, "Bronchiolitis—Diagnosis and Treatment"; Dr. Woods A. Howard, Lakeland, Florida, "Use of the Rare Food Diet in Diagnosis of Chronic Urticaria", and Dr. Austin T. Hyde, Jr., Rutherfordton, North Carolina, "Emotions in Asthma".

ILLINOIS

Lecture on Emotional Forces in the Family.—The second lecture in the annual North Shore Hospital lecture series will be held at the hospital at 225 Sheridan Road, Winnetka, November 5, at 8:00 P. M. Dr. Lucie N. Jessner, professor of psychiatry, University of North Carolina School of Medicine, Chapel Hill, will speak on "The Role of the Mother in the Family". The American Academy of General Practice has approved these lectures for category II credit. Physicians and allied professional personnel are invited.

Illinois Alumni Seminar Day.—University of Illinois Medical Alumni Seminar Day will be held on the Chicago Professional Colleges campus November 22, to which all alumni of the College of Medicine are invited. There will be a panel discussion on "Blood Transfusions and Laboratory Aids in the Diagnosis of Medical Problems", followed by a question and answer period, then a panel discussion on recent advances in surgery, and seminars in the departments of medicine, surgery, pediatrics and obstetrics and gynecology. The program chairman is Dr. Louis R. Limarzi, associate professor of medicine.

State Psychiatric Institute Appointments.—Dr. Otto L. Bettag, director, Illinois Department of Public Welfare, has appointed the following to constitute the Advisory Body of the Illinois State Psychiatric Institute: Dr. Francis J. Gerty, Dr. C. Knight Aldrich, Dr. Benjamin Boshes, Dr. Harry H. Garner, Dr. Roy R. Grinker, Dr. John J. Madden, and Dr. Gerhart J. Piers. This Advisory Body has approved the following appointments: Dr. Lester H. Rudy, superintendent; Dr. Percival Bailey, director of research, and Dr. Jules H. Masserman, director of education. The institute, a 400-bed neuropsychiatric hospital, will provide facilities for diagnostic and therapeutic services, for undergraduate and postgraduate training and for investigations in neuropsychiatry. Those interested in joining its staff or in opportunities for resident or other training beginning in 1959 may write Dr. Rudy, ℅ Institute for Juvenile Research, 907 S. Wolcott Ave., Room 228, Chicago 12.

Chicago

Study on Chemistry of Brain.—A five-year grant estimated at $225,000 for studies on the chemistry of the brain has been awarded to Dr. Alexander Geiger, professor of neurophysiology, University of Illinois College of Medicine, who has received the first installment of $45,000. The award was made by the National Institute of Neurological Diseases and Blindness, a division of the U. S. Public Health Service.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Society News.—The Chicago Society of Allergy has elected the following officers for the coming year: president, Harold C. Wagner, M.D.; president-elect, Israel A. Fond, M.D.; and secretary-treasurer, Bert B. Schoenkerman, M.D.——The Chicago Society of Internal Medicine has elected the following officers: president, Dr. Ernest G. McEwen (Evanston); vice-president, Dr. Wright R. Adams; and secretary-treasurer, Dr. Franklin A. Kyser, (Evanston).

Dr. Van Dellen Receives Award.—At its annual meeting in September in Chicago, the American Medical Writers' Association gave its 1958 distinguished service award to Dr. Theodore R. Van Dellen, assistant dean of Northwestern University Medical School; associate editor of the Illinois Medical Journal, and health editor of the Chicago Daily Tribune. The award is given annually to a fellow of the American Medical Writers' Association who has made distinguished contributions to medical literature or rendered unusual and distinguished service in the medical profession.

Personal.—Dr. Robert D. Moore, who, for the past 10 years has been in private practice in Kankakee, Illinois, and South Bend, Indiana, has been named associate professor of orthopedic surgery at the University of Chicago. From 1941 to 1948 Dr. Moore was on the staff of the university as research assistant, instructor, and then assistant professor. ——Dr. Eleanor M. Humphreys, professor of pathology and head of the surgical pathology laboratory at the University of Chicago's Medical Center, retired from the University September 30 after 35 years service.

KENTUCKY

Faculty Members Appointed at the University.—William H. Knisely, Ph.D., associate professor of anatomy and assistant professor of medicine, Duke University Medical School, Durham, North Carolina, has been appointed chairman of the department of anatomy at the University of Kentucky's new medical school and George W. Schwert, Jr., Ph.D., professor of biochemistry at Duke University has been appointed head of the biochemistry department at the University of Kentucky's medical school effective next July.

MARYLAND

Layman Honored by Medical Fraternity.—The Phi Lambda Kappa Medical Fraternity has established an award "to be conferred annually upon that nonphysician who has made an outstanding contribution in the interest of medicine." Mr. Jacob Blaustein, of Baltimore, was selected to be the first recipient "because his meritorious accomplishments in the furtherance of humanitarianism have extended over into, and have so richly benefited, the Cause of Medicine." The award was made Oct. 4 at a banquet. Mr. Blaustein is a former president of the Associated Jewish Charities of Baltimore (among the constituents of which is the Sinai Hospital); and a director of the Commission on Health Careers.

MASSACHUSETTS

Traineeships in Child Psychiatry.—The Walter E. Fernald State School, Waverley, has two traineeships in child psychiatry under the Training and Standards Branch, National Institute of Mental Health, Bethesda, Md., for physicians who want to complete their psychiatric education by spending a year in training in a school for the mentally retarded. The training is accredited for future diplomates of the Board of Psychiatry and Neurology. Applicants should write to: Dr. Clemens E. Benda, Director of Psychiatry and Research, Walter E. Fernald State School, Box C, Waverley 78, Mass.

MICHIGAN

Grants to Wayne University.—Gifts and grants of more than $693,700 were accepted by the Wayne State University Board of Governors at its September meeting. The largest amount, $516,207, came from the U. S. Public Health Service, National Institutes of Health, and is made up of 28 different grants for research at the Colleges of Medicine, Liberal Arts, Nursing, Education and at the School of Social Work. The American Cancer Society has also allocated $46,303 to continue studies of experimental pulmonary cancer in animals at the College of Medicine. Another $36,666 institutional research grant from the American Cancer Society is to be administered by a University-wide cancer committee. The U. S. Office of Vocational Rehabilitation has given two grants totaling $56,214 to continue traineeships in rehabilitation counseling and occupational therapy in the College of Education.

Annual Postgraduate Clinic in Detroit.—The 12th annual fall postgraduate clinic will be held at the Sheraton-Cadillac Hotel, Detroit, November 12-13, sponsored by the Michigan Academy of General Practice and the Wayne County Academy of General Practice, with the program approved by the councils of the Wayne County Medical Society and the Michigan State Medical Society. There will be symposiums on "Newer Medications", "Pediatrics", "Practical Therapeutics", and "General Medicine". There will be panels on "Psychiatry", "Cardio Vascular Disorders", "Mental Health", and "Urology". Both symposiums and panels will include speeches by outstanding investigators from various other cities. There will be scientific and technical exhibits, a congress of delegates, and a social program Wednesday evening, including a reception and banquet.

MINNESOTA

Dr. Mayo Receives Writers' Award.—At its annual meeting in Chicago in September, the American Writers' Association gave its 1958 honor award to Dr. Charles W. Mayo of Rochester, Minnesota. The citation read in part: "Your interest in education is reflected in your position as a regent of the University of Minnesota and as a trustee of both the University of Pennsylvania and Carleton College. Second to none of these achievements are your accomplishments as a medical writer and editor."

NEBRASKA

Hospital Grant.—A March of Dimes grant of $56,975 has been made for the support during the coming year of the Poliomyelitis Respiratory and Rehabilitation Center at Creighton Memorial-St. Joseph's Hospital. Medical director of the center is Dr. Harold N. Neu.

NEW YORK

Medical Economics Meeting in Buffalo.—The Erie County Medical Society, in cooperation with The Wm. S. Merrell Company, will sponsor an all-day meeting on medical economics at the Hotel Statler-Hilton, November 6. Dr. Max Cheplove, Buffalo, N. Y., president of the Erie County Medical Society, said that the three general subjects for discussion will be "The Doctor and His Office—Improving his human relationships and his business management"; The Doctor and the Law—Protecting himself against professional liability suits and planning his tax program"; and "The Doctor and His Life Planning—Selecting his investments, insurance, and planning his estate". The announcement states that 8 experts will present papers. At the luncheon, Dr. Arthur D. Kelly, Toronto, Canada, executive secretary of the Canadian Medical Association, will speak on economic problems in hospital care confronting Canadian medicine. This meeting is said to be an outgrowth of the pioneering medico-legal film series produced by the American Medical Association's law department in cooperation with the Wm. S. Merrell Company.

New York City

Reiss Memorial Lecture.—The New York Institute of Clinical Oral Pathology will present the 7th Herman L. Reiss memorial lecture at the New York Academy of Medicine, 2 East 103rd Street, October 27 at 8:30 P. M. The speaker will be Seymour J. Kreshover, M.D., D.D.S, of the National Institutes of Health, Bethesda, Maryland, on "Prenatal Factors in Oral Pathologic Conditions". Members of the medical and allied professions are invited.

Personal.—Dr. Lawrence Michael Drennan Jr., has been appointed medical director of the United Fruit Company and will move to New Orleans, since the company's medical department headquarters will be transferred there from New York. He succeeds Dr. Edward I. Salisbury, who is retiring after 32 years' service with United Fruit.——Dr. Chester A. Swinyard, former medical director of the Rehabilitation Center at the University of Utah College of Medicine in Salt Lake City, has been appointed associate director of the Children's Division of New York University.

OHIO

Health Museum Scholarships.—The Cleveland Health Museum has announced that Christian S. Nakama, executive director, Hawaii Cancer Society, is the 1958 winner of the Lester Taylor M.D. scholarship. Dr. Taylor was one of the founders of the Cleveland Health Museum and a past president of the Academy of Medicine of Cleveland. Applications for the 1959 fellowship, which carries a $500 stipend, should be addressed to Dr. Bruno Gebhard, Cleveland Health Museum, 8911 Euclid Ave., Cleveland 6, Ohio.

OREGON

State Medical Election.—The Oregon State Medical Society at its annual meeting in Portland, Sept. 3-4-5, elected Dr. Louis J. Feves, a general practitioner of Pendleton, president-elect; Dr. Verner V. Lindgren, Portland, vice-president; Dr. Max H. Parrott, Portland, secretary-treasurer, and Dr. Blair J. Henningsgaard, Astoria, speaker of the house, reelected. Doctors Archie O. Pitman of Hillsboro and Dr. John G. P. Cleland, Oregon City, were reelected delegate and alternate delegate, respectively, to the American Medical Association. Dr. Herman A. Dickel, Portland, was installed as president for the ensuing year. The society's "Oregon Doctor of the Year" award was presented to Dr. DeNorval Unthank, Portland. The next annual meeting will be in Medford, Sept. 23-25, 1959.

PENNSYLVANIA

Philadelphia

Lectures on Drug Evaluation.—A series of lectures and discussions on the second Tuesday of the month, from October to May, from 7:30 to 9 p. m., will be held at the Philadelphia College of Pharmacy and Science, 43rd St., and Kingsessing Ave., in West Philadelphia. No registration or attendance charges will be made. The program is as follows: Nov. 11—Evaluation of Antihypertensives, Robert A. Maxwell, Ph.D., Ciba Pharmaceutical Products. Dec. 9—Evaluation of Diuretic Drugs, Dr. Karl H. Beyer and John E. Baer, Ph.D., Merck Sharp & Dohme. Jan. 13—Evaluation of Analgesic Drugs, Eaden F. Keith, Hoffman-La Roche, Inc. Feb. 10—Evaluation of Drugs Affecting Neuromuscular Transmission, Dr. William A. Davis, Wallace Laboratories. March 10—Evaluation of Drugs Intended for the Treatment of Hyperlipemia, Dr. Joseph Seifter, Wyeth Laboratories. April 14–Evaluation of Anti-Inflammatory Steroids, Preston Perlman, Ph.D., Schering Corporation. May 12–Cytological Methods in Drug Evaluation, James C. Lewis, Ph.D., Philadelphia, National Drug Company.

WEST VIRGINIA

Hospital Conference.–There will be a one-day radiology conference at Man Memorial Hospital, Man, Nov. 7. Dr. Benjamin Felson, director, department of radiology, Cincinnati General Hospital, will be the guest speaker. The program will begin at 9:30 a. m. and will cover items of interest to general practitioners as well as radiologists. All interested physicians are invited.

Personal.–Dr. Ralph H. Nestmann, of Charleston, has been elected president of the West Virginia Tuberculosis and Health Association, succeeding Mr. Oscar J. Andre, of Clarksburg.—–Dr. Mildred Mitchell-Bateman has been appointed superintendent of the Lakin State Hospital to succeed Dr. Simon O. Johnson, who resigned last May. Dr. Mitchell-Bateman is a diplomate of the American Board of Psychiatry and Neurology.—–Dr. Frank A. Carone, of Morgantown, has been awarded a fellowship for heart research study at the University of London by the Life Insurance Medical Research Foundation. Dr. Carone was the recipient of this same award for 1957. In London, he will work with pathologist, Sir Gordon R. Cameron.

Annual Seminar at Bluefield.–The 6th annual medical seminar, sponsored by the Bluefield Sanitarium, Stevens Clinic and Clinch Valley Clinic, in Bluefield, will be held at the Bloomfield Country Club, November 12th. Dr. Frederick D. White will discuss "Early Ambulation Following Cataract Surgery"; Dr. Oscar M. Weaver Jr., "*Bile Stasis*"; Dr. *William* F. Hillier Jr., Asheville, N. C., "Little Strokes"; Dr. John Borden Graham of the University of North Carolina School of Medicine, Chapel Hill, "Diagnosis and Treatment of Bleeding Disorders"; and Dr. Harry H. Ware Jr., of the Medical College of Virginia, Richmond, "Ectopic Pregnancy". There will be a social hour followed by a banquet at 7:00 p. m. at which Dr. Elbyrne G. Gill, Roanoke, Va., director of the Eye Bank and Sight Conservation Society of Virginia, will speak on "The Eye Bank's Contribution to Ophthalmology".

WISCONSIN

New Chairman of Department of Neurology.–Dr. Francis Michael Forster, formerly dean of the Georgetown University School of Medicine, Washington, D. C., has been named chairman of the department of neurology, University of Wisconsin Medical School, Madison. Dr. Forster has held medical school appointments at Harvard, Yale, Boston University, Jefferson, and Georgetown University. He has served as consultant to Veterans Administration and Armed Forces hospitals and to the Institute of Mental Health and is joint representative of the American Neurological Association and the American Academy of Neurology to the National Research Council.

GENERAL

Postgraduate Cruise to the Caribbean.–The University of Texas Postgraduate School of Medicine, Houston, announces its second Medical Cruise to the Caribbean. Lecturers have been obtained representing medicine, radiology, surgery, obstetrics and gynecology, and pediatrics. The group will sail from New Orleans May 5 on the M. S. Stella Polaris and return May 18. Twenty-five hours of scheduled teaching will be offered. Inquiries should be directed to The University of Texas, Postgraduate School of Medicine, Houston 25, Texas.

Public Health Physicians Meeting.–The American Association of Public Health Physicians will meet at Kiel Auditorium in St. Louis October 29. Dr. Sanford P. Lehman of Seattle, Washington will give the presidential address. Dr. Carl J. Potthoff of the University of Nebraska College of Medicine, Omaha, will discuss "Television Advertising of Health Related Products". The panel discussion will be moderated by Dr. Bruce Underwood of Washington, D. C. and the other speakers will be Drs. Wilson T. Sowder of Jacksonville, Florida; Harold M. Erickson of Portland, Oregon; Benjamin Freedman, New Orleans, and Roger F. Sondag of Murphysboro, Illinois.

Report on Accident Mortality.–Accidents in public places are a major source of mortality in our country, statisticians of the Metropolitan Life Insurance Company report. Each year more than 55,000 persons are killed in accidents on streets, highways and in other public places. Three times as many males as females are victims. The bulk of motor vehicle fatalities are among drivers and passengers in cars that collide with other vehicles, railroad trains, or fixed objects, or in cars which overturn. Only about one-fifth of the *deaths are* among pedestrians. Accidental falls in public places take about 5,000 lives, nearly half being fatally injured in homes for the aged, hospitals, and in other resident institutions.

Postgraduate Assembly in Boston.–The 16th annual New England Postgraduate Assembly, a three-day program, will be held at the Statler-Hilton, Boston, Nov. 4-6, under the auspices of the six New England state medical societies and chapters of the American Academy of General Practice. Dr. Kenneth W. Warren, representing the Massachusetts

Medical Society, is chairman. In addition to morning clinics at Boston hospitals, the program will include lecturers, panel discussions, clinicopathological conferences, luncheon symposiums, medical films, and scientific and technical exhibits. A special program for wives of attending physicians has been arranged. For information write the New England Postgraduate Assembly, 22 The Fenway, Boston 15.

Student Awards for Research.—Sheard-Sanford prizes for meritorious research by medical students have been awarded to 13 students specializing in pathology, Dr. Joseph E. Flynn, of Columbia, Mo., chairman of the Research Committee of the American Society of Clinical Pathologists, has announced. The awards of $100 each are financed by royalties from the photelometer designed by Drs. Charles Sheard and Arthur H. Sanford of the Mayo Clinic, Rochester, Minn. The Sheard-Sanford Fund was first used to provide cash prizes for praiseworthy research performed by young members of the pathology society. The policy was changed in 1954 to one of providing prizes for medical students conducting meritorious research and there was one student winner that year. In 1955 there were 6. This year's 13 awards are the first given since then.

Awards for Neurological Research.—The National Neurological Research Foundation has announced that three National Neurological Research Foundation scientists will receive awards of from $10,000 to $12,000 a year for five years. These awards will unite basic research on multiple sclerosis, Parkinson's syndrome, amyotrophic lateral sclerosis, muscular dystrophy, cerebral palsy, epilepsy, and other clinical entities. The foundation is a nonendowed voluntary tax-exempt organization with headquarters at 3255 N Street, N. W., Washington, D. C. The foundation scientists are: Dr. Michael V. L. Bennett, D.Phil., research associate, department of neurology, College of Physicians and Surgeons, Columbia University, New York City; Dr. Byron H. Waksman, assistant professor, bacteriology and immunology, Harvard Medical School, Boston; and Dixon M. Woodbury, Ph.D., associate research professor of pharmacology, University of Utah College of Medicine, Salt Lake City.

Meeting of Society for Crippled Children.—The National Society for Crippled Children and Adults will meet Nov. 16-20 at the Statler Hotel, Dallas, Texas. The speakers will include specialists in rehabilitation, medicine, welfare, business, industry, and government. Four society counselors will be cited for their "outstanding contributions" in the field of cerebral palsy at the annual meeting: Drs. George G. Deaver, professor of physical medicine, New York's Bellevue hospital; Leslie B. Hohman, professor of psychiatry, Duke University Medical School, Durham, N. C.; Winthrop M. Phelps, medical director, Children's Rehabilitation Institute, Reisterstown, Md.; and Meyer A. Perlstein, chief, Children's Neurological Service, Cook County Hospital, Chicago. There will include institutes, seminars, workshops, round-table discussions, and demonstrations in rehabilitation. The social program includes a shrimp boil sponsored by the Louisiana Chapter of the society, a chuck wagon dinner, the annual president's banquet, square dances, and tours. For information write The National Society for Crippled Children and Adults, 11 S. LaSalle St., Chicago 3.

Southern Medical Association Meeting.—The annual meeting of the Southern Medical Association will be held in New Orleans November 3-6. In addition to a four-day schedule of scientific work presented by physicians from various cities throughout the United States, other societies which will meet will be the Southern Chapter of the American College of Chest Physicians; the Southern Section of the Association for Research in Ophthalmology; the Southern Gynecological and Obstetrical Society, and the Flying Physicians Association. More than 30 alumni groups of southern medical colleges will meet and an elected representative of the senior classes of southern medical schools will be guests of the association. Dr. Francis J. L. Blasingame, Chicago, executive vice president of the American Medical Association, will speak at the president's luncheon on Monday, November 3. According to the bulletin of the Southern Medical Association, plans have been made for the adjourned sessions of the Southern Medical Association's 52nd annual meeting in Mexico. Information concerning these sessions may be obtained from Southern Medical Association headquarters, 2601 Highland Ave., Birmingham 5, Ala.

Poliomyelitis.—According to the Morbidity and Mortality Weekly Report of the United States Public Health Service, dated September 26, 1958, the total number of cases of poliomyelitis reported for the week ended September 20 is 434; 220 of these were paralytic cases and 141 were nonparalytic. The total number of reported cases this week is about 10 percent higher than the previous week's figure, and the number of paralytic cases is about 15 percent higher. The total number of reported cases for the week ended September 21, 1957, was 212, of which 82 were paralytic and 93 nonparalytic. The cumulative total of paralytic cases is now above the cumulative figure for the same period last year. About half of the total cases and about 40 percent of the paralytic cases were reported in the East North Central area, where Michigan continues to report a high number of cases—129 total with 58 paralytic cases. The number of cases reported in Ohio is continuing to increase; 46 cases were reported this week compared with 38 last week. The number of paralytic cases has decreased slightly, however. The cases in Ohio have been distributed over most of the State. The peak week of paralytic cases since 1954 has occurred once each in the third and fourth weeks of September.

Association of Military Surgeons meeting in Washington.—The 65th annual convention of the Association of Military Surgeons of the United States will be in the Statler-Hilton Hotel, Washington, D. C., November 17-19 under the presidency of Col. Charles R. Mueller, M.D., U. S. Army, retired. The theme of the meeting will be "Dynamic Medicine and Rehabilitation in the Space Age". General Alfred M. Gruenther, president, American National Red Cross, will speak at the opening ceremonies, followed by a panel of service chiefs at which Major General George F. Lull, U. S. Army, retired, assistant to the president of the American Medical Association, will be the moderator. Monday afternoon there will be a panel meeting on "Problems of Space", the moderator being Brigadier General Don Flickinger of the Andrews Air Force Base, Washington, D. C. There will be a symposium on "Rehabilitation" presided over by Dr. Charles D. Shields, director, Department of Physical Medicine and Rehabilitation, Georgetown University Medical Center, Washington, D. C., and a panel on "Occupational Health Problems in Space Flight", moderated by Major General Wilford F. Hall of the Wright-Patterson Air Force Base, Ohio. There will be meetings of various sections—pharmacy, nurse corps, dental corps, medical specialist corps, and sustaining membership. At the honors night dinner and dance, the various awards of the Association will be presented.

National Foundation for Research in Cutaneous Medicine.—Formation of The National Foundation for Research in Cutaneous Medicine to support and promote research in the field of skin diseases has been announced by the president of the foundation's board of trustees, Louis L. Spirt. The objectives of the foundation are "to promote the advance of medical science in the field of cutaneous diseases, afflictions and ailments", and "to stimulate, support and coordinate research, experiments, tests and studies on a broad scale". Another objective is to carry on an intensive educational campaign aimed at the general public on the subject of skin diseases by way of specially prepared articles and pamphlets and eventually by the use of special radio and television programs. The announcement says that a spokesman for the foundation estimated that a total of 25 million people in the United States are afflicted with some form of skin disease requiring medical attention and that some 4 million people suffer from psoriasis alone.

Members of the still incomplete medical advisory board of the foundation include Drs. Marion B. Sulzberger, New York City; Jasper Lamar Callaway, Durham, N. C.; Frank C. Combes, New York City; Stephen Rothman, Chicago; Herbert Mescon, Boston; Jonas F. Mullins, Galveston, Texas; Harvey Blank, Miami, Florida; Earl D. Osborne, Buffalo, New York; William L. Dobes, Atlanta, Georgia; Milton Reisch, New York City; Arthur C. Curtis, Ann Arbor, Michigan, and Lawrence G. Beinhauer, Pittsburgh, Pa. The address of the foundation is 370 Lexington Avenue, New York, 17, N. Y.

International Symposium on Tuberculosis.—A three-day International Symposium will be held in Philadelphia under the auspices of Deborah Sanatorium and Hospital. Panelists will hold scientific discussions at the Bellevue-Stratford Hotel, Nov. 20-22, ending with a medical tour of the Sanatorium at Browns Mills, N. J., Nov. 23. The chairman of the Symposium Planning Committee is Dr. George N. J. Sommer Jr., of Trenton, N. J. Participating in the symposium from abroad will be Drs. Georges Canetti, of Paris; Johannes Holm, of Geneva; Frederick R. Edwards, of Liverpool; John R. Bignall, John M. Robson, and Philip M. D. Hart, of London; Carl B. Semb and Hans J. N. Ustvedt, of Oslo. The following panel discussions (and chairman) are planned:

Chemotherapeutic Prophylactic Measures for Tuberculosis, Dr. Walsh McDermott, New York City.
The Hospital and Home, Respective Roles in Tuberculosis Management; Chemotherapy of Tuberculosis, Dr. William B. Tucker, Washington, D. C.
Problem of Relapse of Tuberculous Lesions Under Chemotherapy and Following Treatment; Dr. Gardner Middlebrook, Denver.
Tuberculosis Case-Finding; The Problem in the General Population, Schools and Hospitals, Dr. Katharine R. Boucot, Philadelphia.
Surgical Aspects of the Treatment of Pulmonary Tuberculosis; Type of Operation, Relationship to Chemotherapy, to Bacteriological Status, to Pathology of Treated Tuberculosis, Dr. John M. Chamberlain, New York City.
The Future Problem of Tuberculosis; Program for Its Control, Dr. David A. Cooper, Philadelphia.

For information write Mr. Robert J. Bramlett, 642 Widener Building, Philadelphia 7.

Meeting of Gerontological Society.—The 11th annual meeting of the Gerontological Society will be at the Bellevue-Stratford Hotel, Philadelphia, November 6-8. The chairmen of the introductory session will be Dr. Warren Andrew, professor of anatomy, Bowman Gray School of Medicine of Wake-Forest College, Winston-Salem, N. C., and Joseph T. Freeman, assistant professor of medicine, Women's Medical College of Pennsylvania, Philadelphia. Other speakers at this session will be Nathan W. Shock, Ph.D., of the U. S. Public Health Service, Bethesda, Maryland; Gunnar Gundersen, LaCrosse, Wisconsin, President, of the American

Medical Association; Robert J. Havighurst, Ph.D., professor of education, University of Chicago, and Ollie A. Randall, consultant on aging, Community Service Society, New York City. There will be sessions also on "Clinical Medicine", "Biological Sciences", "Psychological and Social Sciences", "Social Welfare", and a public meeting at 8:00 P. M. Thursday on "Gerontology and the National Scene". On Friday there will be a symposium on "Gerontology in Biology and Medicine" and one on "Gerontology in Social and Psychological Sciences and Social Welfare". Friday evening there will be a reception and social hour, followed by a banquet, the award sponsored by the Gerontological Research Foundation, and the presidential address by Albert I. Lansing, Ph.D., professor of anatomy, University of Pittsburgh School of Medicine. On Saturday there will be concurrent sessions on "Biological Sciences", "Clinical Medicine", "Psychological and Social Sciences", and "Social Welfare".

Meeting of Society for Hypnosis.—The 10th annual meeting of the Society for Clinical and Experimental Hypnosis will be at the Morrison Hotel, Chicago, October 29-31. This meeting will also mark the first annual meeting of the International Society for Clinical and Experimental Hypnosis.

The program will include breakfast seminars, round table luncheons, panel discussions and formal presentations. Preceding the annual meeting the Institute for Research in Hypnosis of the Long Island University Graduate School will present its annual workshop in clinical hypnosis, October 27-29 at the Morrison Hotel.

Among the subjects for panel discussions will be: "Hypnosis in Internal Medicine"; "Hypnoanesthesia in Obstetrics"; "Hypnotherapy in Gynecology"; and "Implications of Hypnotherapy for Psychosomatic Medicine". Among the subjects for round table luncheons and seminars will be: "Group Hypnotherapy in Obesity"; "Use and Abuse of Hypnosis in General Practice"; "Hypnosis in Asthma and Allergic Manifestations"; "Hypnoanesthesia for Minor Surgical Procedures"; "Hypnotherapeutic Management of the Schizophrenic Patient"; "Use of Hypnosis in Chronic and Acute Pain," and "Hypnosis in Management of Traumatic Injuries."

The meeting is open to physicians, dentists and psychologists, the registration for non-members being $10.00 and $5.00 for residents and interns.

The president of the Society for Clinical and Experimental Hypnosis is Dr. Bernard Boris Raginsky of Westmount, Quebec, Canada, and the chairman of the program committee is Dr. William S. Kroger of the Chicago Medical School.

Meeting of Pathologists in Chicago.—The annual joint meeting of the American Society of Clinical Pathologists and the College of American Pathologists will be at the Congress Hotel, Chicago, November 1-8. The Executive Committee of the American Society will meet Friday evening, October 31 and all day and evening Saturday and Sunday. The clinical chemistry workshop on "Liver Function Tests" will begin at 8:30 A. M., Saturday, at the University of Illinois Medical School and continue all day and all day Sunday. The forensic pathology workshop on "Homicide Investigation" will continue all day Sunday at the Chicago Police Department laboratory. Sunday evening there will be a joint reception and dinner for the councillors of the American Society and the assemblymen of the college. The panel discussions begin Monday morning on "Radioisotopes in Routine Laboratory Tests", "Anesthetic Deaths", "Role of Blue Shield and Other Third Parties in Payment for Pathology Services", and "Relation of Pathologists to Paramedical Groups". The presidential address by Dr. Charles P. Larson, Tacoma, Washington, will begin at 11:40 A. M., Monday. The hematology workshop continues through Monday morning, while the microbiology workshop goes on throughout the day. On Thursday morning there will be a joint symposium of the two societies on "Role of the Laboratory in the Diagnosis and Management of Diseases of the Endocrine Glands". Tuesday afternoon there will be workshops on "Medical Writing", "Laboratory Administration", "Histochemistry", and "Interpretation of Laboratory Findings". The joint reception and banquet will be Tuesday evening. The presidential banquet of the College of American Pathologists will be on Wednesday and the Armed Forces Institute of Pathology luncheon on Thursday.

Southwestern Medical Association Meeting.—The annual meeting of the Southwestern Medical Association will be held at Tucson, Arizona, October 23-25, with headquarters at the Pioneer Hotel, under the presidency of Dr. Louis G. Jekel of Phoenix. The scientific sessions will be confined to morning and noon meetings, leaving the afternoons for sightseeing and sports. The program will include small round-table groups for doctors. Among the speakers will be:

Dr. George C. Andrews of Columbia University College of Physicians and Surgeons of New York City on "Diagnosis and treatment of common dermatoses of the hands"; Dr. John R. Schenken of the University of Nebraska, College of Medicine, on "The Cystic Ovary—Surgical or Non-Surgical"; Dr. John I. Brewer of Northwestern University Medical School, Chicago, on "Pelvic Pain"; and Dr. Robert M. Zollinger, Ohio State University, College of Medicine, Columbus, on "The Surgical Importance of Pancreatitis". There will be a seminar on pediatrics. The opthalmologists will have a meeting Friday morning and on Friday afternoon there will be medical movies and golf, and in the evening a cocktail party and dinner. The Saturday morning session will include "Basic Issues in American Education" by Richard A. Harvill, Ph.D., president of the University of Arizona, Tucson, "Thyroid Physiology and Brain Function—Alocholism and Hangovers" by Dr. Henry J. Koch. "Subdural Hematomas in the Elderly" by Dr. Peter H. L. Stuteville of the University of Colorado Medical Center, Denver, "Recognition and Treatment of Respiratory Acidosis" by Dr. Reginald H. Smart, Los Angeles, "The Cataract Patient in General Practice" by Dr. John W. Henderson, Rochester, Minn., and "Pulmonary Tuberculosis in Childhood" by Dr. Robert H. Lennox, New Orleans.

The Southwestern Dermatological Society will also have a specialty group meeting and on Saturday afternoon there will be golf and in the evening a football game between the University of Arizona and the University of Idaho.

CORRECTION

Studies with Chlorothiazide: An Oral Diuretic.— The dose of chlorothiazide in the fourth line of the second column of the abstract on this subject in THE JOURNAL, Sept. 27, 1958, issue, page 468, should have been 1 Gm. and not 10 Gm. twice daily.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral Examination.* Phoenix, April 5-10, 1959. The 1959 written examination will be given in various locations in the United States and Canada, July 17. The final date for filing application for the 1959 written examination is six months prior to the examination. There is no filing deadline for oral examinations. Sec., Dr. Curtiss B. Hickcox, 217 Farmington Ave., Hartford 8, Conn.

AMERICAN BOARD OF DERMATOLOGY: *Written. Several Cities,* June 30. Final date for filing all applications is April 1. Sec., Dr. Beatrice Maher Kesten, One Haven Ave., New York 32.

AMERICAN BOARD OF INTERNAL MEDICINE: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates in the South and Southwest, New Orleans, Feb. 3-6. Final date for filing application is Jan. 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application is Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application is March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application is March 1. *Examination in the Subspecialties. Gastroenterology.* Philadelphia, April 17-18. Final date for filing application is Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part I.* Various parts of the United States and Canada, January 16. Candidates notified of their eligibility to participate in Part I must submit their case abstracts within thirty days of notification of eligibility. No candidate may take the written examination unless the case abstracts have been received in the office of the Secretary. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

AMERICAN BOARD OF OPHTHALMOLOGY: *Written,* qualifying test (Part I), January 1959. Final date for filing application was July 1, 1958. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Part II.* Chicago, Jan. 21-23, 1959. Deadline for receipt of applications was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

AMERICAN BOARD OF PATHOLOGY: Chicago, Oct. 30-Nov. 1. Final date for filing application was Sept. 30. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

AMERICAN BOARD OF PEDIATRICS: *Oral.* New York, Dec. 5-7. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

AMERICAN BOARD OF PHYSICAL MEDICINE AND REHABILITATION: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application is February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York City, Dec. 15-16; New Orleans, Mar. 16-17. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 will be terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Regular Examination.* Washington, D. C., Dec. 8-11. Final date for filing application was July 1. *Special examination in Nuclear Medicine for those diplomates in Radiology or Therapeutic Radiology.* Washington, D. C., Dec. 6. Final date for filing application was Oct. 1. *Special Examination.* Cincinnati, Mar. 16-19, 1959. Final date for filing application is Nov. 1. Candidates completing training June 30, 1959 are not eligible for the Spring 1959 examinations. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

AMERICAN BOARD OF SURGERY: Written examinations (Part I) will be held at various centers in the United States, Canada, Hawaii, Puerto Rico, and certain military centers abroad on December 3. The date of the Fall examination in *Part I* has been changed from the last Wednesday of October as announced in its current Booklet of Information to December 3, 1958. Thereafter, examinations in Part I will be held once annually, on the first Wednesday of December. The closing date for filing applications was August 1. *Part II.* Rochester, Minn., Oct. 20-21; Nashville, Tenn., Nov. 17-18; New York City, Dec. 15-16; Houston, Tex., Jan. 12-13; New Haven, Conn., Feb. 9-10; Durham, No. Car., March 9-10; San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

BOARD OF THORACIC SURGERY: Various centers throughout the United States. *Written.* Spring of 1959. Final date for filing application is December 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Avenue, Detroit 2.

AMERICAN BOARD OF UROLOGY: *Written Examination.* Twenty-five cities throughout the country, Dec. 5. The oral will be given in Chicago in February 1959. Sec., Dr. William Niles Wishard, Jr., 30 Westwood Road, Minneapolis 26.

DEATHS

Blakley, Julius Warren, Highland, N. Y.; Albany (N. Y.) Medical College, 1896; died Aug. 14, aged 84.

Burch, Lewis J. Ⓜ Mount Pleasant, Mich.; Detroit College of Medicine, 1896; associated with the Central Michigan Community Hospital; died in the Sammond Pleasant Lodge, Romeo, Aug. 17, aged 84, of cerebral thrombosis.

Clarenbach, Julius F. Ⓜ Sundance, Wyo.; Barnes Medical College, St. Louis, 1902; also a dentist; county health officer; died in St. Mary's Hospital, Rochester, Minn., Aug. 15, aged 80, of hydronephrosis.

Claybon, Festus, Madisonville, Ky.; Meharry Medical College, Nashville, Tenn., 1917; died in the Brooks Memorial Hospital, Hopkinsville, Aug. 9, aged 73.

Corse, Charles A., Kelliher, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; died June 23, aged 82, of coronary occlusion.

Daine, Donn David Ⓜ San Francisco; State University of Iowa College of Medicine, Iowa City, 1956; service member of the American Medical Association; interned at the Letterman Army Hospital; captain, medical corps, U. S. Army Reserve; found dead Aug. 11, aged 29, of an overdose of barbiturates, self-administered.

Dello Russo, Michael Ⓜ Medford, Mass.; Tufts College Medical School, Boston, 1946; certified by the National Board of Medical Examiners; veteran of World War II; fellow of the American College of Obstetrics and Gynecology; member of the New England Obstetrical and Gynecological Society; served on the staffs of the Malden (Mass.) Hospital, Lawrence Memorial Hospital in Medford, and the Boston City Hospital; died in St. Elizabeth's Hospital, Boston, Aug. 10, aged 36, of thrombocytopenic purpura.

Drouin, Wilfred George, Scranton, Pa.; School of Medicine and Surgery, Montreal, Que., Canada, 1903; an associate member of the American Medical Association; formerly practiced in Holyoke, Mass., where he was a member of the school board; veteran of World War I; died Aug. 27, aged 77.

Flesher, George Taylor Ⓜ Kermit, W. Va.; Medical College of Virginia, Richmond, 1934; specialist certified by the American Board of Otolaryngology; member of the American Otorhinologic Society of Plastic Surgery; died Aug. 14, aged 51, of a heart attack.

Green, David Samuel, Boston; Tufts College Medical School, Boston, 1922; veteran of World War I; member of the Massachusetts Medical Society; served on the staffs of the Boston City and Beth Israel hospitals; died Aug. 21, aged 60, of acute myocardial infarction.

Gridley, Norman Grandison Ⓜ Horseheads, N. Y.; University of Buffalo School of Medicine, 1929; veteran of World War II; school doctor for the Horseheads Central School District; for many years health officer; died Aug. 12, aged 56.

Griffith, Eugene Frederick, Eatonton, Ga.; University of Georgia Medical Department, Augusta, 1911; veteran of World War I; served two terms in the State Senate and two terms in the House of Representatives; served as a member of the city council and as mayor pro-tem; died Aug. 5, aged 69

Henry, Clyde A. Ⓜ Farson, Iowa; Keokuk (Ia.) Medical College, 1897; member of the American Academy of General Practice; associated with Ottumwa and St. Joseph hospitals; in 1952 named "Physician of the Year" by the Iowa State Medical Society; died Aug. 15, aged 85.

Hicklin, Frank E., Miami, Fla.; Washington University School of Medicine, St. Louis, 1897; died June 24, aged 85.

Hockenbery, Merritt L., Windgap, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1910, an associate member of the American Medical Association; died in St. Luke's Hospital, Bethlehem, Aug. 20, aged 72.

Houze, Harry George Ⓜ Westport, Conn.; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1924; member of the American Psychiatric Association; assistant superintendent of the Westport Sanitarium; died Aug. 22, aged 56.

Howard, Robert Warner, Washington, D. C.; Medico-Chirurgical College of Philadelphia, 1905; died Aug. 17, aged 83, of cardiovascular disease.

Humphrey, Wade Randall Ⓜ Stillwater, Minn.; University of Maryland School of Medicine, Baltimore, 1902; fellow the American College of Surgeons; member of the American Association of Railway Surgeons; veteran of World War I; died in the Lakeview Memorial Hospital Aug. 23, aged 79, of arteriosclerotic heart disease.

Ⓜ Indicates Member of the American Medical Association.

Hurrell, M. Louise, Saugerties, N. Y.; University of Buffalo School of Medicine, 1902; an associate member of the American Medical Association; during World War I served in France as the head of the American Women's Hospital, Unit I, under the sanction of the French government; for her service was awarded the Croix de Guerre with Palm and the Medal of Epidemics with Palm, and was made an honorary citizen of France by the government; died in De Bary, Fla., Aug. 8, aged 87, of cancer of the rectum with metastasis.

Jarrell, Columbus Marion, Epps, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; past-president of the East and West Feliciana Bi-Parish Medical Association; formerly on the staff of the Baptist Hospital in Alexandria; died Aug. 11, aged 86, of coronary occlusion.

Judd, Clarence Wrigley, Philadelphia; University of Maryland School of Medicine, Baltimore, 1913; an associate member of the American Medical Association; died Aug. 19, aged 70, of cerebral hemorrhage.

Kelly, William Francis, Gulfport, Fla.; Medico-Chirurgical College of Philadelphia, 1907; an associate member of the American Medical Association; member of the Medical Society of the State of Pennsylvania; died Aug. 2, aged 78.

Le Golvan, Celestin Ⓜ Marquette, Mich.; Université de Paris Faculté de Médecine, France, 1911; for many years county jail physician; on the staffs of St. Mary's and St. Luke's hospitals; died in Montreal, Que., Aug. 14, aged 73, of endocarditis, hypertension and diabetes mellitus.

Levy, Harry Robert Ⓜ Dallas, Texas; Southwestern University Medical Department, Dallas, 1910; veteran of World War I; on the staff of St. Paul Hospital and the Baylor University Hospital, where he died Aug. 21, aged 72, of cerebral thrombosis.

Lewis, Robert Ⓜ Denver; Louisville (Ky.) and Hospital Medical College, 1908; died Aug. 16, aged 74, of coronary thrombosis.

Lilly, Edward Ⓜ Shirley, Mass.; Tufts College Medical School, Boston, 1925; for many years medical examiner for the 10th Middlesex District; veteran of World War I; attending physician at the Shirley Industrial School for Boys; associated with the Ayer (Mass.) Community Memorial Hospital and Clinton (Mass.) Hospital; died Aug. 17, aged 58, of cancer of the larynx.

McAuliffe, William Joseph Jr., Snyder, N. Y.; Long Island College of Medicine, Brooklyn, 1934; veteran of World War II; died May 3, aged 49, of coronary heart disease.

McCoy, Earl Marcus Ⓜ Grand Ledge, Mich.; Detroit College of Medicine, 1902; veteran of World War I; served as health officer of Grand Ledge; at one time medical superintendent of the Michigan State Sanatorium for Tuberculosis in Howell; associated with the St. Lawrence Hospital in Lansing; died Aug. 21, aged 76, of arteriosclerotic heart disease.

McMillan, John Ezra, Fitzgerald, Ga.; Atlanta School of Medicine, 1912; on the staff of the Ben Hill County Hospital; died Aug. 4, aged 72, of coronary thrombosis.

Moran, William Grayson Ⓜ Cranberry, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1920; died Aug. 3, aged 62, of myocardial infarction.

Moser, William Calvert, St. Petersburg, Fla.; George Washington University School of Medicine, Washington, D. C., 1907; an associate member of the American Medical Association; formerly practiced in Morgantown, W. Va.; member of the West Virginia State Medical Association; past-president of the Monongalia County (W. Va.) Medical Society; died in the Hospital Division of the Veterans Administration Center, Bay Pines, Aug. 8, aged 76, of nephritis.

Moulton, John Henry Ⓜ Rangeley, Maine; Medical School of Maine, Portland, 1914; died July 31, aged 68, of myocardial infarction.

Murray, John Watts Ⓜ Warsaw, Mo.; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1910; died in the Bothwell Hospital, Sedalia, Aug. 11, aged 78, of pulmonary embolism and arteriosclerotic heart disease.

New, James Legrand, Lake Mahopac, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York City, 1892; an associate member of the American Medical Association; died July 22, aged 87.

Nimer, Melvin Arthur Ⓜ assistant surgeon, U. S. Public Health Service Reserve, Staten Island, N. Y.; University of Utah College of Medicine, Salt Lake City, 1956; interned at the U. S. Public Health Service Hospital in Seattle; service member of the American Medical Association; resident at the U. S. Public Health Service Hospital, Stapleton; stabbed to death Sept. 2, aged 31.

O'Brien, Daniel Patrick, Torrington, Conn.; born in Torrington Feb. 25, 1894; Johns Hopkins University School of Medicine, Baltimore, 1920; served as medical officer on Admiral Richard E. Byrd's expedition to the North Pole in 1926; in 1927 joined the Rockefeller Institute for Medical Research in New York City and retired in 1947 as administrator of the medical science and research division; from his headquarters in Paris traveled for the foundation to scientific and research centers throughout Europe; received a British medal for services to medical education and the promotion of international relations between medical men; died in Acapulco, Mexico, Aug. 16, aged 64, of diabetes mellitus.

Quimby, Adoniram Judson, New York City; Ohio Medical University, Columbus, 1905; also a graduate in pharmacy; an associate member of the American Medical Association; member of the American Roentgen Ray Society; specialist certified by the American Board of Radiology; associated with the New York Polyclinic Medical School and Hospital; died in St. Barnabas Hospital Aug. 24, aged 83.

Ray, John B., Leaksville, N. C.; Baltimore Medical College, 1898; member of the Medical Society of the State of North Carolina; served as mayor of Leaksville and for many years a member of the school board; served as chairman of local Selective Service Board during World Wars I and II; chairman of the county public health board; president of the Home Savings and Loan Association; vice-president of the Leaksville Bank & Trust Company; died in the Tri-City Hospital Aug. 13, aged 82.

Rehbock, Donald Jacob Ⓜ Los Angeles; University of Pennsylvania School of Medicine, Philadelphia, 1930; formerly on the faculty of Western Reserve University School of Medicine, Cleveland; specialist certified by the American Board of Pathology; veteran of World War II; member of the American Association of Pathologists and Bacteriologists, and the American Society of Clinical Pathologists; founding fellow of the College of American Pathologists; on the staff of St. Francis Hospital in Lynwood, Calif.; died in the Good Samaritan Hospital Aug. 2, aged 54, of metastatic carcinoma of the prostate.

Richardson, Lawrence Lafayette Ⓜ Simpsonville, S. C.; Atlanta Medical College, 1894; for many years mayor; past-president of the Greenville County Medical Society; for 20 years chairman of the board of trustees of the public schools; died Aug. 9, aged 91.

Saulpaugh, Lincoln Moses, Vero Beach, Fla.; Columbia University College of Physicians and Surgeons, New York City, 1920; an associate member of the American Medical Association; formerly practiced in New York City, where he was for many years associated with the Morrisania City Hospital; fellow of the American College of Surgeons; died in the Indian River Memorial Hospital Aug. 8, aged 63, of cerebral thrombosis.

Scully, Robert Emmet, Somerville, N. J.; University of Virginia Department of Medicine, Charlottesville, 1918; served on the staff of the Veterans Administration Hospital in Lyons; veteran of World War I; died in Trenton (N. J.) State Hospital Aug. 6, aged 83.

Siegfried, Joseph Howard Ⓜ Lacon, Ill.; University of Illinois College of Medicine, Chicago, 1936; on the staff of the Methodist Hospital of Central Illinois; died in the Peter Bent Brigham Hospital, Boston, Aug. 11, aged 49.

Simmons, William Arthur, Tower Hill, Ill.; Barnes Medical College, St. Louis, 1905; veteran of World War I; served on the staff of the East Moline (Ill.) State Hospital; died in Kirkwood Aug. 7, aged 79, of valvular heart disease.

Stern, Adolph, New York City; Columbia University College of Physicians and Surgeons, New York City, 1903; served as vice-president of the American Psychoanalytic Association; member of the American Psychiatric Association; past-president of the New York Psychoanalytic Institute; an associate member of the American Medical Association; died in the Lenox Hill Hospital Aug. 22, aged 79.

Truslow, Walter, Brooklyn; Long Island College Hospital, Brooklyn, 1895; an associate member of the American Medical Association; fellow of the American College of Surgeons; served on the faculty of his alma mater; member of the American Orthopaedic Association; at one time associated with New York Hospital for the Ruptured and Crippled, Brooklyn Jewish Hospital and Kings County Hospital; author of "Body Poise"; died Aug. 20, aged 87, of cerebral thrombosis.

Van Del, Dwight Tedcastle Ⓜ Kansas City, Mo.; Rush Medical College, Chicago, 1926; specialist certified by the American Board of Obstetrics and Gynecology; past-president of the medical staff at Menorah Hospital and a staff member of Kansas City General Hospital, Queen of the World Hospital, and St. Joseph Hospital; died in the Menorah Hospital Aug. 12, aged 58, of cancer.

Ward, John Hardin, Louisville, Ky.; University of Louisville (Ky.) Medical Department, 1904; veteran of World War I; died Aug. 2, aged 76, of a gunshot wound in the left chest, self-inflicted.

Webber, Henry Allen Ⓜ Colonel, U. S. Army, retired, White Hall, Md.; Harvard Medical School, Boston, 1896; service member of the American Medical Association; fellow of the American College of Surgeons; entered the regular Army in 1897; became a colonel in 1917; retired Nov. 16, 1928; died in Baltimore May 9, aged 87, of congestive heart failure.

Zavisca, Joseph Albert Ⓜ Buffalo; University of Buffalo School of Medicine, 1932; certified by the National Board of Medical Examiners; on the staffs of the Millard Fillmore, Buffalo General, and Kenmore Mercy hospitals; died Aug. 14, aged 51.

FOREIGN LETTERS

BRAZIL

Gastric Sarcoma.—According to Dr. Haroldo Sodré and co-workers (*Revista de Medicina e Cirurgia de São Paulo,* vol. 18, no. 3, 1958) reticular sarcoma of the stomach is rare and the clinical findings are indefinite even with the aid of radiology, cytology, and gastroscopy. It can be diagnosed exactly only by the pathologist. The long confused pathological conception of reticular sarcoma has become clear in the last few years. In the case reported the symptoms were atypical; roentgenograms taken July 11 and Aug. 9, 1957, suggested, respectively, carcinoma of the antrum and absence of mucosa at the level of the gastric antrum. Two gastroscopic examinations and the gastric cytology did not arouse suspicion of the presence of a reticular sarcoma. The diagnosis was established after the pathological examination had been made, and a subtotal gastrectomy with wide resection of the tumor was performed. As of March, 1958, the patient was in good general health.

INDIA

Multiple Sclerosis.—Laha and Johri observed a series of 16 patients with multiple sclerosis between 1954 and 1956 (*Journal of the Association of Physicians of India,* vol. 6, July, 1958). The total number of neurological patients seen in this period was 494, thus giving an incidence of multiple sclerosis among neurological diseases of 3.2%. The age of the patients varied from 16 to 50 years, 10 being under 35. There was no evidence of a hereditary factor. A precipitating factor (possibly coincidental) was found in two—childbirth in one and an attack of typhoid in the other. The onset was insidious in 14 and sudden in 2. All gave a history of remissions. Spastic paraplegia was the commonest manifestation, being seen in 11. Only one had hemiplegia. Charcot's triad was found in four. Nystagmus was present in 11 patients, but the jelly nystagmus was seen on ophthalmoscopy in only one. Two patients showed Romberg's sign; two had euphoria; and one had fully established compensated mitral stenosis, but this association was incidental.

Hepatic Cirrhosis.—I. J. Pinto and co-workers treated patients who had advanced hepatic cirrhosis with packed erythrocyte transfusions. Although most patients with hepatic cirrhosis do well on a high-protein diet, a few develop symptoms of portal-systemic encephalopathy which disappear when the protein content of the diet is reduced, while if concentrated proteins are given intravenously, there is a likelihood of loading the circulation with fluid and electrolytes. Packed cells can be used as a concentrated protein low in sodium as they contain 25 to 30% of hemoglobin which consists of 4% hemin moiety and 96% globin moiety. Six patients who had hepatic cirrhosis with ascites were given such transfusions after preliminary investigations and a period of stabilization of 15 to 30 days in hospital. The patients were weighed daily, and hemoglobin and plasma protein estimations were made weekly. They were kept on the routine hospital diet supplying 2,418 calories and containing 80.5 Gm. of protein, 335.5 Gm. of carbohydrate, 74.2 Gm. of fat, and 1.46 Gm. of sodium.

For transfusion, either the type-specific cells were used after cross matching or packed erythrocytes of group O blood were used; 200 to 300 ml. of such packed cells diluted with 100 ml. of 5% dextrose solution were given intravenously not later than six hours after separation from the plasma. These transfusions were repeated at intervals of 7 to 14 days, each patient receiving 1,300 to 2,000 ml. of packed cells. The effect on the clinical condition, especially the mental state, ascites, and serum proteins was observed. A marked improvement was seen in all patients except one with disappearance of ascites and edema. Three patients also showed marked loss of weight. No mental symptoms developed during treatment. The hemoglobin level showed a gradual increase in patients who responded, but none developed polycythemia. The serum globulin showed a fall after an initial rise, while the serum albumin started rising later after the globulin had come down to normal. No reaction to transfusion was seen in any of the patients. The results were, on the whole, comparable to those obtained with a high-protein diet.

Antidiuretic Factor and Ascites.—Berry and Sur (*Journal of the Association of Physicians of India,* vol. 6, July, 1958) stated that many workers have shown the role of antidiuretic factors in the pathogenesis of edema. The authors studied the role of such factors in 22 patients with ascites and 3 normal subjects. Their investigations included the total urinary output, complete hemogram, urinalysis, estimation of serum proteins, liver function tests, and examination of the ascites fluid. Transplenic portal venography was done in some cases if portal hyper-

The items in these letters are contributed by regular correspondents in the various foreign countries.

tension was suspected and barium swallow fluoroscopy of the esophagus, esophagoscopy, and proctoscopy were performed to detect the presence of varices. Liver biopsy was performed in a few cases. The antidiuretic substances in the urine were studied by the method of Noble and others, using rats. The series included 13 patients with hepatic cirrhosis, 2 with subacute nephritis, 2 with cardiac cirrhosis, 2 with tuberculous peritonitis, 2 with kwashiorkor, and one with polyserositis and congestive cardiac failure. The presence of antidiuretic factors in the urine could be demonstrated in all subjects except the normal controls and those with tuberculous peritonitis. The serum protein level was below normal in most, but there was no correlation between the degree of hypoproteinemia and the delay in diuresis produced in rats. A fair degree of correlation was noted between the degree of oliguria and the degree of ascites, except in some patients with hepatic cirrhosis. Five of these who were investigated for the presence of portal hypertension gave positive results.

The causative factors in the production of ascites in hepatic cirrhosis are probably portal hypertension, diminished colloid osmotic pressure due to hypoproteinemia, and the action of antidiuretic factors. Portal hypertension by itself has been shown to be unable to produce ascites, but, acting with hypoproteinemia and antidiuretic factors, it leads to localized retention of fluid in the peritoneal cavity. The increased antidiuretic activity in hepatic disease may be due to the diminished inactivation of antidiuretic factor, which is believed to be the normal function of the liver. The presence of antidiuretic substances in cardiac cirrhosis could be also due to liver damage, but its presence in patients with subacute nephritis is difficult to explain and may be due to hypoproteinemia leading to liver damage. In patients with ascites due to inflammation, as in tuberculous peritonitis, there was no increase in antidiuretic activity, but this was seen in the patients with polyserositis in whom, although the ascites was of inflammatory origin, the superimposition of congestive cardiac failure could be responsible for the presence of antidiuretic factor in the urine.

Ferrous Succinate for Hypochromic Anemia.—Parekh and Rane (*Journal of the Association of Physicians of India,* vol. 6, July, 1958) treated 32 patients who had hypochromic anemia (16 medical and 16 antenatal) with ferrous succinate. Each tablet contained 150 mg. of ferrous succinate or 35 mg. of metallic iron. Patients with iron deficiency anemia whose hemoglobin was below 10.5 Gm. per 100 ml. were selected. The investigations included determination of hemoglobin photometrically, erythrocyte count, packed cell volume, icteric index, blood protein estimation, bone marrow examination, and, when necessary, stool examination and a roentgenogram of the chest. Each patient received one tablet three times a day, children receiving a smaller dose. The average initial hemoglobin content in this group was 8 Gm. per 100 ml. The efficacy of the drug was judged on the basis of the mean daily rise of hemoglobin. Most patients showed a satisfactory response both clinically and hematologically, the mean hemoglobin rise per day being 1.06%. The medical patients showed a higher daily rise than did the antenatal and children responded better than adults. Six patients showed a poor response, and, of these, two had tuberculosis and one had untreated ankylostomiasis. There were no side-effects in any of the patients. Even children tolerated the drug well, except for one who developed staining of the teeth. The daily rise in hemoglobin level was greater when the initial level was low. The rise was more rapid in the beginning and became slower after a certain level was reached.

Serum Proteins in Hepatic Cirrhosis.—Misra and Bajpai (*Journal of the Association of Physicians of India,* vol. 6, July, 1958) studied the electrophoretic pattern of serum proteins in 36 patients with hepatic cirrhosis. The total serum protein levels were lowered in all patients. The serum albumin level was lower than normal and the alpha globulin level was raised in 72% of the patients, the alpha 2 globulin level being raised more frequently than the alpha 1 globulin fraction. The beta globulin level was raised in only two patients who showed evidence of biliary obstruction in the form of jaundice and a raised serum alkaline phosphatase level. It was below 9% in two patients who were in the terminal stages of hepatic failure. The gamma globulin level was raised in most patients. All these changes were more marked in those with than in those without ascites. The ascitic fluid contained a higher percentage of albumin than did the serum. The lowering of the albumin level was due to deranged hepatic function, the liver being its normal organ of synthesis while various factors might be responsible for the rise in gamma globulin. Thus it might indicate antibody response and might partly be due to incomplete disposal of gamma globulin or greater production of this fraction by the spleen which was increased in size in most patients with hepatic cirrhosis.

NORWAY

Antitobacco Campaign.—In a series of articles in *Aftenposten,* on the campaign against the misuse of tobacco, Professor Roald Opsahl reviewed the medical evidence against smoking. As a result of a meeting held in Stockholm in 1956 the government forbade the sale of tobacco to minors; 0.1% of the state's revenue from tobacco was earmarked for research into the ill-effects of tobacco. The Swedish

National Association against tobacco has a Norwegian counterpart with the title "Away with Tobacco." With a membership of over 1,500 and a periodical entitled *Pure Air*, it held a meeting last summer and passed certain resolutions, one of which advocated the prohibition of advertisements of tobacco in cinemas, the press, and elsewhere. These resolutions were presented to the Norwegian government, and a sympathetic reply was made by the Health Directorate.

Endarterectomy for Peripheral Arterial Insufficiency.—At the Oslo City Hospital, the surgical treatment of peripheral arterial insufficiency has of late been the object of the cooperation of a surgeon, internist, and radiologist. The surgeon, Dr. Carl Semb, reported on a series of 43 men and 10 women who had such operations as endarterectomy for lesions often due to arteriosclerotic changes in the lower limbs (*Tidsskrift for den norske lægeforening*, Aug. 1, 1958). Growing experience has led to a widening of the indications for operation, so a presentation of the patients operated on in the past two or three years cannot be taken as a guide to the selection of patients in the future. In 43 patients the operations were on the superficial femoral and popliteal arteries and in 13 on the iliac artery and the lower part of the aorta. The list of postoperative complications was surprisingly small, with only one death directly after the operation (uremia after amputation of one leg for gangrene). The immediate results of endarterectomy are encouraging. Though the author could not predict the ultimate results, he believed he would be justified in continuing this method of treatment.

UNITED KINGDOM

Gray's Anatomy.—The centenary is being celebrated of the publication of the first edition of Gray's Anatomy. In a review in the *British Medical Journal* of the recently published 32nd edition, Zachary Cope said that textbooks, like human beings, seldom live for 100 years. When they do, as in the case of Gray's Anatomy, it is because the original author hit on something which was urgently needed and the successive editors kept well in view the original purpose and faithfully adhered to it. In the preface to the first edition Henry Gray clearly stated his purpose, which was "to furnish the student and practitioner with an accurate view of the anatomy of the human body, and more especially the application of the same to practical surgery." With that intent he made many dissections, and his friend Vandyke Carter sketched several hundred of them for insertion in the new book. The publishers' records were destroyed in the war, but it is thought that about a million copies have been sold. Henry Gray was elected a Fellow of the Royal Society when he was only 25. He died after the publication of the second edition in 1860, when he was 34.

Suspended Animation.—At the meeting in Glasgow of the British Association for the Advancement of Science, Dr. A. S. Parkes said that long-term preservation of living cells by freezing was possible. Rats, mice, and dogs could be revived after being cooled to the freezing point and after heart beat and respiration had been arrested for an hour or more. Rats so treated showed no impairment of memory or learning capacity. At 0 C (32 F) the artificially cooled mammal has every appearance of being dead and by all clinical criteria is dead; yet, under appropriate conditions, it can be revived. To the biologist death is the state from which resuscitation of the body as a whole is impossible by any currently known means, but as knowledge increases the means of resuscitation will extend, so that what constitutes death today will not necessarily constitute death tomorrow. Victims of cold and exposure might sometimes be prematurely regarded as dead. Whether resuscitation in such cases, if it could be effected, would be justifiable in view of the possibility of permanent damage, is debatable, but the work on experimental animals suggests that this hazard is not as great as once thought. It has been found that the golden hamster could be resuscitated undamaged after cooling to −5 C (23 F) or freezing to the extent of crystallizing 50% of its body water. The process of biochemical disintegration after arrest of heart beat and respiration is slowed down but not stopped by cooling to 0 C. For long-term preservation in the frozen state much lower temperatures will be necessary. The induction of suspended animation at −80 C (−112 F) will no doubt necessitate the pretreatment of the mammal with some such substance as glycerol at a concentration which, according to present knowledge, is highly toxic.

Aspiration of Food and Vomitus.—An editorial in the *British Medical Journal* of Aug. 30 discusses a report by A. M. N. Gardner in the *Quarterly Journal of Medicine* (vol. 27, p. 227, 1958). Gardner directed attention to cases of unexplained death and complications that may have been due to aspiration. This is most likely to occur in infants and patients coming out of anesthesia. For infants, the aspiration of a large quantity of milk may be immediately fatal, particularly if they are feeble. Even repeated small aspirations may give rise to a variety of complications depending on the nature of the material aspirated. In anesthetized patients aspiration of the contents of the stomach is still a major cause of death. A full stomach, so common in labor, with pharyngeal and esophageal sphincters paralyzed by relaxants and reflexes depressed with barbiturates, is particularly conducive to regurgitation and aspiration.

The evidence that aspiration had occurred before death, even though perhaps agonal, rather than after death, is usually taken to be the presence of gastric contents in the bronchi and lungs at autopsy. To test this belief, Gardner placed barium sulfate in the stomach immediately after death. Radiographs taken at autopsy 24 to 48 hours later showed barium in the lungs in 7 of 10 bodies. The validity of such a fundamental means of proof as autopsy has therefore been shaken, and for this evidence to be acceptable in the future, measures must have been taken immediately after death to prevent postmortem gravitation of gastric contents into the lungs. Gardner went on to investigate the frequency with which aspiration takes place in life. Barium was placed in the drinks of patients after abdominal operations. In 10% barium reached the lungs. That this was due to aspiration of food and not vomitus was shown by the rarity of the occurrence when the drinks were placed in the stomach by tube. The diagnosis that aspiration has occurred in these circumstances is just as difficult during life as it is after death. Staining of the sputum, coughing after drinking, pyrexia, tachycardia, and hypotension are all suspicious findings.

Aspiration is a hazard of illness rather than of health and is particularly likely to occur in the feeding of recumbent patients who are old, ill, and perhaps narcotized. Prevention lies in insisting on drinking being done in a sitting position only. If this is impossible the common hospital feeding-cup appears to need redesigning, or drinking through a straw might be substituted for it. Gardner points out that the shape of the spout of the standard hospital feeding-cup enables fluid to be poured into the mouth and down the trachea of a recumbent patient, and the hooded top, by concealing from him both the quantity and orientation of the fluid, insures that he is taken by surprise. In the surgical wards aspiration is probably responsible for some cases of postoperative chest disease, and in the medical wards it may emerge as an important factor in some common pulmonary diseases. Outside the hospital, aspiration may kill the feeble infant in its cot, the heavy feeder intoxicated with alcohol on his couch, and the epileptic in the street. Any case of otherwise unexplained death should be suspect and aspiration as a factor carefully excluded, but if the diagnosis of aspiration is to be made at autopsy Gardner's work should be borne in mind.

Juvenile Delinquency.—Recent racial clashes were seen as part of the cause of increase in juvenile delinquency by experts at the annual meeting of the British Association for the Advancement of Science. At the moment colored people are apparently being singled out. Dr. R. G. Andry, senior clinical psychologist, St. Thomas's Hospital, London, thought that fathers who would not play a positive role in the family were the villains of the piece. Maternal deprivation was not all-important in causing delinquency. Many and possibly most fathers look on the training of the children as the mother's responsibility. Dr. Andry advocated schools for fathers where they could learn to play a more positive role in the family. He found that fewer children, among both delinquents and others, were going to church.

Health of Executives.—An attack is to be launched on the stress and other health hazards to which business executives are increasingly exposed. The aim is to make life more tolerable for the men and women who direct industry and commerce. The work will be done by a new medical research unit set up by the Institute of Directors. Industrial medicine is now well established but most of it has dealt with the problems of the worker. Little serious thought has been given to the health problems of the overworked executive. The British plan, wholly scientific in conception, will start by attempting to demonstrate the facts statistically, to define the causes and effects of the hazards to which executives are susceptible, and to find ways to overcome them. The project will start with an examination of health records to decide the health experience of executives and the risks to which they are exposed. Due allowance will be made for the fact that every man over 50 is somewhat abnormal. He cannot be expected to be as fit and full of energy as the 20-year-old. Flying has increased the strain on businessmen in that sometimes elderly men are transported within hours from bitter cold weather in Britain to the heat of the tropics, with little time for bodily adjustment to the sharp climatic change and the loss of the relaxation of a sea voyage. The strains imposed by "hospitality" will also be examined. The burden of too many heavy meals and too much alcohol, as businessmen meet and maintain contact with clients, has been underlined by several physicians in recent years.

Doctor Is Fined.—Dr. M. G. Lucas, 58, who was stated by his counsel to have "lived in torment" and became a drug addict to relieve suffering and pain, was fined a total of $910, after admitting to 13 charges of giving prescriptions for meperidine and diverting the drug to his own use. Arrangements were made for his hospitalization. Dr. Lucas had been in practice for about 23 years. He had been unable to get an assistant in his practice. He had tried to retire but the Ministry of Health would not permit this until he was 60. As a medical practitioner he said he considered that in 10 to 15 years meperidine would no longer be considered a dangerous drug.

CORRESPONDENCE

"FLAT FILM"

To the Editor:—I enjoyed the argument against the term "flat film" of the abdomen presented by Arnold and Washko in the June 7, 1958, issue of The Journal, page 773. Of course, the term should be banned. It is stated that there is no corresponding term in German. There is one: *Leeraufnahme,* meaning a film made without the use of an introduced contrast medium (*leer,* meaning empty; *Aufnahme,* meaning a photographic picture). This word was widely used in the 1920's and 1930's in Breslau, where I had my training. I am certain that it occurs often in the radiologic literature of that period and I am sure it is still in wide use. I have not followed today's German roentgenologic literature closely, but I cannot imagine why it should have fallen into disuse. It is a good descriptive word that plainly says what it means to say. Commonly, it was used for the scout film taken before injection of excretory urographic mediums; if one wanted a similar exposure for other reasons and with a modified technique, one so ordered, e. g., *Leeraufnahme im Stehen,* meaning scout film with patient standing.

Texas.

BIRTH WEIGHTS

To the Editor:—An interesting editorial on "Optimal Birth Weights" appeared in The Journal (167:470 [May 24] 1958). The New York City Department of Health, in collaboration with the physicians of the city, is actively probing problems such as those mentioned in the editorial. The wholehearted cooperation of the physicians in New York City in supplying to the department of health detailed information about deliveries has made possible numerous studies of obstetric problems that could not otherwise have been undertaken. One of these studies relates to the question of optimal birth weight raised in the editorial. The department of health in New York City found that the best weight (i. e., that for which perinatal mortality was lowest) occurred at 3,000 Gm. for males and 2,880 Gm. for females (Baumgartner and others, *Pediatrics* 6:329-342 [Sept.] 1950). For whites the optimum birth weight was determined as 2,990 Gm. as compared with 2,830 for nonwhites.

The influence of a possible difference in mean gestation periods for whites and nonwhites was raised in the cited paper, too. The data for that study were based on 1939-1940 experience. Since then reporting of weight information has improved. Moreover, following the Baltimore pattern, we are now asking physicians to supply the LMP date rather than length of gestation in weeks. As a result, 23% of live births are now calculated to have occurred at 40 weeks of gestation; whereas under the former method when length of gestation in weeks were reported, 64% or more of the live births were indicated as occurring at this specific gestation interval. This fact also relates to the editorial remarks in The Journal.

We intend to repeat the study of 1939-1940 with data for a more recent period. The better information now available should improve the precision of the data and permit its extension to an investigation of the influence of a possible difference in mean gestation periods for the various ethnic groups in the city. It will be useful clinically, if we can demonstrate that such differences in mean gestation periods actually exist for the various ethnic groups.

New York 13.

ANOXIA AND HYPOXIA

To the Editor:—An informative editorial, "New Facts About the Heart," appeared in The Journal (167:1504 [July 19] 1958). The achievements of Burns, Robson, and Smith deserve the high level of such recognition, but I was etymologically disturbed by the repeated use of the word anoxia in the review of their work. To those interested in cardiopulmonary physiology the use of the word anoxia when hypoxia is meant has the same anachronistic connotations as the use of auricular fibrillation for atrial fibrillation. Anoxia and hypoxia are not synonymous and interchangeable; it is doubtful that a state of anoxia or complete absence of oxygen ever occurs in any tissue, alive or dead. Hypoxia is a reduction in the normal levels of oxygen saturation. This is not a play on words but a definitive change in concept concerning gas metabolism not only in space medicine but in cardiopulmonary function. Since editorial comment in The Journal is now accepted as a "summit opinion" throughout the entire medical and scientific world, the selection and choice of words carries a burden of responsibility above and beyond that of any other publication. This is not intended to be a criticism of editorial policy but merely an attempt to point out the authoritative implications inherent in every Journal statement.

BUSINESS PRACTICE

This is the third in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

LEGAL HURDLES AND PROFESSIONAL ASSISTANCE

A physician needs a legal green light in the form of necessary licenses before he can open his office door to his first patients. Because medicine concerns itself with life and health, each state makes sure its medical men are properly qualified by licensing all physicians.

Normally, licenses are obtained from a board of physicians appointed by a state's governor to sit as an examining body. Such boards are most familiar with medical education programs within the state. Consequently, oral questions and basic science tests given applicants correspond closely to medical school curriculums in that state.

A physician who wants to practice in a state other than the one in which he trained may have to take additional examinations or meet other requirements. Every state has its own rules and regulations; some even require a doctor to pass a written basic science examination prior to taking a licensure test. Some states have reciprocity agreements with other states and may grant a license on the basis of a satisfactory examination given in another part of the United States. The National Board of Medical Examiners, a voluntary unofficial examining agency, awards a certificate to any graduate of an approved medical school who passes a special three-part examination. This certificate can simplify the process of securing a license in another state, since it is recognized by all states except Arkansas, Florida, Georgia, Indiana, Louisiana, Michigan, North Carolina, and Texas.

Because licensure requirements are so different, it is best to find out as soon as possible how to secure a license to practice. The American Medical Association will supply information on licensure regulations and dates on which licensing examinations are given in various states.

Physicians also must obtain a federal narcotics license, and some states require a license to dispense hypnotic drugs regularly. Others require professional or occupational licenses as well (see table).

Contacting the Medical Society

An early call at the offices of the state medical society and the county medical society is a wise action for a physician who decides to practice in a given area. He will receive a great deal of valuable information and assistance on how to proceed with establishing and building his practice. To help new M.D.'s, some societies have worked out detailed checklists of "things to do in opening a practice," right down to the last detail regarding licenses, necessary county and state forms, and federal regulations.

He will also receive information about the general range of medical fees in the locality, so that he can build his own fee schedule, and he will find out the customary ways of announcing a practice. He can inquire about becoming a member of the local medical society—learn about hospital privileges and how to secure them. This information will save him time and trouble, help him get started on the right foot with his colleagues, and aid in establishing a pleasant relationship with other physicians which probably will continue for many years.

Membership in medical organizations at local, state, and national levels pays rich dividends, especially to the physician just starting out in practice. Regular society programs, special conventions, and scientific publications help him pursue his postgraduate education. Through his membership in these organizations, he can keep abreast of the social, economic, and legislative developments affecting medicine and health and he can actively participate in public service programs, such as night and emergency call services and health education projects which benefit his patients. A good doctor conscientiously accepts the obligation to participate in medical organizations for his patients' as well as his profession's sake. He wisely takes advantage of the many services they make available to him.

Leads on Licenses

Medical license: Obtained by examination from state board of medical examiners; National Board of Medical Examiners certificate, awarded on basis of special examination, endorsed by many states; in some states, basic science exams must be taken, others have reciprocity agreements; find out from A. M. A. how to get license; post your license in your office

Federal narcotics license: Obtained by filing with Office of the Director of Internal Revenue; some states supply narcotics prescription blanks on request; narcotics licenses must be reregistered before July 1 each year; notify Director of Internal Revenue immediately if you move your office

Hypnotic drug license: Required in some states, such as California, for regular dispensing of hypnotic drugs; check to see if this is required in your area

Professional or occupational license: Required in some areas, check with city or county clerk for information

Zoning permit: Required in some cities for locating medical office in some areas of community

Announcing a New Practice

Ethically, a physician does not advertise for patients but builds his practice in dignified ways in keeping with the ideals of his profession. Yet, he must have some means of announcing to the public and to other doctors that he has established an office and offers his services. Every community has its own customs and its own ideas about the proper way for a physician to announce his practice. In some places stories in the local newspaper are considered proper; in others, newspaper notices are considered in bad taste. Some medical societies designate the type and size of permissible sign a physician may use outside his office.

The county society can tell a new physician about local customs in this regard, even to the way in which physicians place their listing in the local phone directory. The society also will inform him of local practices regarding mailings announcing the opening of a medical office to physicians or patients and often suggest ways he can build his practice speedily. Avoid inadvertent actions flaunting local custom by checking with the medical society first.

Hospital Privileges

A physician's office practice is strengthened and stabilized with proper hospital privileges. It is important to the new physician to determine the various kinds of privileges available to him.

Once again, the county medical society can give a good idea of the types of hospital privileges available. A call on the hospital administrator and the hospital's chief of staff will provide the specific information needed. A physician may be accorded an appointment to "active service" on the hospital staff, with maximum responsibility relating to medical policy and corresponding demands on his time, or he may be offered "consulting privileges," "courtesy privileges," or "temporary privileges." Each hospital establishes its own qualifications for staff membership on the advice of its own staff members, so types of privileges will vary.

Local Public Health Obligations

Every community and state places certain obligations upon physicians in regard to public health matters. As a rule, when a physician is called in a case involving violence, he is obligated by law to inform the authorities. In the case of death by suspected violent or unlawful means, the doctor is not allowed to sign a death certificate. In routine deaths the physician should sign the certificate as soon as is reasonably possible so that legal burial may take place. In most states it is illegal for a physician to take the responsibility of sending a corpse to an undertaker unless he has been authorized by the next of kin or person responsible for funeral expenses.

A physician is obligated to local and state boards of health to report births, deaths and designated "reportable" diseases. He must also abide by quarantine regulations and in most communities must report results of premarital examinations for venereal diseases. Some states require detailed reports of stillbirths and births out of wedlock. In other states, occupational diseases must be reported within 10 days or two weeks. A great deal of useful medicolegal information, as well as a booklet of various legal forms used regularly in the doctor's office, may be obtained from the A. M. A. Legal Department.

MEDICAL FILM REVIEWS

Psychiatric Nursing: The Nurse-Patient Relationship: 16 mm., black and white, sound, showing time 35 minutes. Produced in 1958 by Dynamic Films, New York. Procurable on loan from ANA-NLN Film Library, 267 W. 25th St., New York, or Smith, Kline and French, Medical Film Center, 1530 Spring Garden St., Philadelphia 1.

The purpose of this film is to teach principles in psychiatric nursing, with emphasis on the importance of the therapeutic nurse-patient relationship in the care and treatment of the mentally ill. It is not intended to give a comprehensive picture of every role, function, or activity of all nursing personnel. Instead, it emphasizes some significant aspects of constructive nurse-patient relationships that favor the recovery and return to the community of a patient in a psychiatric hospital. In several instances, the nurse's acceptance of patient behavior is brought out and the nurse is helped to understand her own reactions and feelings and their importance in relationship to the patient. The main topic of the film is to help the nurse understand that she, as a person, can help a mentally ill patient bridge the gap from her own world to reality. This film is recommended for basic nursing programs and also in advanced nursing at the graduate level; it may also be of interest to resident physicians in psychiatry.

Biliary Duct Atresia: 16 mm., color, sound, showing time 11 minutes. Prepared by Julian A. Sterling, M.D., Philadelphia. Produced in 1957 by and procurable on loan ($3) or purchase ($60) from Ralph Lopatin Productions, 1920 Chestnut St., Philadelphia.

This film presents a treatment for biliary atresia. The infant is a few weeks old and immediately after birth presented a picture of increasing jaundice. During the operation, needle biopsies of the liver were taken; the frozen sections revealed a nondevelopment of the intrahepatic bile ducts. The surgical therapy devised is one in which an external biliary fistula is formed by the insertion of 10 silver needles into the liver lobes, mostly into the right. Roentgenograms and postoperative photographs are shown up to the 10th postoperative day. This would be more convincing if the living baby were shown months or years after surgery. At the present time, this operation is highly experimental. One might criticize the excessively long fingernails of the anesthetist shown intubating the infant. Since this picture deals with such a specialized and experimental problem, it cannot be recommended for practical audiences or as a teaching film. Its value would be in the realm of experimental surgery.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Parathyroid Crisis: A Cause of Sudden Death. J. S. Hewson. A. M. A. Arch. Int. Med. 102:199-203 (Aug.) 1958 [Chicago].

The 38-year-old man whose history is presented complained of nausea, vomiting, constipation, and a 17-lb. weight loss over a 4-week period. He had noted the onset of progressive easy fatigue 5 years prior to admission. He had been subject to severe intermittent lower abdominal pain, resembling renal colic, for 2 or 3 years. During the 6 months prior to admission, he had consumed at least 2 or 3 qt. of milk daily. A 1-cm. nodule was palpated in the region of the right lower lobe of the thyroid. In the afternoon of the day of admission some basilar rales were noted bilaterally, and the patient appeared slightly cyanotic. Later, while a consulting physician was talking with him, the patient suddenly stopped breathing and became pulseless. Cardiac massage and the intracardiac administration of epinephrine effected only transient impulses. At autopsy a large, spherical, well-encapsulated mass, measuring 5 cm. in diameter, was noted to be confluent with the right lower parathyroid gland. On microscopic examination of this mass, the typical histological pattern of a parathyroid adenoma was found, involving proliferation of chief cells with variations to the water-clear cell type. There was also some evidence of old hemorrhage. There were multiple areas of calcium deposition and secondary inflammation in the kidneys. Bone sections contained many areas of osteoclastic bone resorption, with fibrosis around trabeculae. An early confluent pneumonia was present and a moderately congested liver.

This case history is typical of the 22 previously reported instances of parathyroid crisis. In all the reported cases, an acute episode was superimposed on chronic hyperparathyroidism, evidenced by kidney stones or metastatic calcium deposits and bone changes. Kidney stones or calcium deposition may precede bone changes by several years. Since in the present case, in addition to the long history, there were renal calcifications and early osteitis fibrosa, one may assume that the patient also had chronic hyperparathyroidism. All but 3 of the 23 reported cases of parathyroid crisis were due to a parathyroid adenoma. Of these 3 cases, one was caused by overdosage with parathyroid extract; another was due to a parathyroid carcinoma; and the third was reported as frank hyperplasia. The acute phase of hyperparathyroidism, parathyroid crisis, is uncommon; it is easily misdiagnosed and may prove rapidly fatal. It is characterized by an acute exacerbation of the signs and symptoms of chronic hyperparathyroidism, with a precipitous rise in serum calcium and eventually in serum phosphorus levels. The critical level of serum calcium seems to be 17 mg. per 100 cc. A high calcium intake and/or immobilization may precipitate the crisis in a patient with hyperparathyroidism. Surgical intervention offers the best chance of survival at present, although the use of chelating agents for temporarily lowering the serum calcium level may prove an effective means of treatment in the future.

Idiopathic Hypoparathyroidism: Report of a Case. G. Halvorsen and J. G. Arbo. Tidsskr. norske lægefor. 78:628-630 (July 1) 1958 (In Norwegian) [Oslo].

The criteria for the diagnosis of idiopathic hypoparathyroidism are hypocalcemia, hyperphosphatemia, chronic tetany, normal renal function, no intestinal dysfunction, exclusion of osteomalacia, and positive Ellsworth-Howard test. In the case reported, in a man aged 64 years when first seen in 1952, all the criteria were fulfilled except one: the renal function was not normal. The renal disorder was believed to have developed recently and was possibly secondary to the main disease. From all indications the' patient had had latent tetany with sporadic attacks for more than 20 years. The bilateral cataract which he had had for several years was operated on in 1952 with good result. Treatment with calcium and calciferol resulted in normalization of the mineral metabolism and marked clinical improvement. The condition has been diagnosed as idiopathic hypoparathyroidism, which is often mistaken for epilepsy. The postoperative form of hypoparathyroidism has been excluded. At present, 16 months after discharge, the patient is far more capable of work than could have been expected at the start of treatment. He

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

has a zest for life and says that he has not been so well for more than 20 years. Urine and blood are controlled regularly, and maintenance treatment with calcium and calciferol is given.

The Endoscopic Treatment of Parenchymal Tuberculosis (A Pilot Study in the Human). A. A. Carabelli. Dis. Chest 34:162-180 (Aug.) 1958 [Chicago].

The author explored a new approach to the chemotherapy of parenchymal tuberculosis in 18 consecutive patients with pulmonary tuberculosis of various types and degrees of severity, who underwent endobronchial instillation of an oily suspension of isonicotinic acid hydrazide as a pilot experiment. All the patients underwent bronchoscopy, and the secretions obtained directly from the infected lobe or lobes by a special tubercle bacillus collector were studied by smear, culture, and guinea-pig inoculation, whenever possible. The instillation of the drug suspension was carried out with the aid of laryngotracheobronchial anesthesia and various techniques including the standard bronchoscope, an optical catheterizing bronchoscope, and bronchography. Routine complete filling of all 5 lobes was performed at the same sitting after the known diseased lobes had been filled. Most of the lobes of the lung usually tolerated 10 cc. of the suspension containing 500 mg. of isoniazid. In general, 1 to 4 instillations were required, spaced at 20-day intervals, and a total of 71 instillations were made. All but 2 of the patients received concomitant isoniazid therapy with conventional doses by mouth.

Of 14 patients whose aspirates were positive before the instillation, 12 (86%) turned negative. The average time required for conversion was 96 days. Roentgenologic examination revealed complete clearing of visible lesions in 10 (59%) of the 18 patients and complete closure of cavities in 10 patients (100%) with cavitation. The average time required for clearing of the lesions as well as closure of the cavities was 55 days. Weight gain varied from 2 to 29 lb. (0.9 to 13.2 kg.) in 14 patients; 2 patients neither gained nor lost weight, and 2 patients with diabetes mellitus lost 6 and 10 lb. (2.7 and 4.5 kg.) respectively. The isoniazid suspension was well tolerated by the parenchyma and by the host with the exception of a transient pneumonitis which occurred soon after the introduction of the suspension into the lobe. With the exception of a slight rise in temperature, systemic reactions or symptoms did not occur. Follow-up for an average period of 14 months showed that the clinical and roentgenologic results obtained were permanent.

These observations suggest that with the new portal of therapy the conversion rate becomes high and is obtained in rather short intervals. Complete disappearance or improvement of the lesions in the chest roentgenograms as well as cavity closure occurs oftener and within shorter time intervals than with conventional oral administration of antituberculous drugs alone. Isoniazid in oily suspension introduced endobronchially, has a pronounced specific lytic action on tuberculous foci. The medication and the technique of its administration are safe and free from any detrimental effects on the parenchyma or undesired constitutional effects. Lobar or multilobar drug saturation is proposed as a new concept in the chemotherapy of pulmonary tuberculosis.

ACTH-Producing Tumor of the Pituitary Gland. D. H. Nelson, J. W. Meakin, J. B. Dealy Jr. and others. New England J. Med. 259:161-164 (July 24) 1958 [Boston].

The association of adrenal hyperplasia with basophil tumors of the pituitary gland was first suggested by Cushing. This type of tumor has since been thought to be at least one cause of adrenal cortical hyperfunction (Cushing's syndrome), but no demonstration of elevated levels of corticotropin (ACTH) has been reported in the plasma of patients with this condition. The authors present a patient who, 3 years after bilateral adrenalectomy for hyperadrenocorticism, was found to have a chromophobe tumor of the pituitary that was secreting large quantities of corticotropin. The tumor could not be suppressed completely by the intravenous administration of hydrocortisone, as had been observed in other patients with adrenal insufficiency. The tumor also appeared to produce large quantities of chromatophore-stimulating hormone. After removal of the tumor the plasma corticotropin activity was not detectable, but 3 weeks postoperatively, and after additional irradiation of the pituitary gland, this activity was again demonstrated. Four months after operation plasma corticotropin activity had shown no further increase and had remained in a range that is considered normal for a patient who has undergone adrenolectomy. This case suggests the possibility that adrenalectomy acted as a stimulus to corticotropin secretion and production of a pituitary adenoma.

Pulmonary, Eventually Lethal Complications of Asian Influenza (Staphylococcus aureus) and Its Treatment. S. Moeschlin. Schweiz. med. Wchnschr. 88:655-662 (July 5) 1958 (In German) [Basel, Switzerland].

Moeschlin states that in influenza pandemics, which extend at intervals of every 30 or 40 years over the entire world, the virulence of the disease increases either gradually or suddenly. The severe or fatal cases occur chiefly during the later part of the epidemic or during a second malignant wave. This was observed in a number of places during the recent pandemic of Asian influenza. The author presents observations on the treatment of seriously ill patients, particularly those with pulmonary complications, and on the results of a prophylactic vaccination. Among 238 employees of a hospital who had been vaccinated against influenza, only 18 contracted influenza, whereas of 35 who were not vaccinated, 16 contracted the disease. Of 33 patients who were hospitalized with influenza pneumonia, 13 died, but in 2 of these death was due to another cause. Autopsy on patients who had died of pneumonia, or of acute fibrinous laryngotracheobronchiolitis, revealed the existence of a superinfection with Staphylococcus pyogenes var. aureus (sometimes combined with streptococcic and pneumococcic infections). These superinfections had been observed also by other investigators.

Patients with preexisting reduced pulmonary capacity seemed to be particularly threatened. These included patients with asthma, sarcoid of Boeck, silicosis, tuberculosis, kyphosis, severe emphysema, and pulmonary resection, as well as those with decompensated heart and diabetes mellitus. Patients with pulmonary complications should be treated early with tetracycline Achromycin) and streptomycin, and those with severe toxicity should be treated with erythromycin and novobiocin (Albamycin) which act particularly on staphylococci. These drugs should be employed in combination with prednisone and hydrocortisone. The author emphasizes that in patients with hemorrhagic fibrinous laryngotracheobronchiolitis caused by staphylococci, who have inspiratory stridor, an early prophylactic tracheotomy with bronchial cleansing is of vital importance.

Synthesis and Metabolism of Radioactive Heparin. H. B. Eiber and I. Danishefsky. A. M. A. Arch. Int. Med. 102:189-193 (Aug.) 1958 [Chicago].

This report is based on a 3-year biochemical and clinical study of heparin, the synthesis, metabolism, and fate of which have been an enigma for years. Heparin has been employed in the treatment of thrombosis. In addition to its anticoagulant action, it has been found to effect the clearance of lipemic plasma. It inhibits certain enzymes, is also involved in radiation sickness, and has been claimed to be effective in the treatment of frostbite. Heparin is a normal constituent of the animal organism, the highest concentration being found in the liver and the lung. It is a sulfated mucopolysaccharide, having a number of structural features in common with hyaluronic acid and chondroitin sulfuric acid. The exact chemical structure of heparin is still open to question; however, the most probable structure appears to be a repeating tetrasaccharide unit.

In order to solve the problems of biosynthesis, use was made of isotopic tracers. It was found that radioactive heparin could be isolated from animals to which radioactive glucose (C^{14}) had been previously administered. This indicated that glucose is involved as a precursor in the biosynthesis of heparin. In a similar manner, administration of radioactive sodium sulfate (S^{35}) resulted in the formation of radioactive heparin containing S^{35}, indicating that sulfate is also a building block for heparin biosynthesis. In other words, the intact living organism is capable of synthesizing heparin from glucose and inorganic sulfate. It appears that the optimum dosage for an adult of 150-lb. weight is 50 mg. every 4 hours when given intravenously. Larger doses would not proportionately increase the heparin effect and are unwarranted. The intramuscular route necessitates a slightly higher dosage schedule. Heparin is a normal constituent of blood in concentrations of 0.5 mg. per 100 cc.

SURGERY

Surgery of Duodenal Ulcer. R. H. Smithwick. Am. J. Gastroenterol. 30:145-160 (Aug.) 1958 [New York].

The author studied the effect of various operations for duodenal ulcer on the gastric acidity of 42 patients, as judged by the incidence of achlorhydria under fasting or basal conditions, in response to stimulation by a food substance (beef broth) and in response to vagal stimulation induced by insulin hypoglycemia. Of the 42 patients, 16 underwent posterior gastroenterostomy combined with vagotomy and only 4 (25%) of them were achlorhydric. Three (50%) of 6 patients who had the distal one-third of the stomach removed in order to eliminate the antral factor and who also had a vagotomy were achlorhydric. Eight (80%) of 10 patients who had the distal one-half of the stomach removed and who underwent vagotomy were achlorhydric in the early postoperative period, and the same result was obtained in 8 of 10 patients who had a subtotal gastrectomy and vagotomy. These results suggested that removal of less than one-half of the stomach, when combined with vagotomy, would not give a high enough incidence of achlorhydria to duplicate the protection against recurrent ulcers which a subtotal gastrectomy alone affords. Also, it did not appear that removing more than one-half of the stomach, when combined with vagotomy, increased the incidence of achlorhydria.

The physiological and clinical results in 55 patients having a hemigastrectomy combined with resection of the vagus nerves were then compared with those in 70 patients having a subtotal gastrectomy and vagotomy. With the passage of time, the incidence of achlorhydria in the 55 patients increased to 84% and compared favorably with an incidence of 66% in the 70 patients. Postoperative secretory studies were performed in the course of a 6-year postoperative follow-up period on 182 patients subjected to a subtotal gastrectomy and on 115 patients subjected to a hemigastrectomy and vagotomy. Of the patients subjected to a subtotal gastrectomy, 76 were studied for 1 or 2 years postoperatively and 106 were studied for 2 to 6 years; 36% of the 76 patients had free hydrochloric acid and 39% of the 106 patients had free hydrochloric acid. Of the patients subjected to a hemigastrectomy and vagotomy, 14% of the 87 patients who were studied for 1 or 2 years postoperatively had free hydrochloric acid and 4% of the 28 patients who were studied for 2 to 6 years had free hydrochloric acid. The longer these patients were followed, the higher became the incidence of achlorhydria. These findings suggest that there may be a gradual decrease in the secretory activity of the parietal cells with the passage of time after a hemigastrectomy and vagotomy.

A hemigastrectomy combined with vagotomy is a very satisfactory operation for the treatment of duodenal ulcer and is the author's procedure of choice. The evidence presented suggests that it will stand the important test of time. Although a longer period of observation is needed to establish this as a fact, the high incidence of achlorhydria, which appears to be increasing with the passage of time, suggests that patients who undergo this operation are rarely going to have recurrent peptic ulcers in the late postoperative period. Poor clinical results are rare, while excellent and good clinical results predominate. The incidence of severe or distressing postoperative symptoms is lower than after a subtotal gastrectomy. The results of a hemigastrectomy combined with vagotomy thus more closely approximate the ideal—cure of the ulcer, prevention of its recurrence, and leaving the patient asymptomatic—than those of any other operation for duodenal ulcer.

Cancer of the Stomach After Gastric Resection for Peptic Ulcer. R. Cote, M. B. Dockerty and J. C. Cain. Surg. Gynec. & Obst. **107**:200-204 (Aug.) 1958 [Chicago].

A clinicopathological review was made of 17 cases studied with emphasis on the pathological characteristics of the patients' stomachs at the time of resection. The series included 5 patients with carcinoma of the gastric stump, in whom resection was performed for peptic ulcer, and 12 patients with gastric cancer after simple excision of an ulcer usually with gastroenterostomy. The ulcers were usually single, gastric in location, and they appeared as ordinary chronic ulcers. None of the 5 resected stomachs that were available for study presented the picture of giant hypertrophy of the mucosa. The microscopic picture of the stomachs was characteristic; severe gastritis or duodenitis was evident in the wall surrounding the lesion. A precancerous lesion was not present in the proximal portion of any of the 5 stomachs studied. In 2 cases the interval between the evidence of gastritis and the development of cancer was 17 and 25 years respectively; in 1 case of moderate gastritis it was 12 years; and in 2 cases, in which the mucosa was normal, the interval was 6½ and 9 years respectively. The malignant lesions included sarcoma (1), hemangioendothelioma (1), and adenocarcinoma (15), the latter usually being located at the line of anastomosis in the patients who had undergone resection and in the lower part of the stomach in the others. The small number of cases available suggests that cancer of the stomach rarely develops in patients who have been treated for peptic ulcer either by gastric resection or by excision of the ulcer.

On 44 Interventions with Opened Heart under Extracorporeal Circulation. C. Dubost, P. Blondeau, C. Lenfant and others. Semaine hôp. Paris **34**:1759-1770 (June 18) 1958 (In French) [Paris].

The authors report a study on the use of extracorporeal circulation in the repair of 10 different cardiac defects in 44 patients operated on at the Marie Lannelongue Surgical Center in Paris. Eighteen patients were treated surgically with the Lillehei heart lung apparatus and the remaining 26 with the rotary disk oxygenator. Thirteen of the 44 patients died. Not a single death occurred among the 19 patients with interatrial communications, although a certain number of these patients had defects of the ostium primum type which necessitated plastic repair by means of Ivalon sponge. Other cases were complicated by abnormal pulmonary venous return and required plastic repair. The only deaths among the patients with pulmonary stenosis occurred in 4 patients with infundibular pulmonary stenosis, surgical treatment having been ineffective. The death rate was high among the patients with interventricular communications; however, the authors feel that, as experience with surgical treatment in these cases increases, less severe hemodynamic disturbances should result.

Control of Bleeding at Operation: A Trial of Adrenochrome Monosemicarbazone (Adrenoxyl). J. Calnan and F. L. F. Innes. Brit. J. Plast. Surg. **11**:87-96 (July) 1958 [Edinburgh].

The authors report the results of a blind controlled trial of adrenochrome monosemicarbazone (Adrenoxyl), which was carried out on 76 patients admitted to the Nuffield department of plastic surgery of the Churchill Hospital in Oxford, England. The trial was made in an attempt to assess the value of Adrenoxyl as a hemostatic agent. Each of 39 patients received 15 mg. of the drug by mouth and 1.5 mg. by intramuscular injection before operation, and 25 mg. by mouth after operation.

Dummy preparations were given to the remaining 37 patients. Results showed that Adrenoxyl had no effect on the amount of bleeding at operation.

GYNECOLOGY & OBSTETRICS

Sex Chromatin in the Cell Nucleus and Hormonal Treatment of Mammary Carcinoma. P. N. Ehlers and H. A. Hienz. Arch. klin. Chir. 288:485-498 (No. 5) 1958 (In German) [Berlin].

When women with carcinoma of the breast are treated with male sex hormones, some respond very favorably, whereas others do not respond at all, or the growth of metastases may even progress. In these latter cases treatment with hormones of the same sex may result in improvement. The authors used the determination of the sex chromatin body of the cell nucleus on carcinomas of the breast and on carcinomas of the prostate. They had available for study paraffin-embedded breast carcinomas from 41 women and prostate carcinomas from 10 men. It was found that in two-thirds of the women the sex chromatin in the cells of the tumor corresponded to that of the patient, whereas in the other third it was different. Thus there are women with "female" breast tumors and with "male" breast tumors. In a few cases it was possible to examine the epidermis as well as the underlying tumor for the sex chromatin. The sex chromatin in the epidermis always corresponded to the sex of the patient, but this was not always the case with the tumor. In contradistinction to mammary tumors there was never any difference in sex between the tumor and its host in the cases of prostatic tumor.

The case histories of the women with breast carcinoma were reviewed and it was found that when women were treated with male sex hormone (testosterone) those with "female" breast carcinoma responded much more favorably than did those with a "male" carcinoma. When treatment with testosterone was omitted, women with a "male" carcinoma generally had a more favorable course than those with a "female" carcinoma.

The Present Potential of Exfoliative Cytology in the Detection of Cervix Cancer. J. W. Berg and G. M. Bader. Cancer 11:758-764 (July-Aug.) 1958 [Philadelphia].

A series of 65,000 screening examinations were reviewed in order to assess the potential of cytology in cancer detection. In the years 1950-1955 there was a 72% possibility that later cytological material would be forthcoming from any women who had been given an annual examination, thus the authors were permitted not only to check the sensitivity and accuracy of their cytological diagnoses but to obtain cumulative cytological material from patients in whom cancer was expected to develop while they were under observation. When atypical cells were found on smears from the cervix directly or the vaginal pool, they were classified as follows after having been referred to physician cytologists for diagnosis: (1) indication for immediate biopsy; (2) findings needing clarification by additional smears; and (3) no indication for repeat examination until next annual visit. Of the 108 asymptomatic cervix cancers found in patients between 1948 and 1956 only 9% had a lesion that suggested biopsy at the time of examination before cancer was detected by cytology, the remaining 91% having negative findings on careful routine pelvic examination. The percentage (13%) was similar in those new patients who developed detectable cancer between clinic visits.

An error rate of 2 to 4% is ascribed to cytologists of moderate experience, while the screening error is somewhat higher (6.5%), bringing the total diagnostic laboratory error to approximately 10%. When this diagnostic error is interpreted from the standpoint of the patients and the increased mortality due to such errors it is of note that by the end of 3 years only 1 case in 1,000 would have been missed by annual cytology alone, and at the end of 5 years the error rate of 1 per 100,000 cancers is far less than the 1 missed case in the whole country every year. This error becomes increasingly smaller with repeat examinations since the data suggest that the average in situ cancer exfoliates diagnostic cells for 8 or more years before it becomes invasive. About 90% of the patients with early stage 1 invasive lesions may expect a 5-year survival. Thus, the only women who need fear cancer are those few whose cancers are so atypical that they will escape recognition on 10 or more cytological smears, and when cervical cytology is included in an annual examination of cancer-free women, deaths from cervix cancer should be almost wholly preventable.

The Treatment of Tuberculous Salpingitis. Å. Rydén. Acta obst. et gynec. scandinav. 37:114-130 (No. 2) 1958 (In English) [Stockholm].

The author reports on 122 women with tuberculous salpingitis who were treated at 2 Swedish hospitals between 1947 and 1957. Of 47 patients with antecedent extrapulmonary tuberculosis, 34 had tuberculous peritonitis, 4 had tuberculosis of the kidneys, 1 had intestinal tuberculosis, and 8 had tuberculosis of the bones and joints. Eighty-three patients had adnexal mass as revealed by palpation, and 39 did not have it. Forty-seven patients were asymptomatic, 42 had pain, and 33 had menstrual disturbances. Antituberculosis drug therapy was given to all patients. The drugs used included streptomycin, aminosalicylic acid, amithiozone (Conteben), and isoniazid. Combined treatment with 300 mg. of isoniazid and 12 Gm. of aminosalicylic acid daily, using streptomycin only for preoperative and postoperative treatment when required, was found to be expedient. Antituberculosis drug therapy was followed by surgical treatment in 55 patients. Of 30 patients who received antituberculosis drug therapy for 4 to 6 months followed by partial or complete removal of the fallopian tubes, 17 did not show any evidence of tubal lesions on microscopic examination of the surgical specimen, but tuberculous tubal lesions persisted in the remaining 13. Some of the 13 patients were asymptomatic. In none of the patients treated conservatively did intrauterine pregnancy occur. Of 2,118 women with genital tuberculosis whose cases were collected from the literature and who were treated conservatively, intrauterine pregnancy proceeding to term occurred in 48. Since both tubes may be occluded in 50 to 70% of patients with tuberculous salpingitis at the time of diagnosis and since antituberculosis drug therapy resulting in cure of the tuberculous tubal lesion is not likely to achieve also patency of the tubes, it may be assumed that intrauterine pregnancy follows antituberculosis therapy in 30 to 50% of the patients in whom one or both tubes are patent at the time of the institution of the treatment.

The introduction of antituberculosis drugs, inhibiting the growth of tubercle bacilli, marks an outstanding advance in the treatment of genital tuberculosis in women. In those patients who require surgical treatment, preoperative and postoperative antituberculosis drug therapy lessens the operative risk and lowers the incidence of postoperative complications. Antituberculosis drug therapy alone will probably result in cure of tuberculous salpingitis if it is given for a period of 1 year or more. The present routine treatment for 6 months is generally too short to result in cure of tuberculous salpingitis. Surgical treatment combined with preoperative and postoperative antituberculosis drug therapy should be the routine method of treatment of patients with tuberculous salpingitis unless drugs may be discovered which are superior to those now in use. Women with asymptomatic genital tuberculosis in whom roentgenologic examination shows 1 or both tubes to be patent should be given first a trial of antituberculosis drug therapy alone, because those in whom this treatment is successful have a chance of conceiving and bearing a live child. The tuberculous lesions may, however, cause lasting infertility in most patients.

Acute Salpingitis: Views on Prognosis and Treatment. E. Hedberg and S. O. Spetz. Acta obst. et gynec. scandinav. 37:131-154 (No. 2) 1958 (In English) [Stockholm].

The authors report on 216 women with acute salpingitis who were treated between 1946 and 1953. Ninety-six patients had gonorrheal salpingitis with positive cultures of gonococci obtained from the cervix, the urethra, or the rectum. The remaining 120 patients were classified as having septic salpingitis. All patients had reached puberty and menopause had not yet occurred in any. The average age of the patients with gonorrheal salpingitis was 26 years, and that of the patients with septic salpingitis was 28 years. Unmarried women predominated in the group with gonorrheal salpingitis, and most women in the septic group were married. About 60% of all the patients had had previous abortions or deliveries. The onset of salpingitis occurred at the time of menstruation in 65 patients (68%) with gonorrheal salpingitis and in 46 (38%) of those with septic salpingitis. Septic salpingitis occurred in 28 patients (23%) with abortions or intrauterine instrumentation, but gonorrheal salpingitis occurred in only 6 such patients (6%). Fever or rigors occurred in 63 (52%) of the septic group and in 69 (72%) of the gonorrheal group. Nausea and vomiting were frequent symptoms and menstrual disorders, mainly menometrorrhagia, occurred in 30% of all the patients. Unilateral or bilateral adnexal swellings occurred in 80% of the patients. Pathological adnexal tenderness was observed in 15 (13%) of the patients with septic salpingitis and in 21 (22%) of those with gonorrheal salpingitis. The erythrocyte sedimentation rate was increased and exceeded 20 mm. in 1 hour in about 90% of the patients, and it exceeded 40 mm. in 1 hour in 45%. The high erythrocyte sedimentation rates predominated in the septic group.

All patients with gonorrheal salpingitis received adequate antibiotic treatment with 800,000 I.U. of a combined preparation of benzathine, potassium, and procaine penicillin G (Astracillin) for 5 days. Only 13% of the patients with septic salpingitis were treated with sulfonamides and 22% received 2 cc. of a combined preparation of procaine penicillin G and dihydrostreptomycin (Streptopenin) twice a day for 5 days. Patients who on admission had reached the subacute or chronic stage, did not receive this treatment. The average duration of hospitalization was 40 days for the patients with septic salpingitis and 26 days for those with gonorrheal salpingitis. One hundred ten patients (92%) with septic salpingitis and 71 (74%) of those with gonorrheal salpingitis were followed up. Relapses requiring rehospitalization, occurred in 10 patients (9%) with septic salpingitis and in 11 (15%) of those with gonorrheal salpingitis. Ten patients with septic salpingitis and 4 with gonorrheal salpingitis required surgical treatment during the follow-up period because of severe residual lesions. The effect of antibiotic therapy completely depends on the length of time which elapses between the onset of symptoms and the institution of treatment, and the immediate and late prognosis also depends on this interval. The effect of antibiotic therapy on acute salpingitis concerning subsequent pregnancy in these patients as compared with that in patients previously reported on by other workers, consisted in notable improvement. Among the 181 patients who were followed up, the incidence of pregnancy was 30%. After corrections for voluntary sterility, age above 40, and marital status, the incidence of pregnancy for the entire series was 60%. The effect of antibiotic therapy concerning subsequent fertility was most pronounced in the patients with gonorrheal salpingitis. A supplementary examination by hysterosalpingography in 30 patients with gonorrheal salpingitis performed on discharge from hospital showed tubal patency in 24 (80%) of them.

DERMATOLOGY

The Long-Term Results of the Treatment of Early Syphilis. L. Chargin, N. Sobel, J. E. Vandow and T. Rosenthal. Acta. dermat.-venereol. 38:168-172 (No. 2) 1958 (In English) [Stockholm].

The authors report the results of long-term observations on 72 patients, 29 of whom had primary syphilis and 43 had secondary syphilis, who were given a minimum of 20 arsenical and 20 bismuth injections at the clinics of the New York City Department of Health. Some patients received as many as 50 arsenical and 50 bismuth injections. The minimum post-treatment observation period was 5 years, but in many patients it was up to 10 years. The final status of these patients was as follows: 18 (62%) of the 29 patients with primary syphilis were seronegative and 11 (38%) were seropositive; 27 (63%) of the 43 patients with secondary syphilis were seronegative, the remaining 16 (37%) were seropositive. None showed any abnormal physical findings. Positive spinal fluid findings indicative of asymptomatic neurosyphilis were found 1 to 5 years after treatment in 8 of the 72 patients. The over-all cure rate was 62%.

In 1946 when penicillin became available, the New York City Department of Health began to use it in the treatment of syphilis. Fifty patients, 27 with primary syphilis and 23 with secondary syphilis were treated with 6 to 9 million units of penicillin alone and were followed up for 5 to 11 years. Of the 27 patients, 24 were found to be clinically and serologically negative; 3 patients were still seropositive, although physical examination gave negative results. Of the 23 patients treated, 15 were clinically and serologically negative; 7 were serologically positive, although they were negative on physical examination. One patient had asymptomatic central nervous system syphilis. The reported data prove that in early syphilis penicillin is by far the most effective and safest remedy for producing a cure, as well as preventing the late damaging manifestations of the disease.

Pemphigus Seborrheicus (Senear-Usher Syndrome, Pemphigus Erythematosus). L. Chargin, H. Silver and P. M. Sachs. Acta dermat.-venereol. 38:137-144 (No. 2) 1958 (In English) [Stockholm].

The authors report on a 58-year-old man with a syndrome combining features of pemphigus, lupus erythematosus, and seborrheic dermatitis. An eruption consisting of isolated erythematous patches, varying in size from a bean to a penny, some crusted, some scaly, and some suggesting bullae, appeared in 1955 after a sunburn. The lesions were at first limited to the chest. A year later they appeared on the face and scalp. There were no subjective symptoms present. The patient has been well controlled with corticosteroid therapy and there have been intervals of almost complete freedom from eruption. A positive Nikolsky sign could be elicited. The patient's general health remained good. Laboratory tests including blood cell count, urinalysis, and chemical examination of the blood showed no abnormal findings. The histological examination showed dilated superficial vessels and about them a focal and diffuse reaction composed of small, round, and wandering connective tissue cells. There were also some polymorphonuclear leukocytes and eosinophils and these were particularly evident in the lumen of the papillary capillaries. In the upper epidermis, in the area of the granular layer, eosinophils were also present. On the surface, some areas showed crusting with numerous polymorphonuclear leukocytes. These findings were essentially those seen in pemphigus.

In 1926 Senear and Usher reported 11 cases of a syndrome similar to that observed in this patient. The variability of the clinical picture of the Senear-Usher syndrome has led to a variety of interpretations of the affection. The diagnosis in many patients cannot be made solely on clinical grounds. However, the type of lesion, the location, the course, and particularly the help furnished by the pathological findings make a diagnosis possible in most of them. The pathological features in most patients are essentially those of pemphigus. The conclusion seems warranted, therefore, that Senear-Usher syndrome is, in fact, a form of pemphigus with special features. The special features are the location of the eruption in seborrheic areas, thus the term pemphigus seborrheicus is to be preferred.

THERAPEUTICS

Anticoagulation Treatment. P. A. Owren. Tidsskr. norske lægefor. 78:571-578 (June 15) 1958 (In Norwegian) [Oslo].

All anticoagulant treatment is in its nature prophylactic and should be introduced at an early stage. Permanent anticoagulant treatment affords protection against renewed embolization in patients with rheumatic heart disease, considerably reduces the mortality in myocardial infarction, and has a marked prophylactic effect in angina pectoris if the interval between diagnosis and treatment in angina pectoris is less than a year. The treatment has little if any effect on the mortality in patients with angina pectoris of more than 2 years' duration before treatment. Seventeen patients with rheumatic heart disease who had had recurrent thromboembolic episodes before treatment were given anticoagulation treatment for an average of 3.2 years; only 1 embolic episode occurred during the treatment. In a control group of 17 patients observed for the same length of time 20 recurrent major episodes were seen. No episode occurred in 15 patients who had had anticoagulation treatment for an average of 3 years after the first embolic episode. In the 308 patients with myocardial infarction on permanent anticoagulation treatment for an average of about 3 years the average annual mortality was 4.85%, which is about half the mortality in similar untreated groups. Comparison of the survival curves of the treated group and control groups showed 85% survival in the treated group as against 50-55% in the control groups. In the 471 patients with angina pectoris treated for an average of about 3 years the average mortality was 3.5% annually, less than one half the mortality in similar groups not given anticoagulant treatment.

ANESTHESIA

Electroencephalography as an Objective Method of Controlling the Depth of Anesthesia. A. N. Bakulev and S. N. Efuni. Khirurgiya 34:21-26 (No. 6) 1958 (In Russian) [Moscow].

One of the most important problems in anesthesiology is the objective evaluation of the action of anesthetics. For that purpose the authors employed electroencephalographic control of the depth of anesthesia. Twenty-six patients were observed under ether anesthesia. Regular changes of cerebral biocurrents were detected, depending on the stage of anesthesia. It was noted that the changes are found in the electroencephalographic curve before it is possible to detect any clinical signs. A case is presented of an overdose of ether, which was registered by the electroencephalographic method much earlier than it was manifested clinically. At times disorders in the anesthetic apparatus were promptly removed as a result of timely electroencephalographic signals. This method is valuable and has future possibilities, especially in the employment of relaxants.

PUBLIC HEALTH

Serological Response of Infants to Poliomyelitis Vaccine. F. T. Perkins, R. Yetts and W. Gaisford. Brit. M. J. 2:68-71 (July 12) 1958 [London].

Eighty-eight mothers and infants were investigated in order to determine the relationship between maternal serum and umbilical cord levels of poliomyelitis neutralizing antibodies, the rate of loss of maternally transmitted antibodies in the infants, and the response of the infants immunized at different ages with poliomyelitis vaccine. The infants were first immunized at 1, 6, and 10 weeks respectively. Only 4 infants were triple negative, having no antibodies to any of the 3 types, while 55 had antibodies to all 3 types. With all 3 types the titers of the cords and mothers' serums were similar. The loss of the maternal antibodies was similar for each type in each age group. Approximately 70% were lost at 6 weeks, and 90% at 10 weeks, suggesting that the maternal antibody level was halved every 21 days. Only a small proportion of the infants responded to the vaccine, 12.5% responding to type 1, 47% to type 2, and 36% to type 3. The degree of response on the part of the infants was proportional to the decrease in the maternal antibody level. The latter effect varied somewhat according to type. With type 1 no infant with a maternal antibody titer greater than 1:16 responded, whereas a response was given by 10 of the 32 infants with a titer of less than 1:16. With type 2 no infant with a titer greater than 1:512 responded, although a response was elicited in 40 infants with a titer less than 1:512, and with type 3 no infant with a titer greater than 1:64 responded, whereas a response was forthcoming in 32 of 58 infants with a titer of less than 1:64.

A consideration of all age groups reveals that, for all 3 virus types, the older the infant the greater the number with lower maternal antibody levels at the time of vaccination. As the proportion of infants with low maternal antibody levels increased, there was a corresponding increase in the proportion of infants responding to immunization. This increase was not entirely due to the concomitant decline in the maternal antibody levels but appeared to a certain extent to be a function of age, as in the case of types 1 and 3 where the older infants gave a much better response to vaccination. No such pattern of response was evident with type 2. In order to avoid the inhibiting effect of the maternal antibodies, it is suggested that immunization be delayed until 6 to 9 months after birth, although it is not certain whether the response to types 1 and 3 will be adequate even at this age. Studies are in progress to determine the earliest age at which the response to all 3 types will prove satisfactory.

BOOK REVIEWS

Skin Grafting. By James Barrett Brown, M.D., Professor of Clinical Surgery, Washington University School of Medicine, St. Louis, and Frank McDowell, M.D., Associate Professor of Clinical Surgery, Washington University School of Medicine. Third edition. Cloth. $15.00. Pp. 411, with 334 illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W. C. 1, England, 1958.

This excellent textbook has been completely revised. More is included than the title implies. Actually, it deals with the methods and application of the closure of surface defects arising from burns, traumatic avulsions, radiation injuries, and reconstruction of wounds after surgical removal of large tumors. Excellent chapters on the care of burns cover even the minutest detail. Different types of skin grafts and flaps are discussed. Methods of their cutting and application and their indications are shown. Special chapters deal with the repair of the hand and major joint injuries that involve skin or pedicle flap replacement. Repair of eyelid, orbit, neck, and nasal skin defects are well demonstrated. One chapter deals with homografts and a skin bank. Plastic surgeons are called on to remove many large benign and malignant skin tumors. Many of these have been complicated by injudiciously prolonged radiation therapy. All of these lesions must be removed surgically, and the authors show how the resulting defects can be reconstructed. This is an excellent reference book that should be useful to all plastic surgeons and other surgeons whose practices involve skin grafting procedures. It can also be recommended for all hospital medical libraries.

The Medical Assistant: A Guidebook for the Nurse, Secretary, and Technician in the Doctor's Office. By Miriam Bredow, Dean of Women, Eastern School for Physicians' Aides, New York. Cloth. $7.50. Pp. 430, with illustrations. Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England; 253 Spadina Rd., Toronto 4, Canada, 1958.

This guidebook contains much of the material previously appearing in the author's book, "The Medical Secretary," but places greater emphasis on such duties as sterilization of instruments and equipment, physical therapy, laboratory techniques, special tests, principles of medication, and injection techniques. Several chapters are devoted to medical secretarial duties, such as maintaining medical and financial records, insurance, and office housekeeping. The author points out that, since about 75% of all physicians today employ one or more aides in their offices, an all-inclusive manual covering the entire range of situations in which the assistant may be called on to help the doctor in general practice, as well as in special fields, and in the laboratory and the x-ray department is needed. In addition to basic theoretical information, the volume attempts to teach an untrained medical assistant what to do, how to do it, and why it is done.

Garrè-Stich-Bauer Lehrbuch der Chirurgie. Vollig Neurbearbeitet von R. Stich, o.o. Professor fur Chirurgie an der Universität Göttingen, und K. H. Bauer, o.ö. Professor für Chirurgie an der Universität Heidelberg. Kapital Anesthesie von R. Frey, a.pl. Professor fur Anaesthesiologie an der Universität Heidelberg. 16./17. edition. Cloth. 78 marks. Pp. 934, with 670 illustrations. Springer-Verlag, Reichpietschufer 20, Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, Germany, 1958.

This is an authoritative work, brought up to date by surgeons of mature experience and known technical ability. It encompasses the entire field of surgery. The fact that this is a 17th edition bespeaks its popularity. All previous editions appeared prior to World War II, after which many new techniques and surgical procedures came into use. The text is preceded by an introduction on the history of surgery. The subject matter includes general traumatology, general surgery of the locomotor apparatus, and general aspects of tumor pathology. While this is a textbook on general surgery, the specialties insofar as they come under the observation of the general surgeon have not been neglected. Extraneous, controversial, and theoretical matters have been eliminated. The authors have endeavored to present only the essentials of the practice of surgery in its modern aspects. The young surgeon and even advanced surgeons should find here an excellent medium for gaining current knowledge of accepted practice. The illustrations are excellent, the bibliography comprehensive, and the paper and binding of the splendid quality characteristic of the publisher's reputation. This work is highly recommended to all who understand German.

First Aid for Your Infant and Child. By Eric Northrup. With introduction by Morris Fishbein, M.D. Cloth. $3.95. Pp. 320, with illustrations by Dan Noonan. Henry Holt & Company, 383 Madison Ave., New York 17; George J. McLeod, Ltd., 73 Bathurst St., Toronto 2B, Canada, 1958.

Almost encyclopedic in nature, this volume covers virtually every accident and sickness situation that could occur in the home or community. Suc-

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

cinct advice is given on first-aid measures appropriate for specific situations, and there is special emphasis on the importance of evaluating the emergency before rushing in with some first-aid procedure just to be doing something. Part one deals with basic principles. The first chapter discusses the basic situation encountered when an emergency strikes. Another has a helpful discussion of how to prevent childhood accidents. First-aid implements are explained, with numerous helpful illustrations. General home care of the sick child is described, and there is a brief discussion of how to cooperate most effectively with the family physician. Discussions in the second part deal concisely with diseases and situations; these are listed alphabetically. The guidance can be considered sound and helpful, but there is some suggestion that the author has been tempted to aim at too extensive coverage. It is doubtful that such conditions as brucellosis or Q fever can be considered emergency matters or disorders with which parents can be expected to become familiar. Most recent thinking regarding "athlete's foot" has not been included. There is an excellent section on poisoning, good guidance regarding immunization, useful material on communicable diseases, and a wealth of sound advice on immediate care after a fracture or similar trauma. The volume should be of great value in the average home. Numerous helpful illustrations are included.

Clinical Orthopaedics. Number Eleven: Orthopaedic Surgery in the Geriatic Patient. Anthony F. DePalma, editor-in-chief. With assistance of associate editors, Board of Advisory Editors and Board of Corresponding Editors. Cloth. $7.50. Pp. 257, with illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W. C. 1, England, 1958.

This volume in size and format is similar to the previous volumes in this series. Its seven articles deal in generalities, and there is nothing really new in them. The first chapter is a historical biography of James Knight; it covers his influence and direction in the formation of the Hospital for the Ruptured and Crippled. It is well written and makes interesting reading. The section on general orthopedics consists of 16 articles. Some of these are reviews, and some describe new operative procedures. One of the outstanding articles is the review of eccentro-osteochondrodysplasia. The chapter on juvenile osteochondrosis also deserves praise. The section labeled "Items" consists of nine articles, most of them brief—some of them too brief and some of questionable value. In general, the reproduction of roentgenograms is not up to the usual standard of these volumes. Many of them are fuzzy, and their details are difficult to see. There are several typographical errors. This volume seems to be a little flat when compared to many others in the series, and it is hoped that future volumes will again be outstanding.

Handbuch der speziellen pathologischen Anatomie und Histologie. Herausgegeben unter Mitarbeit hervorragender Fachgelehrter von O. Lubarsch †, F. Henke †, und R. Rössle †. Band 13: Nervensystem. Herausgegeben von W. Scholz. Teil 2, Bandteile A un B: Erkrankungen des zentralen Nervensystems II. Bearbeitet von R. Bieling et al. Cloth. 859.50 marks. Pp. 1325; 1327-2902, with 565; 634 illustrations. Springer-Verlag, Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, Germany, 1958.

A previous book of this series (THE JOURNAL, May 21, 1955, page 238) dealt with the pathological anatomy and histology of injuries and tumors in the central nervous system. The two books now presented are designated as part-volumes (Bandteile) A and B of the second part (Teil) of the 13th volume (Band) of the series. This explanation seems desirable for the sake of orientation in this gigantic series, which is planned to cover the entire field of special pathological anatomy and histology. Part-volume A deals with the pathological anatomy and histology of the nonspecific forms of meningitis, virus diseases of the central nervous system, multiple sclerosis, and the changes (especially in the brain) associated with intoxications, syphilis, and other systemic diseases. These sections are contributed by 28 authors, mainly in German, but the section on the general histopathological aspects of some viral encephalitides is in English, while the sections on encephalitis lethargica and on African trypanosomiasis are in French. Part-volume B consists of contributions by six authors, all in German, on changes of the central nervous system in diseases of the heart, lungs, kidneys, liver, and blood; funicular disease (subacute combined degeneration) of the spinal cord; kernicterus; reactions of the central nervous system to metabolic and endocrine diseases; nonartiosclerotic calcification of cerebral vessels; intoxication by exogenous and endogenous poisons; deficiency diseases; and chronic progressive bulbar paralysis, chronic progressive external ophthalmoplegia, and myotrophic lateral sclerosis. The style of the individual sections deserves comment, for it stands in welcome contrast to the ill-assimilated, incoherent citations of literature that have sometimes been published as reviews. The contributors have organized their material to make a readable textbook. The illustrations are numerous and of excellent quality. The bibliographic lists are exhaustive and accurate. There is an author index as well as a subject index, and both show signs of having been prepared with extraordinary care. These two volumes constitute a priceless summary of existing knowledge. They should be of lasting value in every library used by pathologists and neurologists.

QUESTIONS AND ANSWERS

OBESITY IN A YOUNG CHILD

To the Editor:—*A girl, aged 9½, is approximately 20 lb. (9.1 kg.) overweight, and there seems to be no way to control her weight gain. She is an only child and is "spoiled," and it is difficult to talk with her about her problem. A lot of her overeating is probably due to nervous tension. She was sent for four weeks to a girls' camp, with the idea that it would enable her to adjust to group living, but unfortunately the camp did not have a diet table for the junior members. Hence, she returned home weighing about what she did before. Appetite suppression methods, such as the use of phenmetrazine hydrochloride and other similar drugs, have been tried, but she will not take the medicament regularly. Neither will she stay on a reduction diet—both factors are no doubt due to a lack of firmness on the part of her parents. Are there any camps or institutions (not hospitals) where she might go to learn the rudiments of weight reduction? Putting her in a hospital would not be the solution, because immediately on discharge she would resume her previous overeating. As she approaches puberty she will no doubt want to lose weight, but that time is several years away.*

James L. Wade, M.D., Parkersburg, W. Va.

Answer.—This question is a relatively common one. Assuming that no endocrinopathy exists (this is a fair assumption from the description), it is assumed that her overweight is related to overeating, ascribed as "due to nervous tension." Usual dietary advice and appetite suppressing methods are notoriously unsuccessful in children. It is generally more appropriate to view the overeating as a symptom which is serving some psychological need of the child. It would, therefore, be somewhat inappropriate to focus directly on dietary limitation without attempting to provide an opportunity for the child to work through some of her problems relating to need for excessive food intake. In other words, if the child is pushed to relinquish the symptom before adequate preparation has been undertaken, it is conceivable that other psychological difficulties might occur which might be more formidable than that of overeating. For this reason, one would not look toward camps or institutions of any kind to really be effective unless a psychotherapeutic approach was incorporated into the program under the direction of qualified professional personnel. The alternative to the various questions raised concerning management would be directed toward having the child seen by a qualified child psychiatrist who would be in a position to provide an evaluation and, hopefully, therapy. Although in some geographic locations it is extremely difficult to obtain such consultation, it would be worth making the effort. This recommendation is emphasized, since the suggestion is made that as she approaches puberty "she will no doubt want to lose weight." This may be the case, but one not uncommonly sees an accentuation of the problem rather than an alleviation of it with the approach of puberty. In rare instances, the child approaching puberty reacts to obesity by the development of extreme anorexia, in the form of anorexia nervosa, which, if it occurs, is a more serious problem. While the latter is not a likely possibility, it underscores the importance of competent psychiatric consultation. It should also be stated that, although the parents are very interested in their child's problem and in alleviating it, they are also much too close to it to provide the objectivity and therapeutic help which is necessary. Probably the best comprehensive resource on this subject is the recent book of Hilda Bruch, "The Importance of Overweight" (New York, W. W. Norton & Company, Inc., 1957).

TREATMENT OF TEAR GAS EXPOSURE

To the Editor:—*What counteragents and alleviating measures should be used in the immediate treatment of the symptoms (lacrimation, asphyxia, and burns) caused by exposure to the released commercial tear-gas currently used by law-enforcement officials? What follow-up regimen is indicated in the subsequent handling of patients who have come in contact with this substance?*

Charles D. Humberd, M.D., Barnard, Mo.

Answer.—Ordinarily no treatment is required after exposure to the type of tear gas used by police. Even when the person remains in a contaminated atmosphere, the effects gradually disappear after about 15 minutes. The chief lacrimators act to destroy the sulphydryl enzymes of the eye. The transient effect probably is due to the renewal of these enzymes. Currently, a common tear gas is derived from a mixture of chloracetophenone, chloropicrin, and chloroform. Other lacrimator powders or liquids leading to gases are chloracetophenone, benzyl

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

bromide, bromacetophenone, benzal chloride, bromobenzylcyanide, methyl iodoacetate, ethyl acetate, chloropicrin, acrylic aldehyde, allyl disulfide, phenylcarbylamine chloride, and osmium tetroxide. Some of these are effective as lacrimators in concentration as low as 1:100,000,000. If exposure concentration is high, superficial corneal erosions and occasionally deep opacification of the corneal stroma and edema of the cornea may appear. Even so, no permanent disability is prospective. If the powder or liquid that leads to tear gas directly enters the eye, deep central corneal ulceration may occur and opacities may be a consequence. The mucosa of the respiratory tract may be irradiated, resulting in tracheitis and bronchitis. The rare fatalities have been attributed to pulmonary edema. All of the common lacrimator chemicals may act as skin irritants with the severity of response being in proportion to the concentration of exposure. If any treatment be in order after ordinary exposure to any tear gas, prompt and free lavage with water constitutes the initial step. When chloracetophenone is the offender, which is prone to be the case because of its wide availability for use, treatment may rely upon sodium sulphite, 0.4 Gm. in 25 cc. of water and 75 cc. of glycerine. The mild dermatitis may be expected to disappear with or without treatment, but wet dressings with boric acid may speed recovery. The asphyxia mentioned in the question relates to pulmonary edema, for which oxygen therapy may be required along with the judicious application of bronchodilators and measures conducive to dehydration.

LECITHIN IN THE DIET

To the Editor:—*Please give information on lecithin. Can one use too much?*

Alice S. Cutler, M.D., Los Angeles.

Answer.—Lecithin is a phosphatide. It is also called phospholipid, a descriptive term which implies a phosphorus containing lipid. There is an excellent book on the subject entitled "The Phosphatides," by Wittcoff (American Chemical Society Monograph 112, New York, Reinhold Publishing Corporation, 1951). The phosphatides are present in all living cells, both plant and animal; this suggests their importance in body economy. Because of lecithin's natural emulsifying properties and ready availability, one of its principal uses is as an ingredient in foods. Evidence of the safety of lecithin is found in the fact that it is included in standards of identity developed by the Food and Drug Administration for the guidance of the food industry. In a recent report, Morrison (*Geriatrics* 13:12, 1958) prescribed relatively large doses of lecithin, consisting of two tablespoons three times daily over prolonged periods. Fifteen of 21 patients tolerated this large dose, while in 6 it was necessary to reduce or to discontinue use of lecithin. For a long time, lecithin has been used in the United States and in Europe as a food supplement. The reasons are chiefly empirical in the sense that they are the result apparently of group experience reported from person to person by word of mouth over a period of years. At the present time, there is a great deal of scientific interest in the phosphatides and much research is in progress. While lecithin may be regarded as a completely nontoxic, wholesome food ingredient, it is probable, as in the case of all other food ingredients, that excessive use is undesirable. However, the possibility of using lecithin to excess is unlikely, due to its relatively high satiety value. When taken in excessive amounts it tends to cloy the appetite and even to induce nausea. This effect serves as a safety device.

ANTICOAGULANTS

To the Editor:—*When anticoagulants are being used constantly, do they produce any damage to body organs? Do antihistamines have any effect on the efficiency of the anticoagulant? Does aspirin have any influence on the prothrombin level when anticoagulants are being used?*

M.D., Illinois.

Answer.—No untoward effect of heparin has been observed other than hemorrhage. This is also true of bishydroxycoumarin and other compounds of the coumarin type. A few instances of agranulocytosis developing after phenindione was given have been reported (Brown and MacMillan, *Am. J. M. Sc.* 227:526, 1954). There is no evidence that the anticoagulants now in common use injure the liver or kidney, even after long-continued use. Antihistamines do not directly affect the efficiency of the anticoagulants. They could conceivably act in a synergistic manner if the bleeding is the result of an allergic reaction, but clinical or experimental proof is lacking. Aspirin may cause a small elevation of the prothrombin time, and it has been observed that a patient on a maintenance dose of bishydroxycoumarin or a related drug with a fairly constant prothrombin time may have a significant increase when aspirin is taken. No thorough clinical study of the relationship of aspirin to the coumarin derivatives can be found in the literature.

FETAL BLOOD LOSS WITH PLACENTA PREVIA

To the Editor:—*Has any work been done on determining the amount of blood loss to the fetus in a case of placenta previa?*

J. F. Schneider, M.D., Fargo, N. D.

Answer.—Greenhill (Obstetrics, ed. 11, Philadelphia, W. B. Saunders Company, 1955, p. 470) says that, during cesarean section, which is now frequently used in cases of placenta previa, if the placenta must be incised the umbilical cord should be clamped immediately to prevent any loss of the child's blood. This should be done before the child is extracted. Greenhill says:

Wiener called attention to severe anemia of the newborn caused by unapparent hemorrhage from the fetal surface of the placenta. Wickster reemphasizes the role of posthemorrhagic shock in the death of the newborn in the presence of vasa praevia, placenta praevia and abruptio placentae. Abruptio placentae and placenta praevia not only cause fetal and newborn death by asphyxia, interference with nutrition and excretion, toxicity and prematurity but also by anemia due to rupture of the capillaries in the cotyledons. Every infant born of a patient with placenta praevia, abruptio placentae or abnormal placenta should be followed by repeated hemoglobin, cell volume and erythrocyte counts. When posthemorrhage anemia and shock are severe, 10 ml. of blood per pound of the infant's body weight should be immediately drawn from the mother, if Rh positive, and given to the infant through the umbilical, medial malcolar or temporal vein. If the mother is Rh negative, plasma should be given to the baby until Rh negative blood is secured. While this is being done the infant should be supported with oxygen.

Novak does not believe that occult or manifest bleeding in the newborn during delivery is rare. Among 879 cesarean sections there were twenty-eight placentas which were cut or torn during operation; eleven of the babies had posthemorrhagic shock. The fate of babies with posthemorrhagic shock varies; some die at once and others who are in mild shock have an aggravation of the shock if proper therapy by transfusion and oxygen is not given.

SKIN ABSORPTION OF CALORIES

To the Editor:—*Is it possible to absorb through the pores any appreciable amount of calories (from grease) from fumes in a restaurant kitchen? An obese cook gives this as his alibi for failure to reduce on a limited diet.*

P. W. Van Metre, M.D., Rockwell City, Iowa.

Answer.—This consultant is unaware of any reports in the literature indicating that the greasy atmosphere of a restaurant kitchen has any effect on weight. One would guess that the obese cook was sampling a little too freely of his wares between his regular meals, and his "theory" of absorbing extra calories through his skin should be taken with one or two pounds of salt. It just isn't so.

PENICILLIN AND TETANUS

To the Editor:—*Is it true that penicillin affords reasonable prophylaxis against tetanus? It has been said that penicillin can be used as an alternate in patients who are highly allergic to the tetanus antitoxin and in whom use of the latter might cause a severe reaction.*

T. G. Biggs Jr., M.D., Oak Grove, La.

Answer.—Penicillin is not a reliable substitute for specific prophylactic agents (toxoid and antitoxin) in the prevention of tetanus. This statement is made with due recognition of the encouraging experimental results reported by Taylor and Novak (*Ann. Surg.* 133:44, 1951). Penicillin does not neutralize the toxin of tetanus. Too many physicians entertain the erroneous belief that systemically administered penicillin is a reliable prophylactic agent against clinical tetanus in human subjects. The medicolegal implications attendant on the isolated use of local penicillin prophylaxis, to the exclusion of specific agents (toxoid or antitoxin, singly or combined, as indicated) are too broad to recommend the exclusion of the more specific techniques, already tested both experimentally and clinically, in favor of a method in the format of laboratory investigation. To repudiate tetanus antitoxin and toxoid in favor of penicillin would be a serious mistake—at least in the present state of knowledge. This consultant has had the opportunity to see fatal clinical tetanus supervene in a child given multiple large doses of penicillin promptly after a compound fracture of the arm. This took place because the parents misinformed the physicians concerning the history of tetanus toxoid injections; this led to the use of a "booster" injection of tetanus toxoid instead of tetanus antitoxin.

AURICULAR FIBRILLATION

To the Editor:—*Nothing is ever mentioned in the literature about attempting to return to normal sinus rhythm from the irregularity of auricular fibrillation, except a statement in "Clinical Heart Disease" by Levine (ed. 5, Philadelphia, W. B. Saunders Company, 1958, page 326) "that there is a temporary slowing of the ventricles by the vagal stimulation of carotid sinus pressure, with return of the original rapid grossly irregular rhythm." Have there been any instances where paroxysmal atrial fibrillation was affected by carotid sinus stimulation, or is this impossible to accomplish?*

William Schwartz, M.D., Fall River, Mass.

Answer.—It is true that little indeed has been written in the modern literature on carotid sinus pressure as a means of stopping a paroxysmal auricular fibrillation. In the experience of this consultant, and he believes it is the experience of most cardiologists and internists, pressure or massage of the carotid sinus is a completely ineffectual method of treatment for the arrhythmia in question. On the other hand, in supraventricular tachycardia, atrial or nodal, it is a routine procedure and it is often successful.

ALOPECIA AND WARFARIN SODIUM

To the Editor:—*A 77-year-old woman who has been taking digitoxin for the past two years and warfarin sodium for the past three months is rapidly losing her hair. What will remedy this condition?*

Hilmer R. Schmidt, M.D., Rushford, Minn.

Answer.—Digitoxin would have nothing to do with the loss of hair in a woman 77 years of age. On the other hand, warfarin sodium may cause alopecia similar to that seen in alopecia areata. There is usually a regrowth of hair after the drug is withdrawn from therapy.

ASTHMA AND DOG DANDER

To the Editor:—*In augmentation to the question on asthma and dog dander, which appeared in* The Journal *for Aug. 9, 1958, page 1897, the breed of dogs known as Chihuahua are of a different origin from most other species. They are considered, by some, not to be dogs, inasmuch as they are descendant from the Mexican fox. Is it not possible, therefore, that an individual sensitive to dog dander may not necessarily be sensitive to fox dander?*

Forrest H. Howard, M.D.
12852 Palm St.
Garden Grove, Calif.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*Patients sensitive to dog dander have been tested with fox dander on a number of occasions. In all cases they reacted to the closely related fox dander. If the Chihuahua is a fox and not a dog, as the inquirer suggests, it still is likely that the patient would be allergic to it. That the Chihuahua furnishes comparatively little dander would be a more important factor than that it belongs to a different but closely related genus.*

HAZARDS OF USING PARENTAL BLOOD FOR MEASLES MODIFICATION

To the Editor:—*I have two comments concerning the Question and Answer on hazards of using parental blood for measles modification, which appeared in* The Journal *for July 12, 1958, page 1445. First, the inquiring physician asks about the hazard of using parental blood for measles modification "in case of an ill child." Once a person becomes ill with measles it is impossible to modify the disease by any means. On labels of commercial preparations of gamma globulin it is clearly stated that the material must be injected not later than the fifth day after exposure. Second, the answer to the question states that (after injection of whole blood into an* Rh*-negative girl) "an otherwise healthy young woman will never be able to have more than one child." In the classic example of a family afflicted with erythroblastosis, the first pregnancy is uneventful and the baby is normal. Then the second and all future pregnancies terminate in abortions, stillbirths, and infants with erythroblastosis. Presumably, the mother is sensitized during the first pregnancy or delivery. In the situation discussed in this question, the girl may be sensitized prior to her first pregnancy. In other words, a girl so sensitized may be able to have not even one child. Of all* Rh*-negative women producing* Rh*-positive babies, only 1 in 30 has difficulty with erythroblastosis. One theory for this is that the mother is sensitized only when there is mixing of the maternal and fetal blood, a pathological circumstance which occurs in the above proportion of cases. It would seem that the injection or transfusion of whole blood would sensitize a far higher proportion and be correspondingly dangerous. Far more women would be sensitized by an injection or transfusion of whole blood than would be sensitized by pregnancy.*

C. E. Berryhill, M.D.
Readlyn, Iowa.

The above comment was referred to the consultant who answered the original query, and his reply follows.—Ed.

To the Editor:—*These points made in the comment are well taken. The first statement is correct in that, if perchance the original inquiry was meant to refer to modification of measles in a child already ill with this disease, such a practice is not feasible or justifiable. Modification can only be successful if instituted prior to the onset of the disease, and the chances of success decrease rapidly beyond the sixth day after exposure. The second point is also worth stressing;* Rh *antibodies have been found in a high percentage of* Rh*-negative servicemen who had received transfusions. Hence, it is probably correct to state that the risk of sensitization is greater from transfusion than it is from pregnancy and that injection of whole blood during childhood could, in some cases, prevent a woman from having any children.*

CALCIFICATION OF THE ADRENALS

To the Editor:—*On page 1444 of* The Journal *for July 12, 1958, the question of calcification of the adrenals in a 3-year-old girl is raised. The consultant mentions that tuberculosis as a cause of adrenal cortical hypofunction in children is rare, yet he discusses the case from the viewpoint of this disease as based on tuberculosis. It is more likely that the x-ray findings indicating calcification in this child actually visualize bone tissue formation in the adrenal as the not uncommon consequence of adrenal hemorrhage. Adrenal hemorrhage is most often bilateral, although of different magnitude, whereas tuberculosis in a 3-year-old child, if present at all, would be most likely unilateral and too recent to lead to roentgenologically visible calcification. The distinction between metaplastic ossification and calcified tuberculosis is of clinical significance—the former is a stationary process, possibly ending in complete resorption, whereas the latter is likely to become progressive and sooner or later lead to adrenal cortical hypofunction.*

FLEMMING SCHEDULES HEALTH AND WELFARE CONFERENCES

Secretary Flemming of the Department of Health, Education, and Welfare has sent out invitations to some 400 heads of national organizations for a series of Washington meetings on subjects of mutual interest. He told one of his regular press conferences that the sessions were "in the interest of improving communications in the increasingly complex areas of health, education, and welfare."

The Secretary elaborated: "At these conferences the maximum possible opportunity is going to be given to the participants to present ideas to us. We will of course provide any factual information that may be requested relative to the operation of our various programs. But aside from this type of participation we plan to spend our time listening. Ideas presented to us will be taken under advisement and our reaction to these ideas will be made known at a later date."

So many groups are being invited to the conference on "health problems and emerging health needs," sponsored by the Public Health Service, that it has been decided to hold three separate but identical sessions. At this point, meetings are planned from Nov. 3 to Dec. 18. They are:

Nov. 3: Conference on vocational rehabilitation. This conference is being arranged by the department's Office of Vocational Rehabilitation.

Nov. 5: Conference on higher education. This conference is being arranged by the U. S. Office of Education.

Nov. 10: Conference on present status and future needs of mental hospitals in the country. This conference is being arranged by St. Elizabeth's Hospital and the Public Health Service's National Institute of Mental Health.

Nov. 26, Dec. 10, and Dec. 15: Three separate conferences with the same agenda on health problems and emerging health needs. These conferences are being arranged by PHS.

Dec. 1: Conference on primary and secondary education. This conference is being arranged by the U. S. Office of Education.

Dec. 11: Conference on health protection of the American people with particular concern for the manufacturing, storage, and distribution of food. This conference is being arranged by the Department's Food and Drug Administration.

Dec. 12: Conference on social security, public assistance, and child welfare. This conference is being arranged by the Social Security Administration.

Dec. 17: Conference on health protection of the American people with particular concern for the production, storage, and distribution of drugs. This conference is being arranged by the Food and Drug Administration.

Dec. 18: Conference on health and consumer protection. This conference is being arranged by FDA.

POLIOMYELITIS VACCINATION CAMPAIGN TO BE RESUMED BY HEW, AD COUNCIL

Disappointed over results of the poliomyelitis vaccination campaign, the Department of Health, Education, and Welfare is planning a revitalized program for this coming winter. Secretary Flemming has again asked the Advertising Council to help carry out the promotion, with the cooperation of the American Medical Association, the National Foundation, private groups, and state and local health departments.

The announcement was made along with release of a report on the poliomyelitis season just ending by Surgeon General Burney of the Public Health Service. Commented Mr. Flemming: "It is clear from this report that we have not made nearly the progress we could and should have made during the year—a year in which for the first time there was no shortage of vaccine at any time in any area."

Other points made by Mr. Flemming and Dr. Burney:

Fifty-three per cent of the population under 40 has not had the basic three inoculations and over a third has had no vaccine at all. There were 1,815 cases of paralytic poliomyelitis during the first nine months of this year, 258 more than in the same period last year.

A "very disturbing factor" is that in the six states—Michigan, New Jersey, Texas, West Virginia, Virginia, and California—that were most

(Continued on next page)

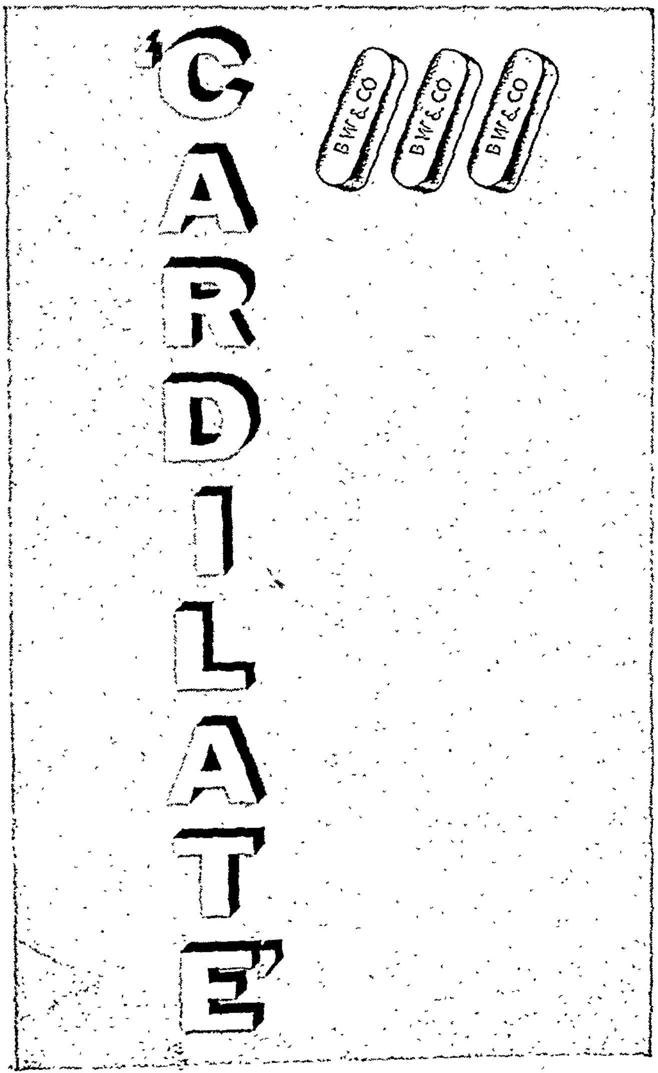
'CARDILATE' sublingual tablets for angina pectoris

"Nitroglycerin and erythrol tetranitrate when administered sublingually are among the most effective of all prophylactic agents available for the treatment of patients with angina pectoris. The comparatively prolonged duration of action of erythrol tetranitrate makes it especially valuable for clinical use."

Riseman, J. E. F., *et al.*: Circulation *17*:22, 1958

'Cardilate' brand Erythrol Tetranitrate
Sublingual Tablets 15 mg., scored.

BURROUGHS WELLCOME & CO. (U.S.A.) INC.
Tuckahoe, N. Y.



seriously affected the majority of paralytic cases, 416 out of 781, were among children under 5. Of these 416 children, four out of five had received no vaccine.

There is growing evidence that the incidence of polio is increasing in the lower income groups. Mr. Flemming blamed apathy rather than any "insurmountable financial obstacles." He said funds were available from a number of sources and that the A. M. A. has encouraged state and local societies to organize community clinics and provide vaccinations at minimal cost.

Dr. Burney's report stressed that the increase in the number of paralytic cases this year is no reflection upon the efficacy of the vaccine. During the three and a half years it has been in use the effectiveness rate of 60 to 90% has been consistently maintained. Nor is there any evidence that properly vaccinated persons are losing their immunity and becoming more susceptible to poliomyelitis.

The vaccine safety continues high, too, he said. The Communicable Disease Center reports no cases of poliomyelitis which could be traced to any lot of vaccine have occurred in over 200 million doses administered since May, 1955.

Both Mr. Flemming and Dr. Burney expressed opposition to any program of compulsory vaccination for poliomyelitis.

U. S. PHYSICIANS TOURING WEST GERMANY

Six American physicians, most of them active in medical research, have been invited by the German Foreign Office to be the guests of the government for a four-week tour of the federal republic. They leave New York early in November.

The tour is part of an exchange program with the U. S. inaugurated in 1952, with the objective of giving Americans an opportunity to become acquainted with present-day life and institutions in Germany. The German government also wishes to show its appreciation to the U. S. for opportunities given German citizens to visit this country.

The visiting team is made up of Drs. Robert C. Combs of San Francisco, Elmer Hess of Erie, Pa., former President of the American Medical Association and now chairman of the Health Resources Advisory Committee; Marga Hartmann-Sinclair, Anderson Hospital and Tumor Institute, Houston, Texas; Perry B. Hudson, Institute of Cancer Research, Columbia University, New York; Leslie A. Moren, Elko (Nev.) Clinic; and Hans Reese, Department of Neurology, University of Wisconsin.

After a welcome in Bonn, Germany, they will confer with representatives of the appropriate federal ministries and public health agencies, presenting their own problems and learning how similar problems are dealt with in Germany. They then visit various cities, including West Berlin, for talks with other officials and private doctors.

DRUG FIRMS ASK DROPPING OF FTC CHARGES ON ANTIBIOTICS

The six pharmaceutical firms cited in July on Federal Trade Commission charges they attempted to monopolize production and sale of tetracycline drugs have formally asked the agency to dismiss the complaint. They also deny the charge. The companies are Chas. Pfizer & Co., Inc., American

Cyanamid Co., Bristol-Myers Co., Bristol Laboratories Inc., Olin Mathieson Chemical Corp., and the Upjohn Company.

FTC singled out Pfizer as making misleading statements to the U. S. Patent Office in getting a patent in 1955 on tetracycline. FTC said Pfizer then issued licenses to the other respondents for various antibiotics.

Pfizer contended the FTC complaint covers alleged offenses outside FTC jurisdiction. American Cyanamid argued that a patent issued by the Patent Office is presumed to be valid. It added that licensing arrangements between the companies made it possible for them to compete vigorously in the sale of tetracycline.

PAMPHLET LISTS IMPORTANT RUSSIAN MEDICAL JOURNALS

"Guide to Russian Medical Literature," a 90-page booklet, has just been published by the National Library of Medicine, a part of U. S. Public Health Service. It lists 137 important Russian medical journals and reviews 20 others that have been translated into English and are available.

The pamphlet explains where Russian medical publications may be obtained and gives detailed information on available Russian bibliographical sources in special subject areas.

Articles in Russian and Bulgarian giving information about medical libraries, medical publications, and medical bibliography in the Soviet Union are translated in the guide book, which includes notations on Russian bibliographies available in the National Library of Medicine.

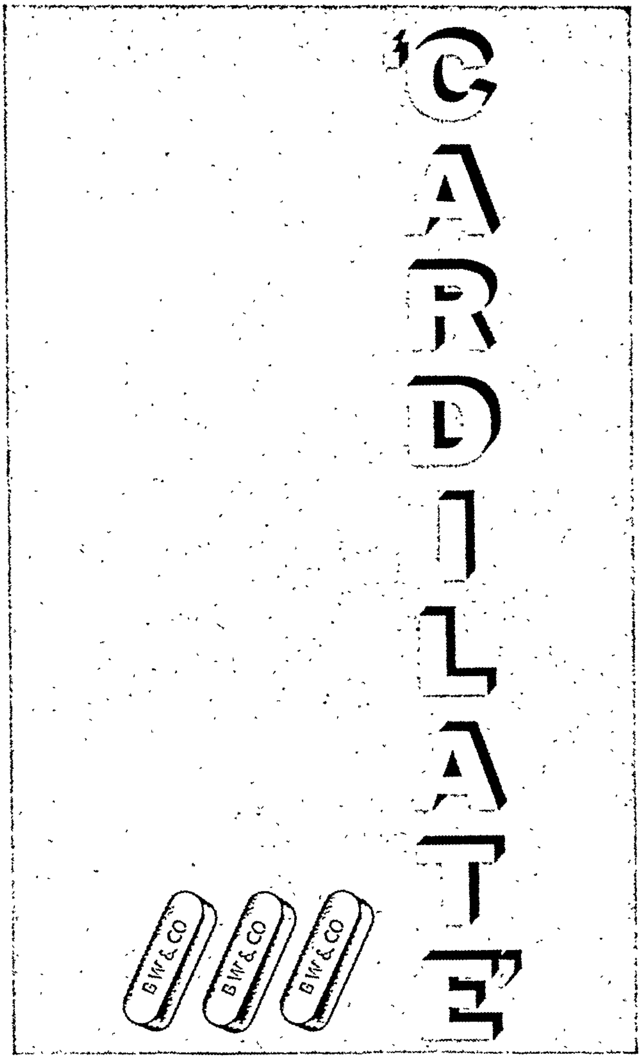
The book was edited by Scott Adams, librarian of the National Institutes of Health, and Dr. Frank B. Rogers, director of the National Library of Medicine. Copies are available from Superintendent of Documents, Government Printing Office, Washington, D. C., at 40 cents each. Ask for PHS pamphlet no. 602.

MISCELLANY

Food and Drug Administration estimates that during the fiscal year ending last July 1 food and drug firms made 141 individual plant improvements, costing over 11 million dollars, to aid in protecting health. FDA also reported that over 4 million pounds of unfit foods and $159,000 worth of unfit drugs were removed from market channels; this covers only actions observed by inspectors, and FDA said many other similar actions probably have been taken.

The Internal Revenue Service has ruled that tax-deductible medical care includes the entire cost of institutional care for a person who is mentally ill and unsafe when left alone. The case involved a mentally retarded child whose doctor felt that it was neither safe nor practical for him to remain with his parents or in an urban community. He was placed in a home with an opportunity of marginal adjustment.

Atomic Energy Commission has accepted 57 scientists, 50 of them from 18 foreign countries, for enrollment in the eighth session of the AEC International School of Nuclear Science at Argonne National Laboratory at Lemont, Ill., North Carolina State College, and Pennsylvania State University.



'CARDILATE'
sublingual tablets for angina pectoris

Sublingual administration obviates inactivation of nitrites in gastrointestinal tract.

Most closely approximates nitroglycerin in frequency and degree of effectiveness.

THE PREMARITAL EXAMINATION

Paul Scholten, M.D., San Francisco

The premarital examination required by law is sometimes cursory, sometimes thorough; in any case it brings the bride and groom to the physician. Although the gynecologist is uniquely fitted for premarital counseling, the general practitioner is at present the one most frequently consulted. The interview cannot follow a set pattern because of the diversity of situations encountered, and in some cases more than one interview is necessary. The premarital examination here outlined consists of laboratory studies, general evaluation of medical history and sexual knowledge, general physical examination, a pelvic examination, and a conseling session. Circumstances do not always permit immediate answers to all questions, but many informative books are now available. From the list here given, the physician should choose some that most nearly represent his own convictions, so that he can recommend them in such cases. To a physician who is sufficiently interested and has adequate time and training, the premarital examination is an opportunity to help substantially to preserve the American family life.

DUE TO THE almost universal adoption of compulsory premarital health examination laws by the various states, the premarital blood test has become an accepted part of preparation for marriage in America today. Starting with Connecticut in 1935, to date 46 of the states have passed such laws. These statutes are primarily measures for the control of infectious venereal disease and, in most instances, require a serologic test only. However, some of the states require an additional physical examination, aimed at detecting primary syphilitic lesions, even though the disease has not yet progressed to a point evidenced by a positive blood test.

These premarital examination laws bring the bride and groom to the doctor. Once there, the premarital examination they receive can be purely cursory and consist simply of the blood test or it can consist of a complete medical examination in the full sense of the term. It is such an examination that is herein outlined, for, while the premarital examination is usually initiated only to fulfill legal requirements, it also offers the physician an opportunity to be of genuine service to the patient and to the community.

An increasing number of marriages are ending in divorce. Statistics show that one of four marriages will not survive for five years. In some localities this figure may rise as high as one out of three. In addition to those couples who actually get to the divorce courts, there must be a reasonable per-

Read before the Section on Obstetrics and Gynecology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

centage of unhappy marriages that are never resolved in an attorney's office. While not all divorces or unhappy marriages arise from a sexual basis, a surprisingly high percentage do have their origin in some disagreement at that level. Although we can only surmise as to how many cases of incompatibility and mental cruelty fall within our field, we as physicians can help to cut down the number of unsuccessful marriages by giving more attention to counseling before marriage in the hope of eliminating some of the frustrations and points of conflict before they arise.

Not all couples who are happy in the most intimate act of marriage are compatible in other interests, but it is certainly safe to state that those who are unhappy in their sexual relations are usually unhappy with most other aspects of their marriage as well. On a medical level, we can only estimate how much marital strife shows up in a doctor's office as pelvic pain syndromes, menorrhagia, dyspareunia, fear of pregnancy, and other similar psychosomatic disorders. Certainly, many of these complaints could be prevented or minimized by adequate premarital counseling. Such counseling is a specialized field for which the physician, and in particular the gynecologist, is logically fitted by his background and training.

At present a number of organized groups offer short courses and conferences in family relations for the newlyweds or the about-to-be-married; these include various church denominations, the Y. M. C. A., educational institutions, and planned parenthood foundations. In addition, many of our colleges and universities now give family relation or marriage courses to the undergraduate students. All of these agencies, while doing good work, tend to be impersonal, generalized in subject matter, and unavailable to the vast majority of the population at the particular time when they are most needed—the immediate prenuptial period.

On the other hand, the physician should be the logical man to carry out such counseling since he is readily available, should be fully understanding, and is specifically trained for the job. By virtue of his specialty, the gynecologist is uniquely fitted for premarital counseling and increasing numbers of prospective brides are now coming first to gynecologists for examination. At present, however, most premarital examinations are done by the general practitioner, and this may be appropriate inasmuch as he examines both prospective bride and groom and can correlate their individual problems. He is frequently already one or the other's family doctor and has established the good rapport needed for intimate advice. But it is important that a proper gynecologic approach to the problem be used too and that adequate premarital counseling be done at the time of premarital examination. Occasionally the psychiatrist should become a part of the counseling team but usually only when he is called in consultation because of some major, deep-seated emotional problem related to the marriage.

Premarital counseling should be preventive medicine, aimed at warding off causes of future disagreement by means of advice, instruction, and education. As Pearson [1] has pointed out, it differs from marriage counseling, which aims at patching up a marriage already in danger of break-up and which requires specialized legal and psychiatric knowledge. Premarital counseling needs only basic gynecologic training, plus interest and adequate time on the part of the doctor.

When the prospective bride does come to the doctor, how is he to manage the consultation? It has been suggested that the best counseling relationship be an informal one and that no set pattern be followed but rather that the patient be allowed to ask questions and to direct the counseling toward the subjects she desires. Unfortunately, this would be time consuming and, with a nervous or frightened patient, the essential subjects may never be covered. Preferable is the use of a basic outline for an adequate premarital examination so that essentials can be covered in logical sequence.

Easley [2] suggests that the premarital examination should involve three office visits. A brief preliminary visit is made which is confined to generalizations and nonmedical subjects in order to put the patients at ease and to set the stage. At this time the blood test is taken or ordered but no actual examination is done. On the second visit the physical and pelvic examinations are done, but it is not until the third visit that conclusions and advice are given and the prospective husbands seen. If the consulting physician does not treat males, he may refer them for general history, physical examination, and serology and then later counsel with them as indicated.

This plan presupposes that the premarital advice will be sought at an ideal time four to six weeks before the wedding, but, unfortunately, most couples wait until the last moment or at least the last week before initiating the medical examination. Although most gynecologists are pressed for time, certainly with a basic plan in mind they can do a praiseworthy job in a single consultation of about 25 to 30 minutes. To help to accomplish this, I would like to suggest an outline of an adequate premarital examination consisting of (1) laboratory studies, including the required serologic test for syphilis, (2) general medical history and sexual-knowledge evaluation, (3) a thorough physical examination, (4) a pelvic examination, and (5) advice and counsel.

Outline for Examination

Laboratory Studies.—The serologic test for syphilis is mandatory and usually is the only laboratory work demanded; however, additional laboratory tests that are often used to complete a premarital medical survey include Rh factor determination, hemogram, urinalysis, and a chest film.

History.—A brief general medical history should be taken. Most of the premarital patients seen will be in a young, generally healthy age group, but the usual review of past illnesses, accidents, operations, systemic and familial illnesses, and anomalies is important. Menstrual history should be carefully elicited and patterns established. The last menstrual period may be important in regard to the actual date set for the wedding. Menstrual physiology may be reviewed as an aid to judging the woman's knowledge of her bodily functions. This logically leads to an evaluation of her sexual knowledge and experience. This evaluation can be casual and brief, consisting of a few simple questions, or it can be quite formal and detailed.

About 50 to 60% of women seen in premarital consultation will be virgins and a number more will be near-virgins with limited sexual experience. One should ascertain past sexual activities and, even with the virgin, discreetly question about prior attempted sexual contacts and possible traumatic experiences. Of note at this point are the 10 to 25% of brides who will already be pregnant at the time of marriage. Your whole scheme of advice will have to be changed by this. It is wise for preserving your own composure and that of the patient if you refrain from detailed advice about first intercourse and the wedding night until you find out if she is pregnant.

Most women in this day and age will have some knowledge of sex, even if they have had no actual experience. Some will have been previously married, widowed, or divorced, and a history of this should be obtained. Almost all will have read one of the many available books on sex and marriage by the time you are consulted. Many, however, will not have absorbed very much from their reading; some will have absorbed only misconceptions; and some will remain completely ignorant of what the marital act actually involves. Preliminary questioning at this point serves to bring this out and to establish a basis for advice to be given later.

For a more detailed, formal evaluation, several excellent interviewing aids devised by Dr. Gelolo McHugh of the department of psychology of Duke University are available from the Family Life Publications, Inc., of Durham, N. C. These are the "Sex Knowledge Inventories," form X and form Y, questionnaires that the patient fills out before the interview. Form X is an objective measure of sex knowledge through 80 multiple-choice questions covering the whole field involved in marriage counseling. Form Y measures individual understanding of sex vocabulary and anatomy through labeled diagrams and matching-type questions. These forms can be used independently or together. They are a counseling tool which may be helpful in saving time and in giving a basis for discussion by pointing out the areas of knowledge where counseling is most needed. Their successful use depends more on the counselor than on the tests.

Whether by formal questionnaire or informal discourse, some sort of sexual history should be taken if the physician is able to elicit it. He should also question about parental marital life and parental attitudes toward marriage, children, and sex. The child is the mirror of the parents and thus many families perpetuate mistakes and unhealthy attitudes from generation to generation.

Physical Examination.—After the maximum knowledge is gained from the history, a complete general physical examination should be done to rule out general or systemic disease.

Pelvic Examination.—The pelvic examination is essential, with especial attention paid to hymenal presence, dilation or dilatability, discharges, cervicitis, polyps, Trichomonas or Candida (Monilia) infections, pelvic anomalies, developmental defects, possible senile changes, childbirth injuries, or any other variations from the normal.

Kavinoky[3] suggests that, at this point, when examining a girl of no or little experience, the insertion of a plain laboratory size Pyrex test tube, well lubricated, will help the patient to realize that there is a normal opening in the hymen and that it leads to a normal deep vaginal canal. This will demonstrate better than words can the normal vaginal axis and capacity. If a contraceptive device is to be fitted, it should be done at this time.

Occasionally at the time of pelvic examination, we will find a thick, rigid, or imperforate hymen. We can help this condition by office dilation or, rarely, surgical hymenotomy or hymenectomy, but the latter should be reserved for only the most serious cases. Much worse for the bride than a tight hymen is a tender area of healing for three to six weeks after surgery.

If the patient has several weeks remaining until the wedding, it is best to accomplish dilation in the office with the gradual use of a well-lubricated set of graduated dilators. If she has only a minor degree of tight or thick hymen, advice may be given on how to use adequate water soluble lubricants or one of the less sensitizing anesthetic lotions to help her ease the initial discomfort of intercourse. This anesthetic lotion, at the same time, may be valuable in controlling premature ejaculation in the male. Usually, nature is the best dilator and should be given a fair trial. In some cases, Kegel exercises, used over a period of several weeks to months, may be of aid in securing relaxation.

After the physical examination, the patient is told to dress and is then seen in the consultation room for the actual counseling and advice. Any findings or details of technique for intercourse should not be discussed while the patient is still on the table.

Advice and Counseling

By choice, the counseling should be fairly extensive. If for any reason it must be minimal, allow at least a short time for answering specific questions that have arisen, and then, certainly, direct the patient to adequate available literature for sources of more complete answers.

For the busy physician there are a number of source materials available in the form of pamphlets or books which may be dispensed or recommended to the patient. Several of the pharmaceutical companies put out booklets giving a small amount of advice on marital hygiene and sex, but these booklets are mostly inadequate and often are only thinly disguised advertisements. A more adequate and more to be recommended pamphlet is a reprint of a very popular editorial from the journal, *Obstetrics and Gynecology* (4:355-360 [Sept.] 1954) titled, "A Young Woman Seeks Premarriage Counsel" by Dr. C. O. McCormick. This is a well written article in first person style which has gone into many printings and which may be purchased at a nominal price from Paul B. Hoeber, Inc.

There are a number of other pocket-sized manuals on sex and marital guides, each 75 to 100 pages in length, which are available to the physician for 60 to 75 cents a copy if purchased in bulk. These have been written with the intention that the doctor should dispense them at the time of the premarital examination. These manuals contain information on basic anatomy, physiology, sexual technique, and contraception. They serve to round out the physician's advice but each booklet contains some controversial information, and the individual physician would do well to read them carefully before recommending them in order to make sure that the contained information coincides with his own ideas. These pocket-sized books include "Sex Without Fear" by S. A. Lewin and John Gilmore, "A Doctor's Marital Guide" by Bernard Greenblat, and "Sex Manual" by G. Lombard Kelly.

Other more formal volumes which may be recommended for further study include "A Marriage Manual," Hannah and Abraham Stone, "Modern Pattern for Marriage," Walter Stokes, "When You Marry," Evelyn Duvall and Reuben Hill, "Successful Marriage," Morris Fishbein and Ernest W. Burgess, "Facts of Life and Love," Evelyn Duvall, "Sex Factors in Marriage," Helena Wright, "Before You Marry," Sylvanus Duvall, "Marriage Is What You Make It," Paul Popenoe, "Marriage for Moderns," Henry Bowman, "Marriage and Sexual Harmony," Olive Butterfield, "Building a Successful Marriage," J. T. Landis and M. G. Landis, "A Handbook for Husbands and Wives," Theodore Arden, "Family Living," Evelyn Duvall, "Personal Adjustment, Marriage and Family Living," J. T. Landis and M. G. Landis, "Marriage and Family Relationship," Robert Foster, and "Marriage," Robert Harper.

What are the usual questions a young woman wants answered when she comes for premarital advice? These usually include such topics as (1) whether she is generally healthy and physically able to bear children; (2) facts regarding family planning, regulation of fertility and conception; (3) detailed sexual information regarding techniques and hygiene and a chance to ask specific questions about these; and (4) legal requirements.

The physical and pelvic examinations certainly should enable the physician to reassure the patient about her physical well-being and probable fertility. Family planning or regulation of fertility is one of the larger elements in the premarital counseling and often is the reason for selecting a gynecologist. Very few couples, given the choice, desire a pregnancy immediately after marriage. Generally speaking, it is better if there can be a short period before pregnancy ensues, in which time the couple can make the necessary adjustments to sex relationships, finances, and other aspects of marriage. It is often hard for two young people to adjust to each other under ordinary circumstances, but it is much more difficult when one of them is suffering from morning nausea, malaise, and the increased irritability that may come with pregnancy.

However, it is advisable for the doctor to caution against waiting too long to have children, especially the older age groups. Too often couples postpone pregnancy year after year for reasons of finances, education, and housing, only to find they have an infertility problem when they do attempt conception. In general, contraception, by whatever method, should not be prolonged for more than two years at most. Advise, too, that failure of conception, when attempted, calls for prompt medical consultation and corrective study as soon as possible, preferably within 6 to 12 months.

Detailed methods of contraception are too well known to devote space to them here. The physician must always keep in mind the couple's religious and ethical beliefs, and it is not for him to lay down any standard of conduct. He must merely advise and counsel. The amount of counseling the physician may give couples depends to a considerable extent on their own needs and questions. Scheffey[4] has noted that some couples are healthy and emotionally mature individuals, looking forward to the joys and companionship of marriage. Others have physical problems; while still others are normal physically but unstable and underdeveloped emotionally. The amount of counseling also depends on the physician's own maturity and interest and how well he can convey an interesting and intimate body of advice.

Specific Points of Advice

Libido.—It should be pointed out that while both sexes are equally capable of enjoying the sex act, the libido differs from men to women. Men are usually ready for sex with minimal stimulation, while women are usually less interested in sex as such, taking a more natural or matter-of-fact attitude. Hollywood, television, modern magazines, and novels have all led men to glamorize sex. Women can enjoy sex as much as men do, but they are usually not aroused as quickly nor as easily. Many times women wonder what men get so excited about. While a man may become aroused at the sight of a tight sweater, the same is certainly not true of most women. As a general rule, the average woman is less interested in sex and will be satisfied with sex about half as often as her spouse is. This is especially true if she has small children and the labors of a busy household. Of course, this is less likely in the early months of marriage when the young couple is free to devote all of their time to pleasing each other.

Frequency of Intercourse.—Questions concerning frequency of intercourse are commonly asked. We as physicians must once again be careful about laying down any specific rules or limitations. We can advise that there is no set pattern for the first six months or so because that is a time of trial, experiment, and mutual adjustment. We can say that after this approximate length of time, most couples settle down to a pattern of intercourse about twice a week, occasionally three to four times a week, but that this is only an average estimate and the number is an individual matter of mutual demand, agreement, and satisfaction.

Orgasm.—The orgasm or climax is a mysterious subject to most prospective brides. While about half will have had some prior sexual experience, the majority will not have experienced orgasm. Most, however, will have read of the orgasm and found it described as vital to sexual and marital happiness. Most authors have difficulty in explaining what orgasm actually is; and it is indeed hard to describe such a vivid but almost entirely emotional experience. If the girl is a follower of Hollywood, true confession magazines, or Hemingway, she may well expect orgasm to be accompanied by a flash of lightning, a roll of thunder, and a small earthquake. If so, she will most certainly be disappointed and may not even recognize the event when it does happen.

The difference in a man's orgasm and a woman's orgasm can best be explained by saying that in the male there is an actual emission which gives a definite end or climax to the act; in a woman, however, orgasm is merely a lessening of tension after a building up of warmth, emotion, expectancy. This comes as a sudden release with an accompanying feeling of pleasure, warmth, love, togetherness, and relaxation. Orgasm in both can be likened to a sneeze in which there is a building up of tension and of expectancy and then of release. The physiological points of increased pulse, increased blood pressure, more rapid respiration, and then the slowing down of all these may be pointed out. But perhaps in the end we must agree with a local doctor who counsels, "If you have to ask what an orgasm is, you haven't had one; if you do experience orgasm, you won't have to ask." We can also explain that after intercourse and orgasm, the couple is usually relaxed, happy, and ready for sleep.

Further explain that the normal man will experience orgasm each time he has intercourse, but in general a woman will achieve it only about half as often. This latter fact is due to several factors: 1. The woman is generally more slowly aroused and if the husband is hasty, clumsy, inattentive, or inexperienced, he may be finished before the wife is more than mildly interested in what is happening. 2. Orgasm requires both relaxation and concentration on the part of the woman. If she is tired, nervous, or afraid of pregnancy, still upset from a busy day or family life, she may not be able to relax. If privacy is lacking, as it is with couples living with in-laws, or who have children in the same room or nearby, or have neighbors or television or radio in the next room or flat, concentration is practically impossible and a successful climax is usually denied. It may take many months after the honeymoon for a woman to acquire enough relaxation and concentration to achieve orgasm. If this is not explained to the bride-to-be in advance, initial experiences may lead her to frustration rather than to enjoyment.

It is ideal if both parties reach orgasm at the same time, but this is only the ideal and is neither essential nor usual. As stated, the wife usually experiences a climax only about half as often as her spouse does. Occasionally a woman will be more easily aroused, but, on the other end of the scale, perhaps 10% of women will never experience an orgasm throughout their married lives. We can warn the prospective bride of this but should hasten to add that, even without orgasm, a marriage relationship can be a beautiful and successful one. The sex act can still be a pleasure, a sharing of intimacy, a pleasurable warmth, and a joy in making a loved one happy. While there may be no abrupt climax, there can be an enjoyable building up of tension and a gradual release from it. Closeness can give satisfaction even without orgasm and we should give reassurance about this.

Actual techniques of intercourse may be touched on without undue emphasis. Point out that there are only four basic positions. While some of the more sensational guide books point out innumerable attitudes, in reality all are only minor variations of these basic four. None of these are either more normal or more abnormal than others; nor should variations in sex technique be a cause of embarrassment to either of the newlyweds. The first few months of the marriage are ones of experimentation and trial in all fields of mutual living and sex is no exception. It is important to point out here that there is no absolute line of normality or abnormality in regard to the sex act. Anything that gives mutual satisfaction to both parties is normal. That which one party finds unnatural or unpleasant or disgusting or abnormal, is abnormal.

Frigidity.—Frigidity is a special problem but usually is not part of the premarital consultation save as a fear on the part of the bride. This fear usually implies prior unhappy experience. Most frigidity is on a purely emotional level and is very rarely physical. All we can do is to sincerely reassure the patient that there is no physical bar to successful intercourse and to emphasize the fact that within a few months time marital adjustment will usually provide the relaxation and relief of tension needed to solve the problem. Some mild cases of fancied frigidity will be aided by small doses of testosterone over a six-week period. This therapy seems to help emotionally and it will certainly cause some clitoral hypertrophy. True frigidity, however, is primarily a problem calling for psychiatric assistance. Of course if there is a physical bar to successful coitus, such as a rigid hymen or a tender introitus, we can and should offer therapy.

It is most important that the wife be able to discuss sex frankly with her husband if they are to achieve mutual satisfaction and success in marriage. She should never simulate orgasm just to please her husband since honesty is vitally important in this most intimate aspect of marriage.

We can suggest that occasionally the wife should initiate the sex act. This is flattering to the man and strengthens his opinion of his own value and desirability. Conversely, she should refuse only rarely to have intercourse, since in this she is rejecting that which her spouse considers the most valuable and personal thing he has to offer her. She should not be ashamed of sex. Intercourse is not intended solely for pregnancy but for pleasure as well. For a successful marriage, a woman must be many things to her spouse—a good cook, a housekeeper, a mother to her husband, and a good mistress as well.

General Points of Information

We should try to correct certain implied psychological threats by pointing out that it is not true that the hymen must break painfully and bleed to prove virginity; that it is not true that compatibility is proved by simultaneous orgasm; that this is ideal, but unlikely; that the husband is not directly responsible for the wife's orgasm, although the friction does cause the stimulus initiating orgasm; that orgasm is more a mental and an emotional reaction than a physical one on the bride's part.

There are certain personal matters that should be touched on. Most newlyweds will be living in small apartments and of necessity be thrown into very constant intimate contact. In such a close atmosphere, it is important that they keep their bodily functions personal; for example, they should keep the bathroom door closed when so occupied and in turn respect each other's privacy. Sanitary napkins and belts and douche bags are best kept under cover. The bride should be advised against lounging around in an old dressing gown or in her underwear. Occasionally the half-dressed form is an exciting thing to see, but in general nudity removes the mystery and cheapens and coarsens the interpersonal relationships. Daintiness in a woman is still a virtue and an intensely attractive aspect.

Douching might be mentioned at this point. Most girls about to be married will not have had occasion previously to use a douche. Explain that a routine douche is not necessary, but an occasional postcoital or postmenstrual douche may be desirable. For this purpose a simple vinegar and water douche should be sufficient, and it would be wise to explain how to douche in the bathtub or on the toilet.

We should give the patient an opportunity to ask specific questions which our counseling has raised or has left out. We can point out that the physician is usually a better source of premarital advice than are well-meaning friends.

Now arises the problem of the pregnant bride. This is a common one, since approximately 10% of all women are pregnant when wed. Kinsey[5] and others raise this percentage to as high as 20 and 25%. Under these circumstances, reassurance is the most important therapy we have to offer. Telling the girl that her plight is not an uncommon one is a valuable adjunct. It can be more comforting to her if you point out how rare it is that anyone ever makes an untoward remark to the mother of an 8-lb. "premature." Naturally, anyone who can count will be able to figure out what has happened but, in general, friends and relatives will prove to be surprisingly compassionate in this regard. It is sometimes wise to reassure the girl that she has done the right thing to decide to be wed, once she has made her own decision. It is equally important that the doctor not make the decision for the patient. Instead, he can point out the various courses open, and there will be numerous cases where placing the infant for adoption may be far preferable to a shotgun wedding.

The divorcee or the widow who is about to be remarried will usually know the basic facts about sex and obviate the need for a formal lecture or list of details. However, it is just as important that she be given a chance to ask any questions she desires answered, since prior marriage is no proof of adequate ability to adjust to marriage.

Marriage in later life poses several problems. While pregnancy is less likely to occur, if it does, it is also more prone to bring complications. After the menopause there is an actual shrinkage of tissues, loss of elasticity, and loss of lubricating secretions. Advise gentleness of techniques in intercourse in order to avoid tearing of tissue and advise the use of lubricants, of which the water soluble ones are best. For some patients, local or generalized estrogenic substances are advisable and, in some cases, the anesthetic lotions or ointments may be helpful.

One final word may be said about preparing for the actual wedding and the honeymoon. Modern marriage is more conservative than some would have us think; it still retains much of the ritual and mysticism of our primitive ancestors. What with showers, fittings, rehearsals, bachelor parties, the ceremony and the reception, a wedding can become an almost barbaric rite. By the end of the usual ordeal, the bride and groom may both be in a state of near-collapse, both mentally and physically. The treatment must be individualized to the patient, but quite often a course of one of the simpler tranquilizers during the last prenuptial week will serve to help retain the bride's sanity. Meals usually become highly irregular, so a mild laxative nightly can also be helpful during these last few days before the wedding. A conscious effort on the part of the bride to force fluids will do much to help her cut down on honeymoon cystitis. Point out that it is not necessary to consummate marriage on the wedding night; often it is much better to wait until both parties are sober, rested, and relaxed.

Menstrual physiology can be touched on briefly or outlined as indicated by the evaluation made earlier or answers received when making the initial sex-knowledge inventory. Many young women are dismally unaware of their bodily functions and certainly those patients who refer to menstruation as the "curse" could stand a little missionary work. An outline of menstrual physiology forms part of the family-planning counseling and should be the basis for use of the so-called rhythm system or of the safe period.

If you are able to attain good rapport and assume a properly fatherly attitude toward the patient, there are a number of subjects that can be added as a part of the individual's technique of counseling, depending on how well the physician fits the role. Some of these subjects, while not an essential part of the counseling, can form an effective part of it if properly conveyed to the patient. Little things can be mentioned that tend to keep the romance of marriage alive and flourishing, such as remembering anniversaries, the parting morning kiss, avoiding quarrels, avoiding criticism of the spouse, making a 50-50 partnership of the marriage. Financial security and budgeting may be touched on. Religion should be discussed as a fundamental aspect of the family and the marriage and how the church should enter into the life of the new family. The imparting of these subjects is dependent on the counselor's gray hair and ability since they are interesting but not essential.

What is essential is the proper gynecologic approach and adequate counseling at the time of the premarital examination. The physician can help to preserve the American family life by premarital and marital counseling, by advice on child spacing and family planning, by good obstetric and gynecologic care. The ideal physician for this task should have personal warmth and sympathetic understanding, but basically he need have only interest, adequate time, and adequate training.

SOLAR CARCINOGENESIS.—Collagen degeneration of the skin arises in persons with inadequate cutaneous pigment from excessive exposure to solar radiation. By altering the nutrition of the epidermis, collagen degeneration predisposes to the development of solar keratoses, keratoacanthoma, squamous-cell carcinoma, and basal-cell carcinoma; when present in only moderate degrees it can intensify and accelerate other carcinogenic influences. Our final conclusion is that the carcinogenic effect of ultraviolet light is mediated by its primary action on the dermis. —B. S. Mackie, M.B., B.S., D.D.M., and V. J. SUBTOTAL CYSTECTOMY AND TOTAL BLADDER REGENERATION IN TREATMENT OF BLADDER CANCER

Roger Baker, M. D., Timothy Kelly, M. D., Timothy Tehan, M. D., Charles Putnam, M. D.
and
Edouard Beaugard, M. D., Washington, D. C.

Three types of operation are particularly important in the treatment of cancer of the urinary bladder: transurethral resection, suprapubic segmental resection (which may be subtotal), and cystectomy. Considering the difficulty of complete extirpation of the lesion by transurethral route and the disadvantages of cystectomy to the patient, the authors are convinced that the former is too likely to prove inadequate and the latter unnecessary and too radical. In their experience nearly all of the bladder can be removed by the technique of suprapubic segmental resection without depriving the patient of the possibility of ultimately regaining good vesical function. The operative mortality is not greater in proportion to the amount of bladder wall removed, for the remaining portion has the ability to regenerate all the layers of the normal bladder. Such regeneration occurred in all patients, and bladder capacities up to 410 cc. were attained. The subtotal operation is preferred even in patients with cancer so far advanced that the operation must be regarded simply as palliative, for it removes a mass that is a source of pain and hemorrhage.

In 1953 one of us first reported the favorable results associated with subtotal cystectomy and bladder regeneration in treatment of 16 patients with bladder cancer.[1] This paper presents data collected from five years of additional experience with the procedure in treatment of bladder cancer of all stages and grades. Subtotal cystectomy should be evaluated from two aspects: first, rationale for use of this type of surgery, and, second, clinical data concerning bladder regeneration. These will be handled separately.

Rationale for Use of Subtotal Cystectomy

The three surgical methods used practically to the exclusion of all others in treatment of bladder cancer are transurethral resection, suprapubic segmental resection, and cystectomy. Essentially subtotal cystectomy is a large or radical segmental resection. In order to justify the use of a radical segmental resection, the present cure rate associated with standard segmental resection for superficial infiltrative or deep infiltrative bladder lesions should be equal to or better than that obtained by transurethral resection or total cystectomy.

Transurethral Resection.—Critical appraisal of transurethral resection as a therapeutic modality for superficial or deep infiltrated vesical cancers indicates that it falls short of the usually acceptable surgical techniques employed in treatment of malignancy. First, the operator is restricted in the extent of his resection by the possibility of perforating the bladder wall. For even small or superficial infiltrative bladder cancers the operator must not resect more than about 0.3 cm. beneath the tumor or he will cut a hole in the inflated bladder and have extravasation of the irrigating fluid into the retroperitoneal or intraperitoneal space.

This obligatory restriction of even local excision of a malignant tumor should be condemned. The fact that the cure rate of superficial infiltrating vesical cancers treated by the transurethral method is good should not deter the urologist from improving on these statistics. When a particular cancer in a particular patient is viewed through the resectoscope, the urologist is unable to determine whether that particular tumor will fall into the statistical group that can be treated successfully by transurethral resection. Due to this inability of prediction of depth of infiltration and circumferential spread of the cells within the bladder wall, each patient should be given the benefit of at least having the entire thickness of the bladder wall beneath the neoplasm excised with the tumor en bloc. This cannot be done by transurethral resection.

In previous reports, we have clearly demonstrated that certain bladder cancers of even a superficial nature can spread a considerable distance away from the lesion within the bladder wall and that this spread is not visible through the resectoscope.[3] Moreover, this spread of cancer cells within the bladder wall cannot be palpated at the time of exploration of the bladder via the suprapubic route. It was demonstrated that in certain cases considerably more than a cuff of "normal" bladder around the tumor must be excised to remove all cancer within the wall of the bladder. More recently we have observed that, even with superficial infiltrative lesions, tumor cells can be found in the adventitia or fat immediately adjacent to the bladder. It is

Read before the Section on Urology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

impossible to remove these cells by the transurethral resection method. In addition, as it is not possible to predict at the time of suprapubic segmental resection which patient requires a larger or smaller segmental resection, each patient should be given the benefit of the larger resection with full realization that the smaller resection would have cured a large number of the superficial infiltrating carcinomas. This approach is logical and valid provided the operative mortality of the larger segmental resection is no greater than that associated with the smaller segmental resection or the transurethral resection. In our studies and those of others with comparable but smaller series, the operative mortality is no greater.

From a statistical standpoint a review of the more recent significant results associated with treatment of superficial infiltrating carcinomas of the bladder by electro-excision demonstrates a five-year survival rate of about 67%.[3] Persons with tumors of similar stage and grade treated by segmental resection have a similar (66.3%) five-year survival rate.[4]

At this point another misconception should be corrected concerning this method of therapy. It has been stated that the reason transurethral electroexcision fails to cure some patients with superficial infiltrating carcinomas is that the tumors are multifocal in origin. This is usually not true. In actual practice most urologists use segmental resection for two types of patients: those initially seen with large lesions and those where previous transurethral resection has failed to cure and some more "radical" procedure must be used. The fact that the cure rate with segmental resection is so high indicates that the "multifocal cause of failure" attributable to the transurethral electro-excision method is not valid in most patients. One thing can be stated. If transurethral electroexcision is used in treatment of even superficial infiltrating bladder cancers, about 30% of these patients will die of their disease.

There is much evidence to indicate that the statistics associated with segmental resection are actually considerably higher than the mean of 66.3% reported in the more significant papers published to date. As stated above, most urologists do not utilize segmental resection for the smaller lesions. The procedure is reserved for the larger lesions which can be expected to have a poorer survival rate than smaller lesions. Again, most urologists do not utlize segmental resection in the initial treatment of these lesions. Thus, it is seen that many of the patients in the 66.3% survival rate group have previously had transurethral resection which has failed to cure the patient. The carcinoma at time of segmental resection, therefore, is one which has existed within the patient for a longer period of time. Such patients can be predicted to have a lower survival rate than those initially treated by the method. Disregarding these considerations, it can still be stated that segmental resection is equally as effective as transurethral resection for even superficial infiltrating carcinomas of the bladder. Based on all of the considerations mentioned, it is reasonable that if all of these superficial infiltrating carcinomas were treated by a larger segmental resection the present survival rate with the procedure could be increased.

Deep infiltrating carcinomas of the bladder treated by electroexcision have a five-year survival rate in the range of 12%.[3] When this same type of infiltrating carcinoma is treated by segmental resection, the published mean five-year survival rate is approximately 15.1%.[4] This last figure may be slightly higher than that which can be obtained in treatment of unselected cases with standard type of segmental resection. In any case, the statistics published to date indicate that segmental resection is at least as good, if not better, treatment than transurethral electroexcision for deep infiltrating carcinomas of the bladder.

Cystectomy.—Only a few urologists routinely perform total cystectomy for bladder cancer. Most urologists do not support the stand which states that cystectomy is absolutely necessary to effect cure of this disease. Some contend that if cystectomy is curative then a less radical procedure would also have cured the patient. Many firmly believe that the operative mortality associated with cystectomy cancels out the increased five-year survival rate that might be obtained with the procedure. Many urologists contend that the renal complications associated with cystectomy and transplantation of the ureters to the skin or functioning rectosigmoid, defunctionalized rectosigmoid, or ileal loop do not justify use of the procedure. If the cancer cure rate were sufficiently high after cystectomy and ureteral transplantation, the justification for making a significant percentage of these individuals "renal invalids" would be present. Moreover, these patients usually have some type of external collection apparatus for either urine or feces which certainly tends to make these individuals a type of urologic cripple, it not renal cripple.

Anyone practicing urology at an active university hospital where many postcystectomy referral patients are seen can attest that there is in fact much justification for these concepts concerning cystectomy and the results of diversion of the ureters. As a consequence it is not totally unreasonable that most urologists treat these patients with transurethral or segmental bladder resection. Complete pessimism concerning cystectomy is not reasonable, however, for recently the procedure has been generally used as a "last ditch" procedure for advanced bladder cancer. In the majority of the published reports, cystectomy was resorted to only after more conservative types of treatment had failed. As such, these patients must also be classified as failures for the conservative management. This is seldom specified in published reports. Since most urologists perform relatively few of these operations, the incidence of operative mortality and complications of all types, including the renal variant, are greater than those of the few urologists who have much experience with the procedure. Actually, use of the ileal pouch for diversion of the urinary stream has fewer renal complications than formerly experienced with other types of ureteral transplantation. For those who have not performed the procedure, however, it should be remembered that the ileal pouch technique is a major operation in itself. The delayed renal complications usually associated with other methods of diversion of the urinary stream are lessened but not eliminated with the ileal pouch technique.

The present indications for total cystectomy have not been definitively established. Of more importance is that the necessity for cystectomy, as compared to segmental resection to effect cure, has not been proved. There are apparently only two exceptions to this stand, namely, multifocal vesical cancer and infiltrative lesions immediately at the vesical neck. Both require cystectomy. Superficial infiltrating carcinomas of the bladder treated by cystectomy have a mean five-year survival rate of 43.3%.[5] Lesions of this same group treated by segmental resection have a mean five-year survival rate of 66.3%,[4] indicating that segmental resection may well be a better surgical method of treatment than cystectomy for these superficial infiltrating lesions. Deep infiltrating cancers treated by cystectomy have a mean five-year survival rate of 9.9%.[5] This same type of lesion treated by segmental resection has the higher five-year survival rate of 15.1%.[4] Cystectomy is usually selected for the larger lesions. Such tumors can be predicted to have a lower survival rate. These comparative percentage rates, therefore, are probably closer to each other than the statistics indicate.

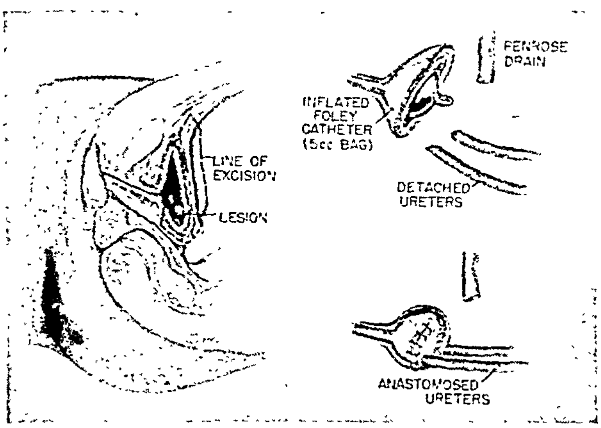

Fig. 1.—Subtotal cystectomy with reanastomosis of ureters; residual bladder sufficiently large to close over inflated 5—cc. Foley bag catheter; regeneration complete in three to eight weeks.

Regardless, for the superficial or deep infiltrating bladder cancers, cystectomy offers the patient little more, perhaps less, than can be obtained with the standard simple segmental resection. In addition, patients having segmental resection are not subject to having their urine or feces drain into a collection apparatus attached to the abdominal wall. Current statistics, therefore, do not justify the opinion that "poor" or "inadequate" cancer surgery has been performed if anything less than cystectomy is used in treatment of superficial or deep infiltrative vesical cancer. The statistics do indicate that segmental resection is equally as curative, if not more so, as total cystectomy. This is applicable for all but the two exceptions previously mentioned of multifocal or bladder neck cancer.

Conclusions.—Apparently cystectomy is unnecessary and too radical a procedure. Transurethral resection is inadequate treatment to achieve maximum potential cure rate for bladder cancer for all stages and grades. This leaves segmental resection as the most desirable of the three methods. Based on these considerations and statistics, we have been exploring the possibilities of subtotal cystectomy for treatment of bladder cancer in an effort to improve the present favorable statistics obtainable with segmental resection.

Bladder Regeneration After Subtotal Cystectomy

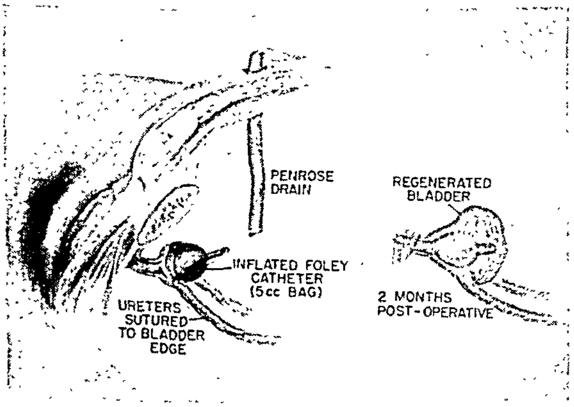
We have demonstrated that after subtotal cystectomy in the dog, the entire bladder wall regenerated. We first reported clinical use of this remarkable regenerative ability of the urinary bladder in 1953.[1] In the human as well as the dog, the new bladder is composed of all layers seen in the normal bladder. From a clinical standpoint, regeneration always occurs except if the urine is diverted from the area. The regeneration into the form of a hollow viscus is due to an unknown chemical inductor in the connective tissue matrix immediately beneath the epithelium of the urethra at the vesical neck or the terminal ends of the adjacent ureters or both.

Procedure.—In order to study the procedure of subtotal cystectomy and bladder regeneration, cancers at various sites in the bladder and of varying stage and grade were included in the series on an unselected basis. All patients with papillomas were excluded from the series. Treatment was classified as palliative only when the cancer had spread beyond the bladder to the pelvis or to multiple lymph nodes or chest or bones.

A diagnosis of cancer was established in each patient by a transurethral resection of the entire lesion with the patient under general anesthesia. This general rule of complete transurethral resection of the lesion was adhered to throughout the study with the exception of huge bladder cancers. In this latter situation biopsies of multiple areas were performed with the resectoscope. After resection of the cancer, the entire base of the lesion, including a 1-cm. margin peripheral to the edge of the lesion, was electrocoagulated. Four to seven days later subtotal cystectomy was performed. Based on location, size, and depth of infiltration of the cancer, varying percentages of the bladder were removed. The precise amount of excision had to be determined at time of operation, for endoscopic appearance and bimanual examination were of little assistance. Lesions of low grade and low stage usually resulted in excision of only about 30 to 50% of the bladder. Lesions of moderate grade and moderate stage which were larger in circumference were excised by the subtotal technique in which all but a piece of the bladder was removed. Regardless of amount of vesical excision, whenever possible a small piece of the bladder was salvaged as it accelerated regeneration and resulted in a larger definitive bladder (fig. 1). In all patients the peritoneum attached to the bladder, the perivesical fat, and the bladder segment were removed en bloc.

As the objective of the operation was to excise cancer, no attempt was made to salvage one or both ureteral orifices if doing so would appear to compromise adequate excision of the lesion. Consequently, one or both of the orifices were often sacrificed. The ureter or ureters were reanastomosed to the remaining bladder segment just prior to complete closure of the segment. A standard fish-mouth ureteroneocystostomy was performed.

In most patients it was possible to close the remaining bladder segment, regardless of its shape, over an inflated 5-cc. bag of a Foley catheter. In 12 patients, it was impossible to close the residual bladder segment due to its small size. In these patients the ends of the ureter or ureters were spatulated and anastomosed to the edge of the residual piece of bladder with a single suture (fig. 2). In a few patients with lesions at the vesical neck even this small bladder segment had to be excised, thus resulting in total cystectomy. The ureters of these latter patients were managed in one of two ways: A large isolated segment of rectosigmoid was anastomosed to the urethra, the proximal end of the segment was closed, and the ureters were sutured into this piece of colon. Continuity of intestine was established with standard end-to-end closure. In several male patients, however, true total regeneration of the bladder developed as the ends of the ureters were spatulated, and by a single suture each was attached to the anterior rectal wall as close as possible to the urethra (fig. 3).



PENROSE DRAIN
REGENERATED BLADDER
INFLATED FOLEY CATHETER (5cc BAG)
URETERS SUTURED TO BLADDER EDGE
2 MONTHS POST-OPERATIVE

Fig. 2.—Subtotal cystectomy; remaining bladder not large enough to close; ends of ureters spatulated and sutured to open bladder segment; regeneration complete in 4 to 12 weeks.

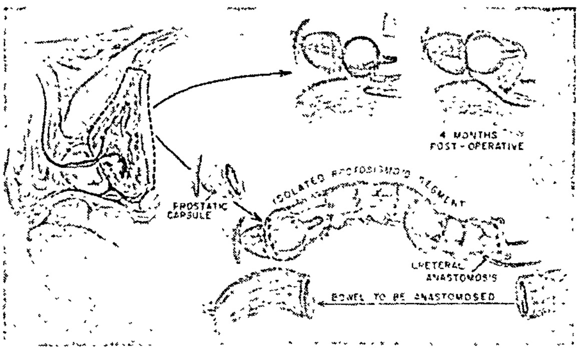


Fig. 3.—Total cystectomy demonstrating alternate methods of ureteral management used. Note peritoneum and perivesical fat excised with bladder.

In all patients an empty Penrose drain was inserted through the abdominal wound to the bladder or the bladder area. As the pelvic peritoneum had been excised with the lesion, the pelvic floor could not be reperitonealized in any of the patients. The Penrose drain was removed approximately four to seven days after suprapubic urinary drainage had stopped and one day after removal of the urethral catheter. If suprapubic drainage persisted for longer than 14 days, the drain was removed. The catheter was left in place for four to seven days after suprapubic drainage ceased.

Results

Essentially this method of management of bladder cancers consists of two surgical procedures: a preliminary complete transurethral resection of the lesion followed by a subtotal cystectomy. It has been of interest to study these subtotal cystectomy specimens. Such specimens of some superficially infiltrating lesions, as determined by the earlier transurethral resection, have later demonstrated that tumor cells were present in the adventitial lymphatics or lymphatics of the bladder wall some distance from the site of the original lesion. It was particularly disquieting to observe cancer cells in adventitial lymphatics when meticulous search of the transurethrally resected cancer site failed to reveal any residual cancer (fig. 4). While only a few such cases were observed in this study they represent definite, conclusive failure of cure by transurethral resection of superficial infiltrating cancer. These patients tend to support our earlier observations relative to the circumferential spread of cancer within the lymphatics of the bladder wall.[2] These findings also prompted institution of our existing program in which peritoneum and perivesical fat as well as the bladder segment with its tumor are removed in a block as this fat or adventitia surrounding the bladder may contain cancer cells.

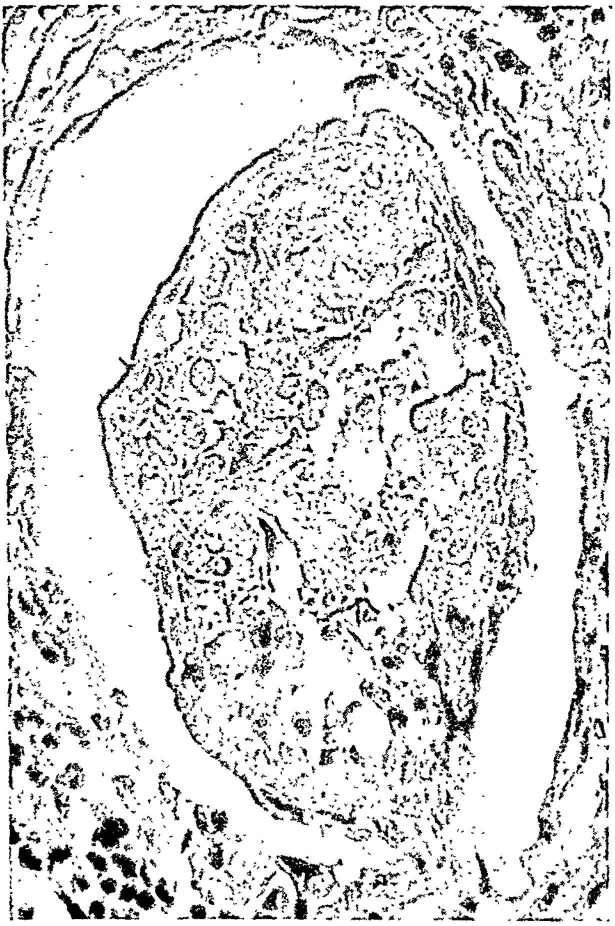

Fig. 4.—Carcinoma in lymphatic of perivesical tissue (× 300).

No intestinal complications resulted from inability to reperitonealize the pelvis. Peritonitis did not complicate the postoperative course. Ileus has been a troublesome factor in several patients but has never been greater than that observed in certain individuals after routine renal surgery. Early in the study two ward patients probably developed unsuspected electrolyte imbalance which became fatal. Electrolyte imbalance is assumed as no demonstrable cause of death was detected at autopsy. No subsequent ward or private patients have died from electrolyte imbalance. No electrolyte imbalance has been seen that required significant treatment. One private patient with a deeply infiltrative epidermoid (squamous cell) carcinoma died of a pulmonary embolus approximately eight weeks after subtotal cystectomy.

Most patients were sent home 10 to 18 days after operation, while still draining urine suprapubically. As might be expected, the less bladder excised the sooner the patients were discharged from the hospital. The urethral catheter usually drained very little for the first week or two postoperatively. Most patients stopped draining urine from the suprapubic wound within three to five weeks after operation. Two patients having total cystectomy without ureteral transplantation drained urine slightly in excess for four months. All patients regenerated a new bladder which closed spontaneously.

One out of five patients (20%) developed some degree of ureterorenal reflux. This has on occasion been accompanied by minimal to moderate degrees of ureteral dilatation and hydronephrosis. The ureterectasis and pyelectasis usually decreased once definitive bladder size was attained (fig. 5). While ureterorenal reflux has been observed as part of this study, in eight years' experience with the procedure a clinical problem was presented in only one instance. That patient had severe, recurrent pyelonephritis which required vigorous antibiotic and chemotherapeutic drug therapy. It should also be reported that ureterorenal reflux can develop in a ureter which has not been disconnected and reanastomosed to the bladder. The significance of this observation is not clear but is under study at present.

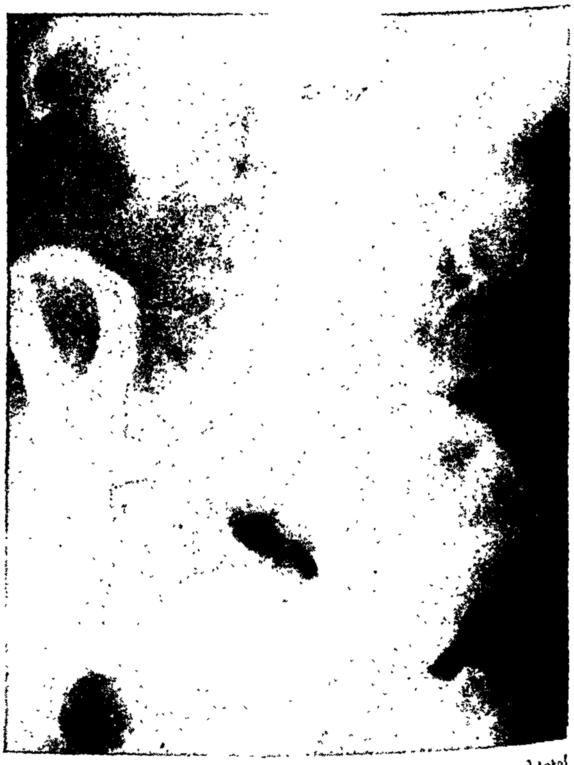

Fig. 5.—Oblique cystogram taken one year after subtotal cystectomy demonstrating ureterorenal reflux; patient asymptomatic, urine sterile.

Nocturia and diurnal urinary frequency were marked from one to two months postoperatively. At the end of four to six months none of the patients in the series had nocturia of more than two to three times each night. During the day, none voided more frequently than once every two to three hours. Cystographic appearance of the bladder demonstrates a viscus which is quite irregular (fig. 6). Cystograms taken at 4 months, 6 months, and 12 months show that there is an increase in bladder size from the fourth to the sixth month. Bladder capacity probably does not increase appreciably after 12 months. The mean bladder capacity for the patients studied ranged between 175 to 410 cc. of urine. The patient with 175 cc. of bladder urine capacity had total cystectomy with complete bladder regeneration. Only one patient in every 10 to 15 will have any residual urine. Residual urine has never been measured at more than 20 cc.

In all patients regeneration of the bladder occurred. In only one patient was the bladder capacity exceedingly small. This was in an individual 79 years of age. In a personal communication Lewis has noted also that patients of the very old age group regenerate with a small bladder capacity after a subtotal cystectomy.

The total number of patients followed for a full five-year postoperative period is too small to permit standard statistical comparison with other methods of management at this time. These results will be reportable later.

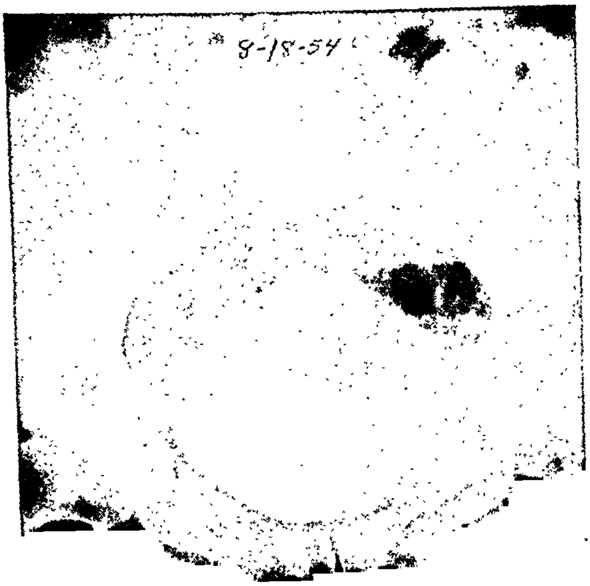

Fig. 6.—Cystogram taken one year after 90% subtotal cystectomy demonstrating irregularity of regenerated bladder; no residual urine.

It has been possible to obtain full thickness biopsy specimens of the regenerated bladder via the suprapubic route. Photomicrographs of the regenerated bladder demonstrate fibrous tissue interlaced with muscle fibers (fig. 7). These muscle fibers are not always continuous through the bladder wall. They originate as separate isolated muscle fibers in the fibrous bladder sheath (fig. 8). The presence of muscle in the regenerated bladder undoubtedly accounts for the notable lack of residual urine in all but a few of the patients studied. The fact that the muscle fibers initiate at individual sites within the fibrous tissue tends to support the view that muscle fibers are not an extension of ureteral or urethral musculature. Apparently the proximity of the urethra and ureters serves as an inductor phenomenon for development of muscle fibers from the totipotent mesenchymal-fibroblastic cell.

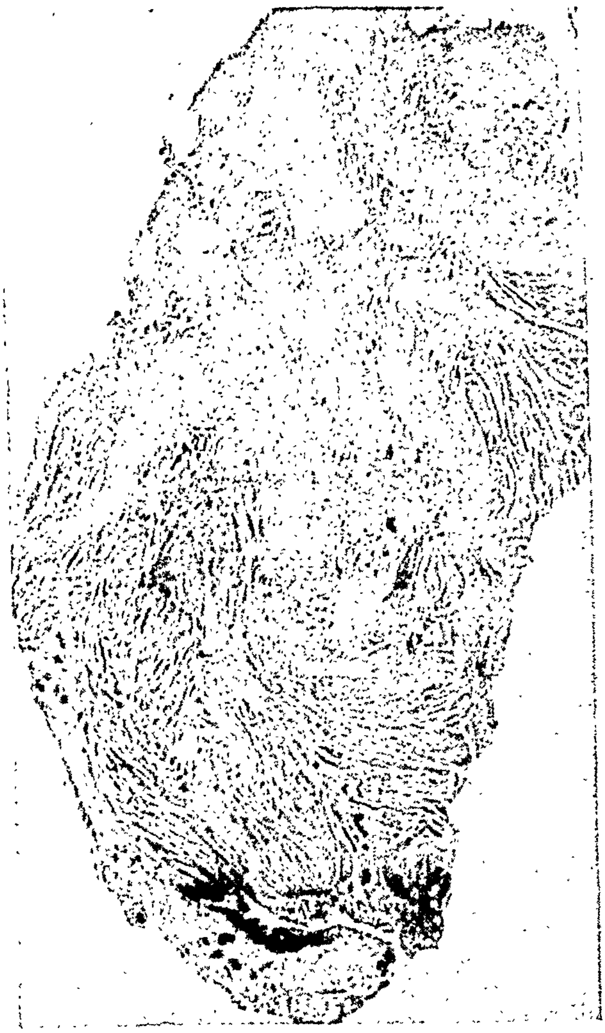

Fig. 7.—Low magnification of full thickness biopsy of regenerated bladder wall; muscle and fibrous tissue present; epithelial surface at top, adventitial surface at bottom.

Patients who had extensive lesions of the bladder were also subject to subtotal cystectomy as a palliative procedure. It was found that eliminating the tumor mass and reanastomosing the ureter to the residual bladder made these patients considerably more comfortable. In addition, the patients had the distinct advantage of being able to void via normal channels rather than using urinary or colostomy collection bags attached to the abdominal wall. In several patients the huge cancer had involved the bony walls of the pelvis and subtotal cystectomy could not be used. It is our opinion that very little could have been accomplished by any other type of surgical procedure with this type of advanced bladder cancer.

It was not hoped that any of the patients with advanced bladder cancer treated by total cystectomy would be cured of their disease. It should be added, however, that several of them are alive four, five, and seven years after subtotal cystectomy and are to date clinically free of cancer.

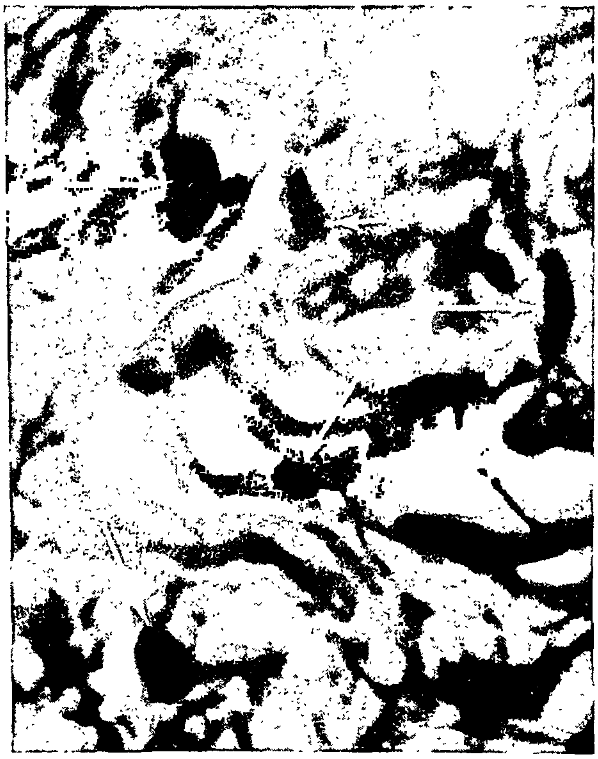

Fig. 8.—Regenerated bladder wall; arrows indicate isolated development or origin of separate muscle fibers. Masson stain (× 1,225).

Comment

The percentage of patients having bladder cancer which is potentially curable by transurethral or suprapubic segmental resection should be increased by use of subtotal cystectomy. Present statistics indicate that simple segmental resection effects a five-year survival rate equal to that of total cystectomy. It is certainly possible that those patients cured by total cystectomy could reasonably be expected to be cured by subtotal cystectomy. Of great importance to the patient is that with subtotal cystectomy the ureters are not transplaned elsewhere than to the bladder. As a consequence, these patients void via the urethra with full urinary control.

Subtotal cystectomy should be considered as a large segmental resection in which ureteral orifices are not spared at the expense of leaving cancer cells within the bladder. Subtotal cystectomy is a simple procedure which can be performed readily at any hospital by any urologist.

Many urologists do not like suprapubic segmental resection, as it is felt that manipulation of the tumor cells can disseminate these cells outside the bladder. This objection has been eliminated as patients in this series had preliminary transurethral resection of the entire lesion prior to subtotal cystectomy.

Patients with deeply infiltrating lesions at the vesical neck are probably not suitable candidates for subtotal cystectomy. These patients as well as those with proved multifocal cancer undoubtedly require total cystectomy. As described above, this does not imply that ureters must be diverted elsewhere.

While subtotal cystectomy is sometimes associated with prolonged suprapubic urinary drainage, this is no objection to the procedure. With cystectomy and transplantation of the ureters to an ileal pouch, there is permanent urinary drainage from an opening on the abdominal wall.

Urologists who perform lymphadenectomy at time of cystectomy will find some difficulty if subtotal cystectomy is used. In essence, the remaining bladder segment is in the way of the operator. Lymphadenectomy can be performed with subtotal cystectomy as completely and efficiently on the side containing the tumor, however, as when total cystectomy is employed.

The 20% incidence of ureterorenal reflux after subtotal cystectomy may appear as a major complication. It has not been so. We are well aware of the disadvantage of ureterorenal reflux, having been among the first to investigate and report on reflux after ureterointestinal anastomosis.[6] To date, the only adverse clinical effect of reflux we have seen is one patient with a severe unilateral pyelonephritis. This is considerably less than seen with any type of ureteral transplantation. Furthermore the incidence of radiographic renal and ureteral abnormalities is greater after any type of ureterointestinal anastomosis than the incidence of reflux in patients after subtotal cystectomy. By preservation of the normal voiding mechanism, subtotal cystectomy has advantages that do not require further discussion and outweigh any of the complications that have been encountered during eight years' experience with the procedure.

The use of subtotal cystectomy in patients with far-advanced bladder cancer appears to be worthwhile as a palliative procedure, as it removes the large irritating and often bleeding mass. As the procedure permits reimplantation of an involved ureter to a normal segment of the bladder, these patients void with normal urinary control. In most patients with far-advanced bladder cancer, when the procedure can be used at all, it is preferred by us to any other we have previously employed.

Summary

Subtotal cystectomy in treatment of bladder cancer of superficial or deep infiltrating types is presented as a substitute for other surgical methods now universally employed. Bladder regeneration after subtotal and total cystectomy indicates that muscle formation originates from the totipotent mesenchymal cell and not as direct extension from ureteral or urethral musculature.

PREVENTIVE AND AVIATION MEDICINE IN PRIVATE PRACTICE

Russell J. Vastine Jr., M.D., Niles, Mich.

It is possible to devote a private practice to preventive and aviation medicine. Its objective is to supply people with a particular type of health service that will enhance well-being and prolong life. Its essential features are thorough examinations and subsequent instruction. Its application is especially natural in connection with aviation, for there is evidence that examinations of pilots have often been perfunctory and that there are ambulatory persons who should not fly. The program of history-taking, physical examination, and laboratory tests here outlined has been found efficient. Such a survey should be an annual affair for both private and airline pilots, regardless of rating. It is easily adapted to all persons interested in maintaining their health.

Most authors have written that the private practice of preventive and aviation medicine is not feasible. With this I disagree. However, I am taking a different approach to the subject than most persons. We must first come to an understanding of definitions and responsibilities of a private practice of this sort.

It is impossible for one to establish a practice to supplant the public health officer. It is impossible to furnish epidemiologic studies for communities and to supply diagnostic laboratory studies, such as a good public health office does. It is, however, possible to supply individuals with a particular type of health service that will greatly enhance their well-being and will, in the long run, statistically increase their longevity. This, then, is the objective of a private practice devoted to preventive and aviation medicine.

Fitness in Flying

Aviation medicine is a special branch of preventive medicine. Just as the pilot practices preventive maintenance for his airplane, so must he practice preventive maintenance for himself. As you know, the pilot is required by law to undergo periodic medical examinations in order to maintain his license. It is in this field of medical endeavor that the medical profession has failed miserably. The caliber of examination to which these persons have been exposed is outrageous. Medical certificates

---

Read before the Joint Meeting of the Section on Preventive Medicine and the Aero Medical Association at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

have been issued with only a minimal examination, sometimes with no examination at all. We have insisted on periodic examinations for safety reasons and then have failed to perform them satisfactorily. No wonder, then, the pilot feels distrust for those of us who wish to maintain air safety. No wonder, then, the pilot feels that the medical standards are useless. Physical fitness is important to flying safety, but how can this be proved when we have such poor medical supervision of flying personnel?

To cite an example of the importance of physical fitness to flying safety, I recall a pilot I examined for an airline transport pilot's rating. Using the Civil Aeronautics Administration's chart for testing near vision, I found this man could not read the bottom paragraph with either eye and could only barely make it out with binocular vision. His chief complaint was with night vision. He had trouble reading his maps at night because he had to hold them close to his face to protect the night vision of his co-pilot from the flashlight he used. This man admitted that it had been at least four years since he had been able to read this bottom line. He had been examined at six-month intervals during this period and had never been told his eyes needed correcting lenses, and his medical certificate had never been marked with a limitation. This visual defect was severe enough to cause this man to refrain from filing flight plans unless his radio had been set previously, because he could not read the dials. Here is an excellent pilot endangering himself and all those in the airplane because of a physical defect. His new glasses have increased flying safety for all concerned.

Annual Health Survey

Since we have already stated the objective of a private practice devoted to preventive and aviation medicine and since we have discovered that aviation medicine is preventive medicine, let us set about outlining the responsibilities of this type of practice. Probably the most outstanding service to be offered by this type of practice, and the one in which there is the greatest need for action soon, is the periodic examination. My personal opinion is that an annual examination is adequate unless some defect be found that would dictate more frequent ones. I would prefer to call this examination an annual health survey. I am sure that no one in his own practice would ask a patient to return for such a survey more often than once a year. Pilots are no different. This survey should be an annual affair for all pilots, regardless of rating. The private pilot uses the same air space as the airline pilot and is subject to the same stresses of flying and living. While cost is a factor in the survey I am about to recommend, it is no more costly than seven hours' rental of a Piper Cub or a 50-hour inspection of an airplane.

A complete history of present complaints, along with a searching review of symptoms by systems, should be the first step in the annual health survey. This should be taken by the examining physician for what appear to be obvious reasons, but perhaps some of them should be stated. The examiner will acquaint himself with the type of person he is examining and will gain insight into the complaints the patient has. Most of all, he will be able, if he knows how to fly himself, to get a fair picture of the type of pilot he is examining. This latter point is where we all fall down. Industries using aircraft, as well as the airlines, are interested in finding a simple means of discovering if a pilot will be a potential cause of accident before they hire him. By making a personality analysis and honestly checking it with some one who has flown with the pilot, we will some day be able to put on paper what we look for and provide a long-needed answer. This I have done in my practice. I have been lucky in my decisions. The reason for this is that I am a pilot myself and have a pilot's point of view. If you have never been in a tight squeeze in an airplane or never have been faced with making rapid decisions while in an airplane, it is sometimes difficult to understand what the pilot is telling you. A few hours of flight time is not the answer. The taking of a thorough personal and family history is also important in this phase of the annual health survey.

The physical examination should be done with care and precision, noting any and all defects, no matter how slight. This will some day pay excellent dividends when the examinations are reviewed with an eye toward determining the natural history of some particular disease. We do not know now what may be important later, so we must not omit anything. Included in the physical examination should be a pure-tone audiometry. Many early hearing losses, particularly in those persons who are exposed to noise, will be found only if this is done. No physical examination is complete without a sigmoidoscopy. This can easily be done without preparation on the part of the patient. One of the disposable enemas, given when the history has been completed and before the physical examination is begun, will clean the distal portion of the intestine nicely so that the scope can be passed to 25 cm. with ease. Only rarely does the enema need to be repeated. This method is acceptable to the patient. I have not had to use air insufflation in a single case. More complaints have been registered during the rectal examination than during the sigmoidoscopy.

If at all possible, prostatic secretion should be obtained for examination under the microscope. I have been amazed at the number of cases of symptomless, mild prostatic disease I have found that respond well to sitz baths.

Examination of the eyes should include testing of both distant and near visual acuity and visual fields. Early glaucoma can be helped. While tonometry is ideal, I have not yet become convinced that it ought to be made a part of routine procedure.

In order to complete the annual health survey, certain ancillary studies should be done. These include an electrocardiogram, a two-meter posteroanterior chest x-ray, a complete urinalysis, a complete blood cell count (or a hematocrit determination and differential count), and determination of sedimentation rate and nonfasting blood sugar, blood urea nitrogen, and blood cholesterol levels. Serologic examination is also done and, for the patient's own satisfaction, blood type and Rh-factor determinations. Most of these studies need no discussion as to their usefulness, but perhaps a word should be said about the cholesterol level determination. This was chosen for two reasons, the first of which is more of a research problem. The ever-increasing discussion of cholesterol and its relation to heart disease and arteriosclerosis makes it worthwhile to make routine determinations to perhaps help in the study of the natural history of disease. The second reason for this choice is that it offers a simple means of roughly measuring thyroid function. My patients come to me on a fly-in basis, and it is not feasible to examine these persons in a fasting state so that the basal metabolic rate can be determined. Nor is it convenient to draw additional blood in chemically clean glassware for protein-bound iodine determination. This would also increase the cost of the annual health survey. Thus, the blood cholesterol level is determined. I have stated that these blood specimens are drawn on the nonfasting patient. This, I feel, is a truer picture of the function of the organs involved in these studies than is the fasting state. As a part of the history interview, I review the diet for the past 24 hours. I note the time of the last meal and the time the blood was drawn. Some day I will be able to review these examinations, calculate roughly the amount of food intake, and establish normals for the nonfasting state. It may have many other ramifications that are not now readily noticeable.

The annual health survey I have just reviewed consumes between two and three hours. The cost at present has been set at $70. For what is done, I feel this is a realistic fee. One will never get rich doing this sort of thing, but he won't starve. The x-rays are read by a radiologist, and the laboratory work, except for the blood cell count and urinalysis, is done in a recognized laboratory. The patient is getting a rather extensive review of his health at a reasonable cost. By performing these annually, an excellent case study is established so that even the slightest change may be readily found. This then affords an opportunity for diagnosis of symptomless disease and thereby prevention of serious illness.

Further Responsibilities of Aviation Medicine

This is not complete for the prevention of disease because we are not yet able to follow the natural history of illness, but I sincerely feel that what I am doing will some day offer some of the answers. An objective is also to make flying safer and prolong the productive life of the pilot.

Another responsibility of this type of practice is to the passenger. Regardless of the stand of the airlines, there are certain ambulatory persons who should not fly. The practitioner of aviation medicine must be aware of these ailments and advise the pilot and the passenger of limitations to be observed in flight. Corporate flying increases the exposure of this type of person to the effects of flying without supervision. Very few companies have any rules regarding restriction of flight for their personnel. Advice should also be available concerning prevention and treatment of the diseases incident to flight, such as aerotitis and aerosinusitis. The use of a nasal spray, at the proper time, will reduce pain and lost work.

The physician in this kind of practice should also be available for assistance in establishing retirement and temporary grounding policies that will add to the peace of mind of the pilot. This will give him more mental space for flying. The physician should take an active part in the training of the pilot. He should be called on to teach first aid and to give instruction in the medical aspects of flight. Demonstrations of the effects of oxygen want are more valuable than all the words one can command.

Selection of aircraft and revision of present aircraft always present problems. There are few people who can do it well, but the physician can help in the fields of passenger comfort, cockpit engineering, cabin ventilation, availability of oxygen equipment, and its selection, if its need is anticipated. Also, advice concerning safety features should be forthcoming.

Conclusions

There is great opportunity in this field of aviation medicine for research on an individual basis in matters concerning aviation as well as in matters pertaining to the prevention of disease. The more of us who will participate in this type of program, the more facts will we accumulate to aid all doctors in their effort to control disease.

While this practice is intended to be devoted to the pilot, it is easily adapted to all persons who are interested in the maintenance of their health. Until aviation personnel can be ethically told and can accept what I am trying to do, my income is dependent on nonflying persons.

TWENTY-YEAR STUDY OF PHYSIOLOGICAL MEASUREMENTS IN ONE HUNDRED SENIOR AIRLINE PILOTS

George J. Kidera, M.D., Chicago

Unusually complete sets of physical and laboratory measurements were obtained from 100 men who had been participating actively in the piloting of commercial aircraft for 20 years. This group underwent a rigorous process of selection not only at the beginning but also throughout the duration of their careers as fliers. The average age was 30.5 years at the beginning and 50.5 years at the termination of the study. The most striking changes were a gain of 5.4 kg. (12 lb.) above the initial mean weight of 71.4 kg. (157.5 lb.), a decline of 969 cc. from the initial mean vital capacity of 4,962 cc., and an increase of 5.0 and 4.5 cm., respectively, in the girth of the abdomen and unexpanded chest. Blood pressure and heart rate remained remarkably constant, but impairment of near vision was striking, since 91 men required presbyopic correction by 1957. Audiometric losses were found, amounting to 2.85% for the right ear and 4.6% for the left, but these were roughly equal to those found in the general population. There was no evidence, in this study, of occupational predilection for any particular physical disorder.

For several years physicians of commercial airlines who perform periodic physical examinations on flight personnel have been requested by various groups studying aging to report their findings on pilots in order to document any particular premature physiological deterioration in this group. The airline pilot was recommended for this study for several reasons. First, the airline's type of flight physical examination is complete, consisting of a history and careful examination. Particular reference is made to the special senses and laboratory tests, such as routine chest x-ray, routine electrocardiograms, stress electrocardiograms, sedimentation rate, and complete blood cell counts.

If a deviation from normal is noted in any phase of examination, the airline medical department's approach is slightly different than that in private practice. It behooves the airline to establish a definitive diagnosis and assess and evaluate completely the deviation, regardless of its immediate clinical significance. An example of this would be the detection of minor T-wave changes in a pilot who previously had normal electrocardiographic tracings. In private practice one might recommend further studies, such as thyroid function, stress electrocardiogram, total blood fat determination, and ballistocardiogram. The private patient may not be disposed to undergo such an exhaustive study. When such a deviation is detected in a commercial airline pilot, it is absolutely necessary that the condition be assessed and no avenue of study is left unexplored, in view of the responsibilities incident to the pilot's profession.

Another reason for selecting airline pilots for this study is the fact that these men are periodically examined by the same group of full-time company doctors. Laboratory procedures, even though a 20-year span is covered by this study, have been performed by not more than five different laboratory technicians. This consistency of professional personnel tends to result in more accurate study data than if results from many physicians, clinics, and laboratories are reviewed.

The question whether irregular hours and hypoxia might be factors in deterioration could also be studied by evaluating the physical condition of airline pilots, since many of the senior captains flew in the days prior to pressurization of aircraft and were exposed regularly to altitudes of 10,000 to 14,000 ft. With the advent of pressurized aircraft, this exposure is limited to usually less than 8,000 and more frequently to 5,000 or 6,000 ft.

Materials and Methods

A study of airline pilots does not lend itself to a study on aging per se, since the age group represented cannot be considered aged and there are not enough commercial airline pilots over 50 years of age to give valid statistical criteria. Consequently, this report is concerned with what could be referred to as a middle-aged group. These records are a continuous account of the physical status of these men from the time of their preemployment examination to their current company-prescribed physical examination. These pilots not only receive a thorough annual physical assessment but also must be given medical clearance for resumption of flight duties after any illness or injury.

Flight personnel are also encouraged to consult the physicians not only on personal problems but also on any medical problems relating to their families. This gives the flight surgeons an opportunity to visit and consult with the pilots four to five times per year. One of the most important factors in attaining good liaison with the flight personnel is the position of the medical depart-

Read before the Joint Meeting of the Section on Preventive Medicine and the Aero Medical Association at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

ment in the company's organization. The United Air Lines medical department does not report to any other administration or agency. All medical records, reports of consultations, and results of examinations are confidential and are made available only to the pilot. Management is advised that an individual is physically qualified or disqualified for further flying, and no data are furnished to anyone unless specifically requested in writing by the pilot. This doctor-patient relationship is of utmost importance in building up free communication between the flight surgeon and the pilot.

At the initiation of this study in 1937, the ages of these 100 airline pilots ranged from 25 to 39 years, with an average age of 30.5. In 1957, the average age was 50.5 years and the range 45 to 59.

Results

A consideration of actual findings of those factors which lend themselves to a quantitative comparison follows.

In 1937, all 100 pilots had distant vision of 20/20 or better in each eye. By 1957, 20 needed glasses to bring their vision to 20/20. The poorest vision in this group was 20/50 for the right eye and 20/67 for the left. Dimond's report [1] of a small series of airline pilots is of interest. In those with a preemployment cycloplegia of +0.25 to -0.25 D., the defect in some remained stabilized but there was a physiological and developmental trend toward myopia. With a preemployment cycloplegic refraction of +0.675 D. or more, most pilots will continue to have hypermetropia (hyperopia) with 20/20 vision throughout their anticipated long span of duty. Consequently, 20/20 vision and a manifest or homatropine-produced hypermetropic reserve of +0.50 D. or more in the early to mid-20's is desirable in the prospective airline pilot.

Near vision for the group was calculated as 1 on the Jaeger system in 1937. By 1957, 91% required presbyopic correction (at an average age of 44.5 years). Other eye findings are shown in table 1.

TABLE 1.—*Average Eye Findings in 100 Commercial Airline Pilots Over Twenty Years*

	1937	1957
Depth perception, mm. (Howard-Dohlman)	11.10	12.99
Abduction, D.*	6.11	5.65
Adduction, D.	13.80	13.05
Esophoria (20 ft.), D.	1.48	0.76
Exophoria (20 ft.), D.	0.42	0.28

* Diopters.

In the general population one sees a tendency toward an increase in adduction in the development of exophoria, especially with accommodative problems. This was not noted in the pilot group, since they were given corrective lenses for accommodative problems early. The average depth perception was essentially unchanged, as would be expected since depth perception is primarily a product of good binocular vision.

In 1937, five had hearing less than 20/20 when using the spoken voice test. This ranged from 15/20 to 18/20. In 1957, the lowest value was 5/20 hearing for the spoken voice in one ear. In 1937, the voice-range audiometric findings were practically normal, but some high-tone loss was noted. The average loss was 12% for the right ear and 13.8% for the left ear. In 1957, 61 showed a loss for the frequencies above 4,000 cps, 16% for the right ear and 17% for the left ear. In 1957, with use of the method for calculating percentage hearing loss recommended by the American Medical Association Committee on Medical Rating of Physical Impairment, a loss in the 500-to-4,000-cps range was found of 2.85% for the right ear and 4.6% for the left ear. These audiometric losses compare favorably with those of ground personnel of similar ages.

TABLE 2.—*Average Blood Findings in 100 Commercial Airline Pilots Over Twenty Years*

	1937	1957
Red blood cell count, cu. mm.	5,462,000	5,315,400
Hemoglobin level, Gm. % (Sahli)	15.35	15.82
White blood cell count, cu. mm.	10,450	9,500
Sedimentation rate, mm./hr. (Cutler)	7.9	6.8

Height averaged 69¾ in. (177 cm.), and there was no significant change over the 20-year period. In reviewing the weight gain it was anticipated that a rather sizable increase in weight over the 20 years would be found. This was not the case. Weight in 1937 averaged 157½ lb. (71.4 kg.), with a variation between 211 and 127 lb. (96.2 and 57.6 kg.), while in 1957 the average was 169½ lb. (76.9 kg.). The heaviest man weighed 221 lb. (111.2 kg.) and the lightest 136 lb. (61.7 kg.). An average weight gain of 12 lb. (5.4 kg.) during a 20-year span was considered excellent. This is further emphasized in the light of a report by Captain Huber of the U. S. Navy (Huber studied a group of Navy pilots and found an average weight gain of 29 lb. [13.2 kg.] per man over a 10-year period). Unexpanded chest measurement in 1937 averaged 35.25 in. and the abdominal measurement 31.43 in. Twenty years later the values were 37.04 and 33.4 in. respectively.

Pulse rate, blood pressure, and vital capacity were periodically determined, and in 1937 and 1957 the average compared as follows: pulse rate, 65.9 and 65.5 per minute; blood pressure, 114/72 and 115/78 mm. Hg (ranges, 96/56 to 154/78 in 1937 and 98/58 to 158/84 in 1957); and vital capacity, 4,962 cc. and 3,993 cc. (ranges, 3,100 to 5,900 in 1937 and 3,000 to 4,850 in 1957). The highest recorded blood pressure was 158/84 mm. Hg; this occurred on a single reading, in 1957, in the same man who, in 1937, had the highest reading, 154/78 mm. Hg. Similarly, the man who, in 1937, had the lowest blood pressure recording, 96/56 mm. Hg, also had the lowest reading in 1957, 98/58 mm. Hg. The vital capacity from 1937 to 1950 was measured by a water spirometer. Subsequent to 1950, the Propper compact spirometer has been used.

The blood findings at every physical examination proved to be extremely consistent. These are summarized in table 2.

In an attempt to evaluate physical status, absenteeism over the 20-year period was studied in this group of pilots. There were 8,267 days lost, which amounts to slightly over 4 days per year per man. The nature of the illness responsible for absenteeism is strikingly similar to that reported by industry in general, and it compared almost to the number for a similar group of ground personnel within the company, with one exception. Upper respiratory infections accounted for approximately 40% of the days lost. The next highest percentage, and this is the exception, was absence due to trauma. This acounted for almost 20% of the pilots' absenteeism. Traumatic injuries resulted in 1,893 days lost. While this is high in relation to illness, it is of interest to note that the traumatic injuries were primarily incurred in recreational activities, such as baseball, skiing, working with power tools, and other "do-it-yourself" programs. The pilot group is usually an athletic group with considerable time for hobbies and diversion, which apparently exposes them to a greater incidence of trauma. The remainder of the causes of absenteeism ranged through all of the illnesses and injuries to which man is heir. Other than traumatic injuries, there was no prevalence of any diseases as compared to nonflying personnel.

Summary

Physical and laboratory findings in 100 senior airline captains over a 20-year period were studied. The homeostasis presented by this group was impressive. In spite of 20 years of their active participation in piloting commercial aircraft, there was no evidence of premature deterioration or predilection to any particular medical or surgical condition.

ROLE OF THE HUMAN FACTORS BRANCH AT THE AIR FORCE FLIGHT TEST CENTER

Lieut. Col. Burt Rowen (MC), U. S. A. F.

The Air Force Flight Test Center (AFFTC) is located in the Mojave Desert, approximately 75 nautical miles northeast of Los Angeles, and occupies approximately 300,000 acres of land. The physical location of the center is built around the 65 square miles of Rogers Dry Lake, and it is estimated that this concrete-hard lake bed, which serves as a natural emergency landing field, has saved over 630 million dollars in hardware alone since April, 1946. Naturally, no estimate is placed on the lives saved. The AFFTC includes a rocket engine test facility, a high-speed sled track, a precision bombing range, an all-altitude speed course, the U. S. A. F. Experimental Flight Test Pilot School, and the high-speed flight station of the National Advisory Committee for Aeronautics.

Since 1949, U. S. A. F. flight testing has been divided into eight phases by Air Force Regulation 80-14. These divisions are as follows: phase 1, air

> *The mission of the Human Factors Branch at the Air Force Flight Test Center is to study the design and functional characteristics of research aircraft and weapons systems as related to human capabilities, to evaluate the man-machine relationship, and to recommend appropriate changes. Today almost every contractor in the aircraft industry has a human factors or a human engineering staff. It is gratifying to realize that there is a large human engineering work force-in-being dedicated to tailoring an aircraft to suit the human operator. Everyone concerned with instrumenting, equipping, and modifying cockpit arrangements of piloted aircraft has realized the necessity of relieving the crew member of as many details of aircraft operation as possible, if missions are to be successful.*

Chief, Human Factors Branch, Directorate of Flight Test, Air Force Flight Test Center, Edwards Air Force Base, California.

Read before the Joint Meeting of the Section on Preventive Medicine and the Aero Medical Association at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

worthiness; 2, contractor compliance; 3, design refinement; 4, performance stability; 5, all-weather; 6, functional development; 7, employment suitability; and 8, unit operational employment.

In the near future a revised Air Force Regulation 80-14 will change the U. S. A. F. flight testing concept. The new regulation provides for earlier and increased participation by the using commands in the testing of new systems planned for the U. S. A. F. inventory. The purpose of this revision is to assure the earliest possible introduction of proved systems into the inventory and minimize the impact on the combat capability of using commands.

The new test concept calls for integrated test programs with provisions for participation of the using commands and other interested agencies in a combined test force. It will establish the following three general categories of testing: 1. Subsystem development and evaluation. This will correspond to phases 1, 2, and 3. 2. System development and evaluation. This will correspond to phases 4, 5, and 6. 3. System operational evaluation. This will correspond to phases 7 and 8. Pending formal publication of the revised regulation, all commands are directed to cooperate in initiating action for execution of test programs on new systems in conformance with this policy.

Mission of the Human Factors Branch

The mission of the Human Factors Branch at the AFFTC is to study the design and functional characteristics of aircraft weapon systems as related to human capabilities; to evaluate the man-machine relationship; and to recommend appropriate changes. The Human Factors Branch is a part of the Flight Test Engineering Division. This is one of the four divisions of the Directorate of Flight Test, the others being Flight Test Operations Division, Technical Services Division, and Technical Facilities Division. The Technical Services Division includes the Power Plant Branch, Armament Branch, Photography Branch, and the Experimental Track Branch. The Technical Facilities Division includes the Instrumentation Branch, Data Reduction Branch, Telemetering Branch, and the Space Positioning Branch.

Air Force human factors personnel participate with contractor human factors groups and preliminary design engineers during planning and preliminary design of a weapon system or research vehicle. Recommendations for changing features of the system which affect the human operator are submitted at this early stage of development whenever or wherever practicable. Air Force and contractor personnel maintain close liaison with each other during this stage of development. It is of interest to note that prior to an aircraft's first flight and subsequent entry into the formal U. S. A. F. test program many inspections are accomplished. Experts in the field of power plants, airframes, fuels, oxygen, hydraulics, electronics, armament, cockpit layout, escape systems, and others all attend these formal inspections. At these meetings written requests for alterations (RFA) are tied to the various components which are in need of modification. All these items are discussed and categorized, and eventually the first model or prototype is flown. In spite of all this prior effort, a new series of "squawks" or deficiencies become evident as soon as the aircraft begins to fly.

During phase 2, 4, and 6 testing, human factors project officers are a part of the project control team at Edwards Air Force Base. They work in close cooperation with project engineers of the Flight Test Engineering Division and with project pilots of the Flight Test Operations Division. They depend to a large extent on pilot comments for single-place aircraft and pilot comments plus flight participation in multiplace aircraft. The human factors officers examine and study all human factors problems in the weapon system appearing during phase testing. The following areas are examined: armament, auxiliary equipment, controls, communication, crew welfare and comfort, emergency escape, emergency systems, environment, human performance, instruments and indicators, lighting, maintenance problems, mobility, noise, oxygen system, personal equipment and aircraft compatibility, pressurization system, pressure suits and allied equipment, psychological factors, safety, seating configuration, training, and visibility.

Human factors comments become an integral part of the technical reports that are published at the conclusion of phases 2, 4, and 6. The technical report completely describes the operational characteristics of the aircraft, lists discrepancies, and includes recommended modifications for improvement of unsatisfactory systems.

ARDC Manual 80-1, the Handbook of Instructions for Aircraft Designers (HIAD), is used as a guide by the contractors in designing and equipping a new aircraft that enters the test inventory. This periodically revised document was originally issued in July, 1955. The instructions in the HIAD are of a general nature, and the contractors are permitted a certain freedom in complying with these instructions. The HIAD has references to military specifications for detailed descriptions of special installations. Most of the recommendations submitted by the Human Factors Branch concern details of installation, operation, or maintenance, which are improvements of a contractor's installation from a crew member's operational viewpoint.

There are exceptions to this optimal situation in the procurement of aircraft. One outstanding example is the KC-135 procurement without ejection seats even though the HIAD requires them. The KC-135 is the Air Force fuel-carrying version of the

This will correspond to phases 4, 5, and 6. 3. System operational evaluation. This will correspond to phases 7 and 8. Pending formal publication of the revised regulation, all commands are directed to cooperate in initiating action for execution of test programs on new systems in conformance with this policy.

Mission of the Human Factors Branch

The mission of the Human Factors Branch at the AFFTC is to study the design and functional characteristics of aircraft weapon systems as related to human capabilities; to evaluate the man-machine relationship; and to recommend appropriate changes. The Human Factors Branch is a part of the Flight Test Engineering Division. This is one of the four divisions of the Directorate of Flight Test, the others being Flight Test Operations Division, Technical Services Division, and Technical Facilities Division. The Technical Services Division includes the Power Plant Branch, Armament Branch, Photography Branch, and the Experimental Track Branch. The Technical Facilities Division includes the Instrumentation Branch, Data Reduction Branch, Telemetering Branch, and the Space Positioning Branch.

Air Force human factors personnel participate with contractor human factors groups and preliminary design engineers during planning and preliminary design of a weapon system or research vehicle. Recommendations for changing features of the system which affect the human operator are submitted at this early stage of development whenever or wherever practicable. Air Force and contractor personnel maintain close liaison with each other during this stage of development. It is of interest to note that prior to an aircraft's first flight and subsequent entry into the formal U. S. A. F. test program many inspections are accomplished. Experts in the field of power plants, airframes, fuels, oxygen, hydraulics, electronics, armament, cockpit layout, escape systems, and others all attend these formal inspections. At these meetings written requests for alterations (RFA) are tied to the various components which are in need of modification. All these items are discussed and categorized, and eventually the first model or prototype is flown. In spite of all this prior effort, a new series of "squawks" or deficiencies become evident as soon as the aircraft begins to fly.

During phase 2, 4, and 6 testing, human factors project officers are a part of the project control team at Edwards Air Force Base. They work in close cooperation with project engineers of the Flight Test Engineering Division and with project pilots of the Flight Test Operations Division. They depend to a large extent on pilot comments for single-place air*craft and pilot comments plus flight participation in* multiplace aircraft. The human factors officers examine and study all human factors problems in the weapon system appearing during phase testing. The following areas are examined: armament, auxiliary equipment, controls, communication, crew welfare and comfort, emergency escape, emergency systems, environment, human performance, instruments and indicators, lighting, maintenance problems, mobility, noise, oxygen system, personal equipment and aircraft compatibility, pressurization system, pressure suits and allied equipment, psychological factors, safety, seating configuration, training, and visibility.

Human factors comments become an integral part of the technical reports that are published at the conclusion of phases 2, 4, and 6. The technical report completely describes the operational characteristics of the aircraft, lists discrepancies, and includes recommended modifications for improvement of unsatisfactory systems.

ARDC Manual 80-1, the Handbook of Instructions for Aircraft Designers (HIAD), is used as a guide by the contractors in designing and equipping a new aircraft that enters the test inventory. This periodically revised document was originally issued in July, 1955. The instructions in the HIAD are of a general nature, and the contractors are permitted a certain freedom in complying with these instructions. The HIAD has references to military specifications for detailed descriptions of special installations. Most of the recommendations submitted by the Human Factors Branch concern details of installation, operation, or maintenance, which are improvements of a contractor's installation from a crew member's operational viewpoint.

There are exceptions to this optimal situation in the procurement of aircraft. One outstanding example is the KC-135 procurement without ejection seats even though the HIAD requires them. The KC-135 is the Air Force fuel-carrying version of the passenger-carrying Boeing 707. In this particular case, the military tanker is not equipped with ejection seats. The requirement of early delivery took precedence over a jet tanker ejection seat development program.

Where appropriate HIAD instructions followed by a contractor are still found to be unsatisfactory from a flight test crew member's viewpoint, a report of the situation is made. After coordination with local technical or factory representatives, project pilot, and project engineer, recommendations are forwarded to the Commander, Wright Air Development Center, Attention WCXH, Wright-Patterson Air Force Base, Ohio, describing the preferable system or installation so that the Handbook of Instructions for Aircraft Designers may be correspondingly altered.

Effects of Recommendations and Reports

It has been gratifying to see newer aircraft appearing at the AFFTC which incorporate the majority of recommendations submitted in previous technical reports. The F-100 series, the F-105, and F-106 are excellent examples of contractor follow-up aimed at making the aircraft easier for the pilot to operate. During the past four to five years the aircraft industry has realized the increasing requirement for human factors effort within their own production capability. Today almost every contractor in the aircraft industry has a human factors or a human engineering staff. These staffs vary in size, commensurate with the production capability of the individual corporation, and are composed of a variety of professional personnel in the fields of physiology, psychology, medicine, engineering, and the basic sciences. The Edwards Air Force Base Human Factors Branch is of a similar organization. It is gratifying to realize that there is a large human engineering work force-in-being dedicated to tailoring an aircraft to suit the human operator. Everyone concerned with instrumenting, equipping, and modifying cockpit arrangements of piloted aircraft has realized the necessity of relieving the crew member of as many details of aircraft operation as possible, if missions are to be successful. To evaluate our own ability to identify potential problem areas in test aircraft, personnel of the Human Factors Branch visit the using agencies and discuss current operational problems. By means of a questionnaire and informal pilot interviews, a comparison can be made between problems appearing during flight test evaluation and subsequent tactical employment. To date, this has been done on the F-100C, F-101A, F-102A, and C-133A. Results indicate a reliable identification of problem areas during the flight test program. In the maintenance field, a survey of the fire control, engine, electrical, and weapons repairmen was made at Bergstrom Air Force Base, where the F-101A is being flown operationally. All maintenance personnel were asked to rate their particular system numerically regarding accessibility, simplicity, adequacy of tools, reliability of components and adequacy of ground handling equipment. When these numerical ratings were compared with similar maintenance ratings performance at Edwards Air Force Base while the aircraft was under flight test evaluation, a very close correlation was observed. This would indicate a reliable means of identifying maintenance problem areas which using commands would necessarily want covered by additional training. In some instances unanticipated problems occur in tactical employment because of newer equipment supplied for production of aircraft previously unavailable during the earlier flight test evaluation. A typical example of this is a newer oxygen system supplied for production of F-102A aircraft. This particular oxygen system was not available during the flight test program of the F-102A aircraft.

Aeronautical Medical Support Mission

An interesting aeronautical medical support mission presents itself in the field of research aircraft. For approximately 10 years, aeronautical engineers have been recording in-flight data from instrumented aircraft on ground read-out indicators through telemetry. In the past, when a research aircraft arrived at its flight phase of development and was put in flight, the pilot's physiological status was never recorded during flight. This was the situation during the X-2 program. During the flight phase of the X-15 aircraft, physiological data will be telemetered so that a flight surgeon observing the ground read-out can tell when the pilot is approaching the limit of his physiological tolerance. This will quantitatively identify the most stressful portion of a particular mission profile.

The full pressure suits to be worn during the X-15 program were specifically designed with 12 electrical contact points to facilitate the necessary connections between the telemetering sensers and transmitters.

With current techniques of closed-loop dynamic simulation, it is now possible to record additional physiological data during simulated flight trajectories. During the dynamic simulation at the Naval Air Development Center, Aviation Medical Acceleration Laboratory, Johnsville, Pa., electrocardiographic data were recorded but not telemetered.

Before the first flight date of the X-15 in 1959, pilots' physiological data will be telemetered to ground recording stations to evaluate and prove this technique, with use of a TF-102 which has been specifically assigned the Air Force Flight Test Center for this project. Physiological data will be recorded at Edwards Air Force Base, Calif., by means of currently operational National Advisory Committee for Aeronautics High-Speed Flight Station and U. S. A. F. telemetering receivers.

Items such as (1) cockpit pressure, suit pressure differential, (2) helmet pressure, suit pressure differential, (3) pilot's body surface temperature, and (4) electrocardiographic data will be monitored by a flight surgeon at the ground receiving station during flight. The body surface temperature will be correlated with recorded cockpit temperature. This is an extension of the electrocardiographic recording system monitored by a physician during the centrifuge simulation program at the Naval Air Development Center at Johnsville, Pa. This system has a growth potential for additional data recording and is currently being developed by the contractor. For certain missions, specific data can be collected, permitting a flexibility of operation. The objectives of the TF-102 program at the Air Force Flight Test Center are (1) training and familiarization for X-15 pilots; (2) physiological instrumentation research and development and establishment of criteria for future crew selection; (3) standardization of MC-2 suits; (4) product improvement of MC-2 suit assembly for future weapon systems; and (5) operational capability of the MC-2 suit. To date, approximately 10 hours of actual flight time has been accumulated on the MC-2 suit assembly. The transducers for these measurements are all miniaturized and will not hinder pilot performance in any way. The flat electrocardiographic pick-ups, for example, are approximately the size of small dental x-ray films about 1.25 in. square.

Another interesting aspect of physiological monitoring of pilots associated with the X-15 program is the whole-body radiation level. The University of California operates a whole-body radiation counter for the Los Alamos Scientific Laboratory about 70 miles north of Albuquerque, N. Mex., in the Los Alamos airspace prohibited area. This device is shielded by 20 tons of lead and has been used as an investigative tool in measuring whole-body radiation levels of over 3,000 persons. This gamma counter measures radioactive potassium (K^{40}), a constituent of muscle tissue, and identifies radioactivity as so many counts per second. Preflight base-line K^{40} activity will be obtained from pilots in this program and later correlated with postflight levels. The anticipated increased activity represents a quantitative increment of cosmic radiation effects which will be available for the first time from a human subject flying a research aircraft. This program, with use of the only known whole-body radiation counter, is easy to implement. The only portion that needs to be hurried is the trip back to Los Alamos Scientific Laboratory after landing from a high altitude flight. Since the induced whole-body radioactivity of K^{40} has a half-life of 12.8 hours, the pilot's postflight radioactivity therefore returns to normal in about three days. The technique of performing the whole-body count is very simple, requiring only three minutes, and does not involve the use of drugs. The Los Alamos Scientific Laboratory will obtain a newer whole-body radiation counter for transportation to and installation at the Air Force Flight Test Center.

The Air Force Cambridge Research Center, on inquiry, has expressed a position of interest and complete cooperation regarding assistance in obtaining quantitative data of cosmic-ray activity on the surface of the X-15 itself. These results, compared with the pilot's whole-body radiation activity, should be extremely informative regarding the relation between pilot and aircraft exposure to cosmic-ray activity. The initial proposals include (1) an abrasion detector to measure crater erosion, (2) cosmic radiation by emulsion, and (3) micrometeorite detection.

This, briefly, is the Human Factors or Aero Medical support program for the X-15. The over-all objectives are to obtain quantitative physiological data and to make the pilot's actual flight task a realistic continuation of previous experience and training. The procedures for accomplishing these goals are in existence today; they need only further refinement in an operational aircraft to make their use a reality when the X-15 begins its scheduled flight program.

Conclusions

In closing I think it appropriate to quote from the Handbook of Instructions for Aircraft Designers:

> Investigations in aviation medicine have shown the importance of human capabilities and limitations in aircraft design. Investigations in aviation medicine have augmented knowledge and continue to disclose supplementary data on the physiological and psychological limitations of the human system. As aircraft become more complex, and as their performance characteristics make greater demands on the physical and mental capabilities of the crew, the designer must recognize and cater to these definite limits lest the best conceived aircraft make inordinate demands on the flyer from mechanical, aerodynamic, or tactical standpoints. Further, although the aircraft may operate within the range of human capabilities, a lack of proper consideration for the flyer's comfort and safety, and therefore his efficiency, will result in unwarranted reduction in the effectiveness of the aircraft. Attention to crew safety, comfort, and efficiency at early stages in the design of an aircraft often results in satisfactory provisions with little or no performance penalty.

As members of the Air Force flight test team, those of us engaged in human factors efforts feel that we are contributing to safety, comfort, and efficiency of future manned weapon system and manned research aircraft.

MEDICAL CONSIDERATIONS OF EXPOSURE TO MICROWAVES (RADAR)

Charles I. Barron, M.D.
and
Albert A. Baraff, M.D., Burbank, Calif.

Apprehension over the possibility of injury to man by microwaves is based largely on the fact that sufficiently intense and prolonged radiation of this frequency has caused severe injuries to experimental animals. Several hundred workers who have been occupied about radar installations or have been exposed to radar beams have therefore been observed in a comprehensive medical surveillance program. This has been in progress for four years. The initial study was a comparison of 88 nonexposed persons with 226 radar-exposed employees, some of whom had worked with radar as long as 13 years. No acute, transient, or cumulative physiological or pathological changes attributable to microwaves have been revealed by this study in people working with high-power radar transmitters and frequently exposed to their output. These subjects are free to heed the warning sensation of heat and are advised to avoid exposure to any firing beam when in a zone defined by a minimum power density of 0.0131 watts per square centimeter. Since the development of increasingly high-powered transmitters is to be anticipated, the need for more precise and refined statements of human tolerance is evident.

Considerable interest in the biological aspects of exposure to radar beams has been generated during the past year by widespread publicity of an alleged case of human death occurring after a brief exposure to an unknown quantum of microwaves.[1] The incident served to direct attention to this relatively new agent, and questions naturally arose concerning the extent of the hazard, if any, to persons working with radar transmitters and to those who might be exposed in some manner to the energized beam. Many of these questions have subsequently been answered, and much needed research is being conducted by military and civilian agencies to more closely explore the multifaceted disciplines associated with this complex problem. Unfortunately, these less sensational but more scientifically conducted efforts have received little recognition or dissemination beyond the scientific world.

It is not generally known that apprehension over the biological potentials of microwaves dates back to the early days of World War II, when Daily[2] performed his original studies on U. S. Navy personnel engaged in the operation and testing of relatively low-powered radars. Although this study revealed no evidence of radar-induced pathology in human beings, numerous reports have since appeared indicating that tissue injury and animal death can occur under certain experimental conditions. These studies indicate that cataracts, corneal opacities, testicular degeneration, and hemorrhagic phenomena have been induced in anesthetized, small, furry, test animals by exposure to microwaves in the frequency range of 2,800 to 9,000 megacycles for various time exposures. Boysen,[3] using a transmitter with a frequency of 300 megacycles, exposed rabbits in a wave guide and produced damage to the central nervous system, degenerative changes in the kidneys, heart, liver, and gastrointestinal tract, and hemorrhagic changes in the respiratory tree. The power density measured in the wave guide was in excess of 0.1 watts per square centimeter. The animals were exposed for periods of 7 to 10 minutes, and all whose rectal temperatures exceeded 44.5 C (112.1 F) died. Boysen was of the opinion that the pathology and death were causally related to the hyperthermia.

Because of these rather startling findings and the apprehension engendered by their publication in scientific journals, the medical department of the airframe manufacturer, Lockheed Aircraft Corporation, coincidentally installing, testing, and servicing the most powerful airborne transmitters, early in 1954 instituted a comprehensive medical surveillance program for its several hundred employees working with radar or those who might be exposed to the energized beam. This program has now been in progress for four years and constitutes one of the longest continuous medical surveys of radar-exposed personnel in the United States. It is because of this that we believe the results of our efforts and observations should be presented.

It is not our intent to discuss either the physics of microwave propagation or its ignition hazards. This presentation will be limited to a brief discussion of the objectives, methodology, findings, and interpretation of our program.

From the Medical Department, Lockheed Aircraft Corporation.

Read before the Joint Meeting of the Section on Preventive Medicine and the Aero Medical Association at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

Our objectives were threefold: (1) to detect any cumulative biological effects of long-time exposure to microwaves of varying frequency and power output in persons who had taken minimal precautions; (2) to observe possible effects on persons working for short periods of time with or near extremely high-powered airborne radar with pulsed wave emissions; and (3) to establish correlation between objective findings and units of exposure expressed in time-power density factors with the highly idealized objective of establishing safe maximum exposure standards.

Effects of Long Periods of Exposure

Our initial study included 226 radar-exposed employees and 88 nonexposed control subjects. The examination program was designed to detect in our subjects pathology similar to that observed in exposed animals and included procedures and laboratory studies previously performed by other investigators. Several additional procedures were used in an attempt to duplicate findings alleged to have been observed in a study of human subjects.

Examination in every case included an extensive system and organ inventory, with emphasis on the ocular structures, central nervous system, gastrointestinal and urinary tracts, hematopoietic system, and skin. Imbedded metallic foreign bodies were identified; a careful marital and fertility history was elicited; and duration and manner of exposure to radar was identified.

Physical examination was extensive with respect to the body systems as outlined above. In addition, each subject was inspected for manifest hemorrhagic phenomena. A modified test for Rumpel-Leede phenomenon was then performed by means of placing the blood pressure cuff on the arm and maintaining pressure midway between systolic and diastolic pressure for three minutes. The appearance of more than 10 fresh petechiae in a circle 4 cm. in diameter below the cuff was considered a positive result.

The second phase consisted of an ocular examination, including a slit-lamp study performed with the subject subjected to cycloplegia by a competent ophthalmologist; complete blood cell and platelet counts; chest x-rays; and urinalyses.

Among the radar groups were 83 with 2 to 5 years of exposure and 37 with 5 to 13 years. Many of them were exposed while in military service or with other companies prior to their employment at Lockheed. Few had observed any precautions whatsoever prior to 1953. Despite this, no pathology or adverse physiological effects unequivocally attributable to microwave exposure could be demonstrated. Minor variations in the red and white blood cell counts were comparable with those of the controls. An apparent decrease in polymorphonuclear cells and increase in eosinophils and monocytes was later found to be due to a variation of interpretation by a laboratory technician. There were no significant variations in blood platelet counts. Abnormal urinalyses were found to be proportionate in both groups.

Physical abnormalities revealed a higher percentage of circulatory and gastrointestinal diseases in the controls, with a higher incidence of jaundice, severe headaches, and bleeding phenomena. Ocular pathology was considerably greater in the radar group. However, with the single exception of a small, solitary retinal hemorrhage, which absorbed completely within three months, all abnormalities were causally related to diseases or conditions not generally associated with microwave exposure. Chest x-rays were noncontributory. Modified tests for Rumpel-Leede phenomenon were interesting in that 8% of the control group showed positive results, compared to 2% of the radar group. There was no apparent correlation between positive findings and reduced platelet counts. Findings were negative in all but one subject with platelet counts below 200,000 per cubic millimeter. The positive results were, with this single exception, in persons with normal platelet counts.

Fertility studies revealed essentially the same percentage of offspring in both groups, when correcting for the larger number of unmarried men in the radar group. The percentage of childless marriages attributable to unknown causes was comparable, and in not a single instance in the radar group could an admission of male sterility be elicited.

On the basis of these findings we concluded that no person in this study had sustained any acute or chronic injury secondary to radar exposure. Reference is made to an earlier report describing our results in greater detail.[4]

Effects of Short Periods of Exposure

The second objective of our program is currently being accomplished. Having established base-line or reference criteria, we proceeded to reexamine our personnel, first at 6-month, then at 12-month, and finally at 24-month intervals, approximately four years after the original study. This latter program is now in progress. As a result of our original study and findings it was decided to modify our procedures and eliminate several of the more costly, time-consuming, and noncontributory tests. An extensive medical questionnaire was prepared, and each subject was interviewed by a physician. Physical examinations were performed only when indicated on the basis of the medical history or laboratory studies. Ocular and slit-lamp studies were repeated, and complete blood cell counts and urinalyses were performed. Blood platelet studies were repeated on alternate years. A limited number of electrophoretic serum protein patterns were made in an attempt to validate significant changes claimed to have been observed by another investigator.

Routine control studies were discontinued during the second and third examinations but were resumed in a limited degree during the present program. Despite a small sampling of radar-exposed personnel to date (49) it is believed that this group, under surveillance for four years and with exposure to identifiable transmitters, will provide valuable information for comparative purposes. Additional information obtained includes number of days of sick leave, leaves of absence, and other health statistics for the year 1957. Also, a large number of tests for Rumpel-Leede phenomenon were performed on applicants for employment and employees seeking treatment for routine ailments. None of these subjects had had any known exposure to radar emanations.

TABLE 1.—*Subjects in Medical Surveillance Program*

	Exposed Personnel by Study Group, No.					
Age, Yr.	Single Test	1-Yr.	2-Yr.	4-Yr.	Total	Controls, No.
<20	1	0	0	0	1	0
20-29	62	15	30	5	112	12
30-39	46	24	55	24	149	52
40-49	14	8	22	16	60	30
50-58	5	1	3	4	13	6
Total	128	48	110	49	335	100

The results of our studies are graphically presented in the accompanying tables. Table 1 identifies radar-exposed personnel as to numbers, age group, and years under medical surveillance and compares them to the control group. The total exposure group has increased to 335 by the addition of newly hired or reclassified employees. Persons in the one-year study generally have had two examinations, in the two-year study two or three examinations, and in the four-year study three or four examinations. Only the results of the last examinations are included in subsequent tables.

TABLE 2.—*Fertility Data for Subjects in Medical Surveillance Program*

	Exposed Personnel by Study Group							Controls		
	Single Test	1-Yr.	2-Yr.	4-Yr.	Total	Av. No. of Children	% Without Children	Total	Av. No. of Children	% Without Children
Children, no.	112	36	158	76	382	1.94	...	152	2.11	...
Fathers, no.	72	18	77	30	197	...	...	72	...	...
No children										
Cause known,* no.	40	14	25	17	96	...	27	...	...	10
Cause unknown, no.	16	16	8	2	42	...	13	...	...	18
Total	128	48	110	49	335					

* Major known causes: unmarried, wife sterile, birth control.

Table 2 reveals the fertility history of the radar-exposed and control groups. The slightly lower percentage in the first group who have fathered children is reflected in the larger number of unmarried men in this younger age group. Of those who are married and for unknown reasons have no offspring, the control group shows a somewhat higher percentage. The average number of children per family for each group is approximately two.

Table 3 lists comparative pathology or major subjective complaints for the various groups. These conditions were present at the time of the last examination or had been present the previous year. Among the radar-exposed group, sinus, gastrointestinal, genitourinary, and dermatological complaints were most prevalent. Headaches and nervousness were the commonest subjective complaints. The control group exhibited sinus, allergic, gastrointestinal, joint, and genitourinary disease prevalence, with fewer headaches and skin and respiratory complaints. There were no marked deviations or trends from the common disorders and no unusual or unexplained hemorrhagic phenomena. Bleeding was primarily nasal, rectal, or urinary in origin, and generally of known causation.

TABLE 3.—*Comparative Pathology and Number of Subjects with Major Complaints in Medical Surveillance Program*

	Exposed Personnel by Study Group (335)					
Pathology	Single Test	1-Yr.	2-Yr.	4-Yr.	Total	Controls (100)
Nervousness	4	1	2	3	10	4

Other	2*	1†	...	1‡	4	3§

* Mumps, deafness.
† Diabetes.
‡ Ruptured appendix with peritonitis (subject died).
§ Diabetes, hypothyroidism, hernia.

Table 4 reveals ocular findings for the radar-exposed groups only. In our opinion not a single finding can be attributable to radar exposure. There were no cataracts characteristic of those experimentally induced in animals by hyperthermia, and the corneal scars were, in the main, associated with other known causative agents. There were no tendencies toward progressive ocular diseases, and the four-year group revealed no pathology significantly different from that of the other groups. Congenital sutural cataracts are commonly seen in the general populace and are of no significance.

Sick leave for the 49 subjects who were in the four-year group averaged 3.0 days for the year 1957, compared to 3.1 days for the entire factory. In addition, there were five absences of more than 30 days in the radar-exposed group for the following reasons: hemorrhoidectomy, herniorrhaphy, appendectomy, nervous breakdown, and skull fracture. These longer absences represent a rate of 10% for this small group, compared to a plant-wide rate of 8%. One death occurred among the radar-exposed group; it was attributable to complications after a ruptured appendix. The diagnosis was confirmed on autopsy, and the pathological findings were typical of the disease process. Coincidentally, there were over 200 appendectomies, for acute appendicitis, performed on company personnel during the past year. In 1957 there were 113 deaths of company employees, including several cases of leukemia and plasma cell (multiple) myeloma. There was no known exposure to microwaves in any of these cases.

Table 4.—*Number of Ocular Findings in Radar-Exposed Groups*

Pathology	Single Test (128)	1-Yr. (48)	2-Yr. (110)	4-Yr (49)	Total (335)
Pterygium	1	1	2	1	5
Esotropia or exotropia	5	2	3	3	13
Cornea					
Old scars	4	1	4	1	10
Keratitis bullosa	1	...	...	...	1
Lens					
Cataract, sutural (congenital)	6	2	9	2	19
Cataract, traumatic	1	1	1	...	3
Vitreous "floaters"	1	1	1	1	4
Drüsen	4	...	3	...	7
Other*	6	4	3	4	17

* Papilloma, acute trauma, telangiectasis, blepharitis; leukoma (2), episcleritis, pigment change in iris, allergic conjunctivitis; eclipse burn of macula, small retinal hemorrhage, medullated nerve fibers (3), macular scar (cause unknown); diabetic retinopathy, healed chorioretinitis, surgical ophthalmosteresis.

Table 5 reveals blood findings in the radar-exposed groups and in the 100 control subjects. Only the last blood cell counts for the radar group are shown. It is apparent that the blood picture of the radar-exposed and control groups is comparable in most respects. An unusually high incidence of increased monocytes and eosinophils is noted. However, it is somewhat higher in the control group, and the relative increase in these cells can be traced to the interpretation of one laboratory technician.

Blood platelet determinations revealed counts of less than 200,000 per cubic millimeter in only 2 of 243 subjects tested, despite a higher incidence of reduced counts in our original study. Of the 49 subjects studied over four years, only one had a reduced count. This was unusually revealing, in view of the attempts of at least one investigator to use this as an index of exposure. Also, since the same investigator associated exposure with positive findings on tests for Rumpel-Leede phenomenon, we decided to perform these tests on persons who routinely came to the attention of our medical department. Accordingly, 145 tests were performed on employees seeking minor first-aid care, management personnel undergoing annual health examinations, and a small number of applicants for employment. No subject was included in this study if he had knowingly been exposed to microwaves during military service or employment. Of the 20 positive findings obtained, 14 were in men and 6 in women; these represented 14% of the group. Of these subjects, two presented histories of hemorrhagic tendencies, two had been exposed to considerable ionizing radiation (x-ray), three had undergone recent major abdominal or pelvic surgery, and one was taking sedative medication. Of the 88 subjects used in our original control group (in 1954), positive results were noted in 8%.

In 26 cases selected at random, electrophoresis of serum proteins was performed at a hospital laboratory. Many of these specimens were from subjects in the two-year and four-year groups. Results in 16 tests were reported within normal range for all component proteins; 10 revealed deviations as follows: elevation of gamma globulin level, 4; depression of beta globulin level, 3; elevation of beta globulin level, 1; depression of gamma globulin level, 1; and depression of alpha globulin level, 1. In only one subject was the deviation more than slight or considered significant, and this was partially reversed within two months after elimination of an active known infection. Deviations described are generally associated with dietary deficiencies, infections, or obesity. One subject had been exposed to ionizing radiation, two had known active infections, and two had undergone recent surgery.

In no case was there any significant decrease in serum albumin or total protein levels. The albumin-globulin ratio was within normal limits in all persons.

Maximum Exposure Standards

Our third objective was to delineate safe maximum exposure standards. Obviously, this was contingent on the detection of pathological changes in our subjects and determination of the exposure parameters with respect to frequency or wave length, field power density, exposure time, and total test environment.

Table 5.—*Comparative Blood Cellular Findings in Subjects in Medical Surveillance Program*

	Exposed Personnel by Study Group, No.						Controls	
	Single Test	1-Yr.	2-Yr.	4-Yr.	Total	% of 335	Total	% of 100
Red blood cell count, per cu. mm.								
<4,500,000	...	9	1	1	11	3.3	0	0
4,500,000-5,000,000	20	9	11	2	42	12.5	10	10
White blood cell count, per cu. mm.								
Total								
< 5,000	...	...	...	...	0	0	0	0
>10,000	18	7	21	11	57	17.0	16	16
Differential count								
Polymorphonuclear cells								
<55%	24	4	15	16	59	17.0	19	19
>70%	18	3	14	3	38	11.3	12	12
Monocytes (>6%)	13	10	10	18	51	15.4	21	21
Eosinophils (>4%)	16	4	12	16	48	14.3	16	16

It soon became apparent that this objective could not be achieved in our study. We uncovered no pathology caused by either single or repeated exposure, and consequently we cannot speak authoritatively of so-called hazardous exposure conditions. The majority of our personnel had been exposed to radars of the following types: AN/APS-20A, B, C, and E; AN/APS-28, 30, 31, 33, and 45; AN/APG-40, SG, SX, and SR; AN/APS-6 and 7; and AN/APS 70. These transmitters operate in a frequency range of 400 to 9,000 mc and include powerful "S" band components. It was impossible to obtain precise data covering exposure time and average field power density, since these often were unknown. Exposure, however, varied from an occasional incidental contact with the beam to as much as four hours daily close exposure for periods up to four years. Exposures of several minutes a day at distances of less than 10 ft. from the radars were not uncommon.

Protective clothing was not worn by any of our subjects while in the radar beam. For some time precautions have been exercised in testing of our equipment and in exposure of personnel. In general, ground testing of high-powered, aircraft-mounted transmitters involves scanning of a very limited sector, with the antenna pointed toward an open, uninhabited field and rotating at 2 or 6 rpm, usually firing at reduced power.

Personnel were advised to avoid exposure to any firing beam when in a zone defined by a minimum power density of 0.0131 watts per square centimeter. A second zone, extending from the area previously defined to that with a minimum power density of 0.0039 watts per square centimeter, was deemed acceptable for occasional pass-through but no constant exposure, and, finally, there was a third limitless zone in which exposure was not deemed biologically significant.

Unfortunately, because most persons are exposed to radar emanations while on the ground and frequently within the so-called near radar field, it is extremely difficult to evaluate biological effects and hazards in relation to absolute power levels without accurate measurements. The need for such accuracy in quantitative determinations of exposure is obvious and can be achieved by the development of exposure meters reflecting absorption in quantum units of radar energy.

It has been suggested that the sensation of heat is almost universal on exposure to radar and that this in itself is indicative of an overexposure. In our study, only 17% of the 335 subjects experienced heat sensation and frequently only when in close proximity to "X" band radars. Almost 6% were aware of a buzzing or pulsating sensation when in an "S" band field. Less than 1% experienced other sensations or warning phenomena, such as sparking between dental fillings or a peculiar metallic taste. Eight subjects gave a history of metallic implants, such as bullets, buckshot, steel pins, and plates. None experienced any unusual reaction attributable to the metal. There were no complaints of heat directed to rings, wrist watches, or bracelets.

Comment

During the past 18 years thousands of persons, in the course of their employment or while in military service, have been exposed to microwaves, many without protection. Concern over the effects of such exposure is natural and to be expected. The majority of radars in common use today are relatively low powered, with the exception of some military transmitters which exceed one megawatt in peak power output. Radars with many times this power will be operational in due course and may radically change our entire concept of the biological potentials of this form of energy.

Since microwaves of varying frequency and power output are also being used to provide television display, for diathermy, and in electronic ovens, the personal safety problem is one of general public interest.

Experiments to date have been conducted primarily on small fur-bearing animals and under unusual test conditions. It is generally accepted that the modus of injury by microwaves is a hyperthermia produced by absorption of this form of energy by the body. Extreme caution must be exercised in attempting to extrapolate the results of small animal responses to heat to those of the human body. Small fur-bearing animals have a high coefficient of heat absorption, a small body surface, and a relatively poor heat regulating system. The human body, by comparison, has one of the best and can readily adjust and maintain thermal homeostasis under severe stress conditions. Adequate physiological function can be maintained in environments of 240 F for 23 minutes if the humidity is low, and at least one subject has been exposed to a temperature of 400 F, for a period of approximately one minute, without tissue injury.

Conditions of radar operation and testing vary from experimental conditions. Humans are generally exposed while in free air and rarely to a stationary energized beam. Some radar beams are extremely narrow, and only a small portion of the human body is instantaneously exposed. The body can dissipate heat readily to the environment between such exposures. One is reminded of a similar problem associated with exposure of personnel to the thermal effects of ultrasonic energy. In an analogous situation, small fur-bearing animals were destroyed by hyperthermia when placed in a jet engine noise field, yet there is no evidence of any adverse heating effects on man when exposed to the same environment. It has been estimated that it would require many million times the ultrasonic energy of that generated by any current jet engine to produce these effects in human beings.

There is reason to believe that the dramatic effects observed in small animals exposed to whole-body radiation will not be reproduced in larger, live animals under identical test conditions and that the human body will be the most resistant of all. This is not to imply that localized application of heat cannot injure human tissue. We have witnessed one case of accidental 15-second exposure, at a 6-to-10-in. distance, to an "X" band radar of over 100,000 watts in peak power output, with resultant erythema and a sensation of warmth for an hour but with full and uneventful recovery. Unless carefully controlled and operated, microwave diathermy with use of "S" band frequencies can cause local tissue damage.

In our study we have failed to detect any acute, transient, or cumulative physiological or pathological changes in subjects working with and frequently exposed to high-power radar transmitters. It would therefore appear extremely unlikely that there exists a biological hazard to the radar technician observing reasonable precautions or that the general public, exposed to greatly attenuated and intermittent doses of microwaves in the environment, is in any danger of body injury. We can see no causal relationship betwen microwave exposure and any increase in such conditions as coronary heart disease, leukemia, bone and lung cancer, and degenerative diseases of the nervous system.

There is need for additional research to explore the effects on living tissue of extended wave lengths and frequencies of microwaves and transmitters of higher energy, and military research is being directed in this area.[5] Col. G. M. Knauf has reported on the progress of this research at the American Medical Association's Annual Meeting in San Francisco. It is hoped this study will provide the basis for establishment of a realistic safety program acceptable to all scientists.

Finally, a plea is made for deductive rather than inductive research in this difficult field. With the increasing exposure to microwaves in and around the home, as well as in industry, careless and scientifically uncorroborated reports of human injury and death cannot avoid receiving dramatic and widespread dissemination. Such reports should not appear unless sufficient scientific data are included to support the conclusions and unequivocally establish the modus of injury. If radar is incriminated, the report must contain a definite history of exposure, including proper identification of the transmitter, wave length, power density, exposure time, symptomatology, laboratory data, pathological findings, and other factors.

Summary

In 1954, a medical surveillance program was instituted, covering 335 employees working with or exposed to microwaves in an airframe manufacturing company. Examinations have been performed at intervals of 6, 12, and 24 months in an effort to detect acute or cumulative biological effects of exposure at various intervals to energized radar beams in the 400-to-9,000-mc range and with peak power output exceeding one megawatt. Whenever possible, identical examinations were also accomplished on a nonexposed control group.

The examinations have failed to detect any significant changes in the physical inventories of the subjects. The incidence of death and chronic disease, sick leave, and subjective complaints was comparable in both groups. A high percentage of eye pathology was identified, but none with causal relation to the hyperthermia produced by microwave absorption. Fertility studies revealed essentially the same findings for both groups.

Laboratory studies for total red and white blood cell counts and differential counts revealed no significant changes above those noted in the control group. Urinalyses and chest x-rays were noncontributory with respect to radar exposures. Electrophoretic serum protein level determinations were performed on 26 subjects, with insignificant or accountable deviations in 10. Platelet counts and controlled capillary fragility studies for Rumpel-Leede phenomenon revealed the fallacy of using either to identify radar exposure. In addition, only a small percentage of the exposed subjects had been aware of heat or other subjective warning phenomena. Neither these tests nor subjective complaints were considered reliable indexes of exposure.

Absolute or safe maximum exposure standards were impossible to define, inasmuch as no radar-induced pathology could be identified. Subjects had been exposed for various periods, at indefinite distances, to a multitude of radars under flexible test conditions. The need for more precise and refined exposure data is indicated.

On the basis of these studies there appears to be no justification for public concern about the effects of greatly attenuated microwave energy in the environment. It would seem, therefore, that one may continue to enjoy his television without undue apprehension.

SYNCOPE IN A POPULATION OF HEALTHY YOUNG ADULTS

INCIDENCE, MECHANISMS, AND SIGNIFICANCE

Capt. George Dermksian (MC), U. S. A. F.
and
Lawrence E. Lamb, M.D., Randolph Air Force Base, Texas

A better understanding of mechanisms precipitating syncopal episodes and their likelihood of recurrence can lead to prevention of accidents resulting from syncope and perhaps prevent syncopal episodes at crucial times. Eighty-two persons studied described a total of 113 syncopal episodes occurring sometime in the past. The factors, surrounding the acute clinical episode of syncope, were highly variable. More than one factor may have played a role in the precipitation of syncope in a large number of the cases. The overt act at the time of syncope was most often postural change or pain. Cardiac arrhythmias induced by the common respiratory maneuvers were often associated with syncope. Disturbances in a person's general hygiene not only decrease his stress tolerance but apparently make him more susceptible to syncope.

Syncope, or fainting, is a common, everyday occurrence. Both the lay public and the medical profession tend to regard it casually, due to the lack of complications and sequelae. However, in the situational environments of industry and aviation, transitory loss of consciousness may result in serious accidents and death.

In any operation involving a man-machine effort, the success of the operation depends on the man just as much as on the machine. Modern aviation is a good example wherein split-second failure on the part of the man can have disastrous results. In recognition of the importance of syncope as a cause of human failure in aviation, an effort is made to detect those persons who are syncope-prone as a preventive measure and all cases of syncope are carefully studied to ascertain the cause when possible. Among flying personnel, 82 persons who have experienced 113 syncopal episodes have recently been studied at the School of Aviation Medicine.

Method and Techniques

Studies on the 82 apparently healthy persons included the taking of a detailed history, a complete physical examination, blood cell count, determination of hematocrit value, erythrocyte sedimentation rate, and fasting blood sugar level, urinalysis, chest x-ray, skull x-ray, and electrocardiogram. Other tests have been utilized when indicated. In addition to this routine examination, 55 persons were given a battery of special procedures designed to stress the cardiovascular system. In this manner it was hoped to determine the factors which might have contributed to their syncopal episodes and also to study the disturbances in the cardiovascular mechanisms associated with syncope. The patient's blood pressure, pulse rate, symptoms, and signs were observed at rest and on a tilt table during (1) breath-holding at maximum inspiration; (2) hyperventilation followed by breath-holding; and (3) carotid sinus massage of 15 seconds' duration. A 15-minute orthostatic tolerance test on the tilt table and a one-minute cold pressor test (hand immersed in water of a temperature between 0 and 1 C) were performed. The response to intravenously given atropine, 0.75-1.2 mg., was also studied in five cases.

Results

The 82 persons studied in this series were U. S. A. F. flying personnel. They described a total of 113 syncopal episodes occurring sometime in the past. The factors surrounding the acute clinical episode of syncope were highly variable. The age at the time of syncope, a brief note about the clinical circumstances, and the findings during the clinical investigation are briefly summarized in the table. From the brief clinical notes it can be seen that more than one factor may have played a role in the precipitation of syncope in a large number of the cases. The overt act at the time of syncope was most often postural changes or pain. Eleven subjects had recently ingested at least one alcoholic drink prior to the syncopal episode, six had been on weight-reducing diets, and others had recently completed some exhaustive physical labor and/or lacked adequate rest. It is our impression that disturbances in a person's general hygiene not only decrease his stress tolerance but apparently make him more susceptible to syncope.

Only one of the cases could definitely be attributed to a clinical episode of cardiac arrhythmia. This is not surprising, since this was the only episode of clinical syncope monitored by an electrocardiogram.

Read before the Joint Meeting of the Section on Preventive Medi- and the Aero Medical Association at the 107th Annual Meeting the American Medical Association, San Francisco, June 25, 1958.

Clinical Findings in Eighty-two Persons Who Had Experienced Syncope

Case No.	Age at Time of Syncope, Yr.	Clinical Incident Associated with Syncope	Findings on Investigative Procedures
1	31	Venipuncture	Atropine caused shift in pacemaker to atrial focus
2	12	Standing up	Near syncopal episode after release of breath-holding; cardiac rate decreased from 102 to 60/min.
	28	Fatigue, alcohol ingestion, bending over	
3	33	Alcohol ingestion	None
4	25	Standing in one position 3-4 hr.	None
5	23	Alcohol ingestion, warm, smoky room	Had syncope twice when placed on tilt table to obtain base-line blood pressure and electrocardiogram; sinus arrest with each episode and nodal escape beats
	23	Psychic trauma (dog hit by car); alcohol ingestion; warm room	
	24	Standing	
6	23	Urination	Near syncope with marked drop in blood pressure during breath-holding; syncope on breath-holding after hyperventilation; cardiac rate decreased from 110 to 65/min.
7	22	"Influenza"; deep breath	None
8	28	Flying at 31,000 ft.	Cold pressor test caused asystole and near syncopal episode
9	14	Had a "cold"; sitting in warm room	Syncope 2 min. after right carotid massage; heart rate decreased to 30/min. with precipitous fall in blood pressure
	23	Upper respiratory infection; syncope after hyperventilation in altitude chamber	
	24	Standing at attention	
10	25	Had just arisen and was preparing to wash (later proved to have grand mal seizures)	None; EEG normal
11	24	While piloting aircraft, suddenly lost 13,500 ft. of altitude; circumstances unknown; presumably momentary loss of consciousness	Near syncopal episode with marked drop in blood pressure when base-line studies were being recorded on tilt table
12	37	Felt something in his throat and turned to cough; lost consciousness before coughing	None
13	23	Gastroenteritis	None
14	32	Unexplained loss of consciousness while piloting aircraft; suggestion of difficulty with face mask; apparently not hypoxia, as he regained consciousness and made unsuccessful attempt to control aircraft	Breath-holding at height of inspiration resulted in lower nodal rhythm and syncope
15	36	Urination; fatigue; lack of food; alcohol ingestion	None
16	39	After vomiting; history of fatigue	None
17	24	Pain	None
18	29	Sudden loss of 16,000 ft. of altitude while piloting aircraft; apparent transitory loss of consciousness in flight	None
19	37	Topical application of anesthetic to eye for tonometer measurement	Breath-holding after hyperventilation resulted in decrease in heart rate from 135 to 66/min. with syncope
20	26	Standing at attention in sun	Near syncope after left carotid sinus massage. Heart rate slowed from 90 to 66/min.
21	23	While flying at 31,000 ft. turned in seat, became nauseated and dizzy, and lost consciousness	Repeated syncopal episodes after breath-holding, associated with asystole
22	30	Was in warm room, went outside, and either slipped on ice and fell or experienced syncope	None
23	35	Alcohol ingestion; large meal; standing up	None
24	25	Venipuncture	None
25	26	Defecation; gastroenteritis	None
26	35	Exertion; dieting	None
	35	Mowing the lawn; dieting	
27	34	Standing after bending	Breath-holding after hyperventilation was associated with A-V dissociation; no symptoms
28	18	Unexplained syncope while seated playing cards	Syncope when breath-holding at height of inspiration, associated with decrease in blood pressure without significant cardiac arrhythmia
29	22	Flying at 8,000 ft.; patient does not know what happened	None
30	26	Seated after exertion; lack of food and sleep	None
31	25	Pain	None
32	23	Shaving; lack of sleep; sunburn	None
33	25	Hyperventilation at 24,000 ft. in altitude chamber	None
	27	Hyperventilation at 24,000 ft. in altitude chamber	
	30	Walking	
34	23	Seated in classroom listening to lecture on disagreeable subject	None
35	22	Called to attention	Convulsion after left carotid sinus massage reproduced without decrease in heart rate or diminished blood pressure
	22	Convulsion after left carotid sinus massage	
36	27	Standing	Breath-holding demonstrated A-V dissociciation without symptoms
37	25	Standing in line for physical examination; fainted as he walked away from doctor after examination	Syncope after right carotid massage; cardiac rate decreased from 120 to 68/min.
38	28	Seated at table, rose from chair, and fainted; weight reducing; alcohol ingestion	None
39	18	Gastroenteritis	No special studies
	30	Back pain	
	30	Manipulation of back and production of pain (next day)	
40	37	Getting out of bed	No special studies
41	26	Alcohol ingestion	No special studies
42	36	Urination; had been hospitalized for possible myocardial infarction which he did not have; was watching TV program on myocardial infarction prior to acute episode of syncope; was nauseated	No special studies
43	23	Acrobatics and pulling 2½ to 3 G forces	No special studies
44	23	Aircraft let down while in hot cockpit; nauseated	No special studies
45	Childhood	Dental procedure	No special studies
	Childhood	Gastroenteritis	
	Childhood	Pain	
	Childhood	Sight of blood	
	38	Patient's child had nosebleed; patient fainted while assisting him	
	38	Venipuncture (next day)	
46	35	Straining at stool with painful bowel movement	No special studies
47	22	Acrobatics in back seat of aircraft	No special studies
48	40	Repeated near syncopal episodes with dental procedures	No special studies
49	37	Standing at racetrack watching racing cars; had been drinking with inadequate food intake; had previously been on reducing diet	No special studies
50	35	Walking into flight operations; fatigued from lack of sleep and food	None
51	23	Vomiting; became nauseated while listening to lecture on altitude chamber	No special studies
52	26	Fell out of bed and was apparently unconscious	No special studies
53	21	Local treatment of acute external otitis; developed pain and syncope	Nodal rhythm after stimulation of external ear; no other special studies
	21	Repeated syncopal episode with ear manipulation	
54	33	Gastroenteritis with dehydration and poor nutrition	No special studies
55	35	Standing after bending	No special studies
56	38	Hypoxia and hyperventilation in altitude chamber	No special studies

Clinical Findings in Eighty-two Persons Who Had Experienced Syncope—Continued

Case No.	Age at Time of Syncope, Yr.	Clinical Incident Associated with Syncope	Findings on Investigative Procedures
57	4	Hit on head with rock	No special studies
	15	Systemic febrile response to immunization	
	24	Teeth cleaned by dental technician	
58	26	Epigastric pain after eating; took several deep breaths and attempted to belch; syncope resulted	No special studies
59	21	Syncope with G forces; back pain	No special studies
60	23	Standing after extreme exertion	None
	23	Same as above	
61	33	Multiple injuries due to aircraft accident	Breath-holding after hyperventilation caused syncope with decreased blood pressure; during investigation patient developed nodal rhythm with syncope; carotid sinus massage produced bradycardia with near syncope
	35	Pressure breathing in altitude chamber at 43,000 feet; nodal rhythm with seizure	
62	24	Seated; acute gastroenteritis	No special studies
63	30	Pain	No special studies
64	Childhood	Syncope on sight of blood	No special studies
	26	Standing after bending over	
	26	Rapid decompression in altitude chamber; holding breath	
65	20	Standing during fraternity initiation after lack of sleep for 72 hr.	None
	26	Syncope resulting from G force intolerance	
66	27	Syncope on arising rapidly from bed	None
	33	Same as above	
	36	Same as above	
67	38	Pain	No special studies
	38	Manipulation of wound	
68	11	Getting out of bed after febrile illness	No special studies
	15	Standing 3 hr. in crowded room	
69	37	Pain	No special studies
	37	Bending over after exertion	
70	31	Getting out of bed	No special studies
71	27	Breath-holding rather than expiring during rapid decompression in altitude chamber	None
72	31	Sitting during lecture; lack of sleep; alcohol ingestion	None
73	22	Syncope after shower; felt dizzy	None
74	30	Vomiting; had a "cold" headache and had been drinking but denied inebriation	None
75	37	Urination	Syncope after right carotid massage and left carotid massage, with A-V dissociation and nodal rhythm
76	33	Suddenly standing	None
77	37	Starting to shave; lack of sleep; headache; chest pains	None
78	23	Apathetic episode during instrument check in aircraft; described as syncope by instructor	None
79	12	Getting out of bed after pneumonia	None
	20	Near syncope during venipuncture	
80	26	Flying; looking at radarscope	None
81	30	Standing in hospital room visiting son after tonsillectomy	None
	34	Standing at bar; syncopal episode after one drink	
82	21	Had a "cold"; chest being examined by physician; deep breaths	Breath-holding produced depression of SA node and shift to atrial focus followed by A-V dissociation; one episode of marked sinus depression with only one sinus impulse occurring over 6-sec. period; cardioinhibitory response prevented by atropine

Of the 55 subjects examined by the special techniques, 16 had a syncopal or near syncopal episode during the investigative procedures. An additional subject (case 53) had the onset of a nodal rhythm during external ear stimulation which resulted in syncope. This subject was not otherwise examined by the special technique. Of the 17 subjects who developed experimental syncope, in 13 the incident was associated with a cardiac arrhythmia or a marked decrease in cardiac rate. Four persons had syncope with insignificant changes in the cardiac rhythm.

In this series of 55 subjects, 17 developed a cardiac arrhythmia or marked cardioinhibitory response with or without syncope. Breath-holding induced cardiac arrhythmia in nine cases, including three examples of marked sinus bradycardia. In six of the nine cases the arrhythmia was associated with syncope. Breath-holding caused syncope in eight individuals. In one of these it was chiefly a vasodepressor response without significant arrhythmia.

It is interesting to note that 13 of these subjects experienced clinical syncopal episodes during flight. Five instances were attributed to G forces. Of the remaining eight persons, four developed experimental syncope associated with significant cardiac arrhythmias (cases 8, 11, 14, and 21).

Since syncope is regarded so casually by both the lay public and the medical profession, it is difficult to obtain many facts concerning its incidence or much factual information concerning its causes. The clinical histories of these 82 subjects point up the varied and intangible circumstances that might surround any syncopal episode.

Incidence

Very little information is available concerning the expected incidence of syncope in the general population or in various age groups. Guzman-Perry [1] studied 300 healthy young male students at college and postgraduate levels of training. He found a 15.5% incidence of fainting. Collins [2] studied a group of basic trainees in the U.S.A.F. and reported an incidence of 0.8% in applicants and 22.3% in nonapplicants for flying training. He attributed this discrepancy in incidence in two basically similar groups to the withholding of information on the part of the flying applicants, since a history of fainting would disqualify them for flying training.

Since the true incidence of syncope in any population has not been established, 5,000 questionnaires were sent to Air Force personnel. The questionnaires were to be returned unsigned in order to avoid any motivation to withhold information. In this manner it was hoped to obtain an incidence of syncope in an apparently healthy, young adult male population. Of the 5,000 questionnaires sent out, approximately 60% were returned. The age range of this population was 17 to 62 years, with an average age of 29.1 and a mode of 27.2. The reported incidence of true syncope in this study was

7%; loss of consciousness due to a severe blow to the body or head was found in 4% and both in 0.7% of the cases. The incidence of true syncope and loss of consciousness due to severe bodily trauma is broken down for the various age groups and presented in figures 1 and 2. It is recognized that a number of statistical objections could be raised against any such questionnaire survey. Nevertheless, the incidence of syncope in the returned questionnaires is interesting, even though it probably is not an exact incidence figure.

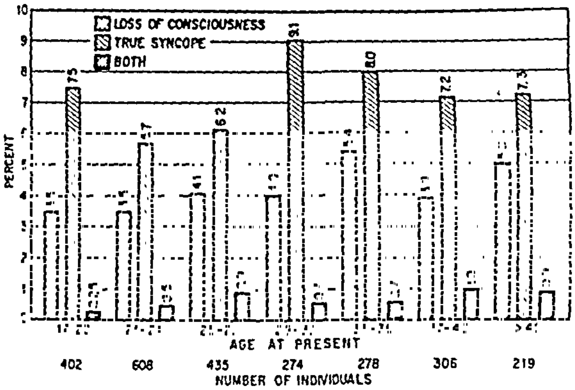

Fig. 1.—Incidence of syncope and loss of consciousness due to severe bodily trauma, by present age.

Mechanisms of Syncope

It is difficult to classify syncope because of the large number of possible underlying disorders and the variability of the acute precipitating factors. Weiss,[3] in 1935, presented a comprehensive study and discussion of syncope and syncope-like episodes. A more recent monograph by Engle[4] discusses the mechanisms and clinical characteristics of various types of loss of consciousness in the light of current physiological and psychological concepts. Many authors have chosen to consider or discuss one specific type of syncope.[5]

We have found the following classification of syncope to be simple and useful. It is based primarily on physiological mechanisms rather than on specific etiologies. Most mechanisms resulting in syncope can be grouped into one of six general categories: (1) venous (inadequate return of blood to the left heart), including systemic and pulmonary; (2) cardiac (ineffective pumping action); (3) loss of arteriolar tone (change in routing of blood flow); (4) blood qualitative changes (abnormalities in the constituents of the circulating blood); (5) blood quantitative changes (inadequate circulating volume); and (6) central nervous system (local disorders). More than one mechanism may be involved in any single episode of syncope, e. g., cardioinhibitory response with arteriolar dilatation.

Deficiencies in Venous Return.—Deficiencies in venous return, both in the systemic and pulmonary circulation, may result in syncope. Large varicosities of the lower extremities may trap blood peripherally, resulting in inadequate venous return, diminished cardiac output, and loss of consciousness. Venous pooling is one of the factors in orthostatic hypotension which contributes to syncope. Pressure breathing and the Valsalva maneuver may also inhibit adequate venous return.

The inspiratory effort at the onset of the Valsalva maneuver creates an increase in the negative intrapleural pressure and results in an initial increase in venous return to the right heart. This, in turn, causes an increased output of the right side of the heart. This increased output is trapped in the overexpanded pulmonary vascular bed, resulting momentarily in diminished venous return to the left side of the heart and diminished output on that side. Bearing down against the closed glottis tends to increase the intraalveolar pressure and squeeze the blood trapped in the lungs into the left side of the heart. The increased intrathoracic pressure inhibits further venous return to the right side of the heart, resulting in inadequate venous return. This is only one of the effects of the Valsalva maneuver. The breath-holding and resultant vagal stimulation may induce a cardioinhibitory response; this will be discussed below.

Other factors which may influence venous return to the left side of the heart include pressure breathing, visceral pooling, changes in venous tone secondary to orthostatic influences, and perhaps, to some extent, G forces. In this series of 82 patients not one example of varicosities could be implicated as contributing to or resulting in a syncopal episode. This would be expected because the subjects were initially selected as a healthy population. In addition, there were no cases which could be attributed solely to venous factors. A combination of venous and arteriolar factors are probably present in most postural or orthostatic adjustments and in tolerance to G forces. The one example of syncope after a Valsalva maneuver in this series may have been due to a deficiency of venous return and/or may have been associated with a cardiac arrhythmia.

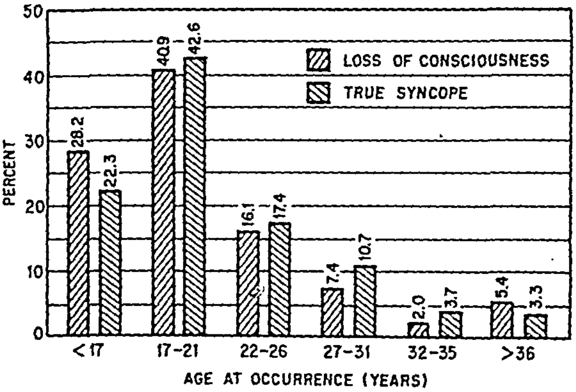

Fig. 2.—Percentage of episodes of syncope and loss of consciousness due to sever body trauma, by age of occurrence.

[illegible] Pumping Action of Heart.—Disturbances of the heart's pumping action may be due to disease of the endocardium, myocardium, or pericardium. In addition, a large variety of arrhythmias may result in syncope. In this healthy young adult male population, one would expect the incidence of syncope secondary to cardiac disease to be quite low, due to the previous screening examinations. None of the clinical syncopal episodes in this series could be attributed to underlying heart disease. Some, however, may have been due to cardiac arrhythmia, but this point can not be proved or disproved without better knowledge of the cardiac rhythm at the time of clinical syncope. In contrast, in evaluating the cardiovascular status of the subjects in this report, it was impressive to note the high incidence of cardiac arrhythmias associated with experimental syncope. By far the majority of these were induced by respiratory maneuvers, i. e., breath-holding or hyperventilation followed by breath-holding. These cardiac arrhythmias were induced in persons whose cardiac status was otherwise normal in all respects. It was also impressive to note that the most common method of inducing experimental syncope in the battery of special tests used was the breathing maneuvers. The majority of the arrhythmias were of the cardioinhibitory type. Two examples of cardiac arrest were noted (up to 12 seconds' duration) after simple breathing maneuvers. It has previously been demonstrated that significant cardiac arrhythmias may be induced by respiratory maneuvers, even with the subject in the recumbent position.[6] This fact argues against the response being solely a postural one.

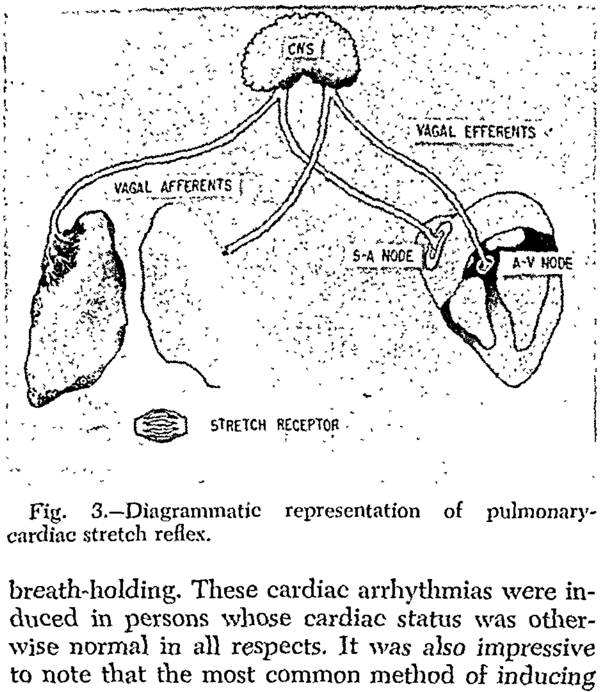

Fig. 3.—Diagrammatic representation of pulmonary-cardiac stretch reflex.

It is thought that the respiratory stimulation of the vagus nerve is the principal means of inducing the cardioinhibitory response in these individuals. The receptors and nerve pathways of such a reflex have been described. It is known as the pulmonary stretch reflex. Stretch receptors are located in the tracheobronchial tree, peripheral pulmonary parenchyma, and the visceral and parietal pleura. The receptors are stimulated by various respiratory maneuvers but primarily by inflation of the lungs. Impulses are carried via vagal visceral afferent fibers to their terminals in the sensory nucleus of the vagus and in the nucleus of the tractus solitarius. At this point their fibers come into relation with the neurons from the respiratory, vasopressor, and vasodepressor centers. Pathways from these centers descend to the spinal cord and also connect to the dorsal motor nucleus of the vagus. The efferent arc of this reflex is mediated via vagal autonomic fibers which arise from the dorsal nucleus as preganglionic fibers and go to the cardiac plexus. Postganglionic inhibitory fibers arise from the plexus and terminate in the sinoatrial and atrioventricular nodes.[7] The right vagus has its primary effect on the sinoatrial node and depresses impulse formation there, while the left vagus decreases the relative refractory period of the atrioventricular node (fig. 3). In most individuals stimulation of the stretch reflex results in varying degrees of cardiac slowing. Maximum slowing of the heart rate usually occurs at the height of the inspiratory effort. The efferent pathway for the pulmonary stretch reflex is the same as the efferent pathway of the carotid sinus reflex. The reflex can similarly be expected to cause a cardioinhibitory and/or a vasodepressor response.

It has been demonstrated that the cardioinhibitory response in susceptible individuals can be abolished by the administration of therapeutic doses of atropine (0.75-1.2 mg.). After adequate administration of atropine, other forms of cardiac arrhythmia induced by respiratory maneuvers could be prevented. In one example impending syncope was terminated by the intravenous administration of 1.2 mg. of atropine.

Atropine has been used by many investigators to induce syncope in subjects on the tilt table by increasing arteriolar and venous pooling.[8] When experimental studies are done in this manner, it is not likely that cardiac arrhythmias will be noted, as atropine will prevent the expected cardioinhibitory response. In this study a high incidence of cardiac arrhythmias was noted because atropine was not administered until after the breathing maneuvers and other stresses were carried out.

The demonstration that cardiac arrhythmias and syncope may be induced by stimulation of the pulmonary stretch reflex has direct application to any occupation, activity, or medical procedure which may involve simple respiratory maneuvers. It is common practice in aviation to use pressure breathing. The susceptible person may have a hyperactive response to stimulation of the pulmonary stretch reflex inducing cardiac asystole and syncope. Hyperventilation is not uncommon on exposure to altitude. The pilot who holds his breath when hyperventilation is noted may stimulate the pulmonary stretch reflex, induce a cardiac arrhythmia, precipitate a syncopal episode, and be listed as having an unexplained aircraft accident. At least three unexplained sudden deaths are known to us which have occurred in persons engaged in breath-holding in underwater swimming or diving.

Artificial respiration in the operating room is an everyday occurrence. The lungs are regularly inflated by the anesthesiologist. Cardiac arrhythmias and, in fact, cardiac arrest are not unknown in the operating room. It is suggested that one of the mechanisms which may induce cardiac arrest at the time of surgery is stimulation of the pulmonary stretch reflex during artificial respiration. Small preoperative doses of atropine (0.4 mg.) are inadequate to abolish the vagal effect of the pulmonary stretch reflex.

It is possible that intermittent postive-pressure breathing, as used on medical wards, may also stimulate this reflex in susceptible individuals and could result in cardiac arrhythmia and syncope.

As is often the case, man discovers empirically methods of protecting himself when exposed to new or strange environments. Early in aviation, it was learned that the Valsalva maneuver could produce syncope. A modification of the Valsalva maneuver, now termed the M1 maneuver, was found to be most useful in increasing G tolerance during flight. In this M1 maneuver, after a deep breath is taken, rather than holding the breath in deep inspiration the person expires forcefully against a partially closed glottis, resulting in a loud yell or scream. Not only may exhaling in this manner immediately after inspiration favorably influence the mechanical factors associated with circulation, but also it abolishes further stimulation of the pulmonary stretch reflex. Thus, a correctly performed M1 maneuver serves to protect against development of significant cardiac arrhythmias which may be induced by the simple Valsalva maneuver.

Loss of Peripheral Arteriolar Resistance.—The third basic mechanism which may result in syncope is a loss of peripheral arteriolar resistance. Pain, alcohol, and true orthostatic hypotension are some examples which may affect arteriolar tone. In addition, everyone is familiar with the sensation of lightheadedness first experienced on arising after having been confined to bed for an acute illness. Any febrile illness may also decrease normal arteriolar tone, as may heat, exhaustion, or fear. Mechanical influences, such as positive G forces, may overcome normal peripheral resistance. Disturbance in arteriolar tone appears to be one of the more frequent mechanisms involved in clinical syncope. Peripheral arteriolar resistance may also be diminished in association with cardioinhibitory responses. In experimental syncope induced in these studies, a number of subjects were noted to have both a marked fall in blood pressure associated with decreased arteriolar tone and cardioinhibitory response with decreased heart rate.

Qualitative Changes in Circulating Blood.—A fourth group of contributing or sole etiological factors in clinical syncope includes qualitative changes in the circulating blood. This includes such factors as toxins, hypoxia, changes in acid-base and electrolyte balance, and anemia. In this series, direct toxins, carbon monoxide, and hypoxia were found to be infrequent causes of syncope despite the fact that all the subjects were flying personnel. True hypoglycemia could not be demonstrated to be the cause of a single episode of syncope. This may be due to the fact that hypoglycemia is more frequently associated with disturbances in mental state rather than true syncope.[9] It is possible that those individuals with relatively low blood sugar levels have a diminished tolerance to stress and are therefore more syncope-prone. When a significant anemia is present, cardiac output is increased and circulation time is decreased. This is a compensatory mechanism to provide adequate oxygenation to the body tissues, including the central nervous system. Under normal circumstances the circulatory system could perhaps adjust to a given stress. When an underlying anemia is present, the circulatory system is already compromised and the same amount of stress is capable of producing syncope.

Quantitative Change in Circulating Blood.—Decreases in the amount of the circulating blood may cause an individual to be more syncope-prone. Acute blood loss is the most obvious cause of decreased circulating blood volume. Dehydration from any cause may also diminish the circulating blood volume. In 7% of the clinical episodes of syncope in this series, dehydration secondary to gastroenteritis was a sole or major contributing factor.

Disorders of Central Nervous System.—Disorders in function of the central nervous system comprise another large group of causes of clinical syncope. This includes hemorrhage, e. g., from berry aneurysm in young persons, cerebral thrombosis, tumor, infection, metabolic changes, convulsive disorders, and other diseases of the brain and spinal cord. During experimental procedures carried out on two of the subjects in this series, it was clearly demonstrated that cardiac arrhythmias producing changes in circulatory dynamics preceded any evidence of central nervous system malfunction. In both cases an electroencephalogram was recorded and showed changes only after significant circulatory abnormalities had occurred.

Since the pulmonary stretch reflex's role in the production of cardiac arrhythmia and syncope is relatively unknown and was the most frequent cause of experimental syncope in this series, two cases illustrating this mechanism are presented.

Report of Cases

Case 21.—A 23-year-old pilot lost consciousness while flying between 31,000 and 37,000 ft. (cabin altitude 10,000-12,000 ft.) in a B-47. The aircraft had been airborne approximately seven hours, and he had been breathing oxygen. While seated, he turned to the right to "shoot the stars" when he noted the onset of nausea and dizziness. The next thing he remembered was someone reaching over him to check his oxygen equipment. He had lost consciousness and slipped to the floor. There were no other associated signs, symptoms, or residuals. The flight was terminated, and one-half hour later the patient was examined by a physician. Physical examination and laboratory studies were unremarkable.

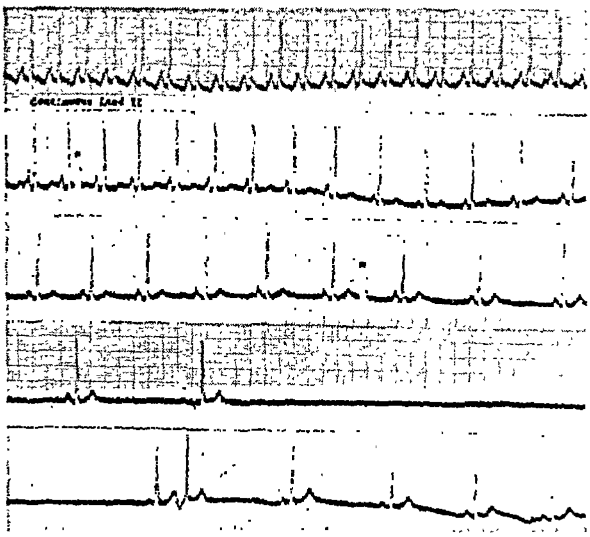

Fig. 4 (case 21).—Continuous recording of standard lead 2 during breath-holding. Nine-second period of asystole was associated with syncope. Episode was terminated by tilting of patient to horizontal position.

Subsequent follow-up and extensive diagnostic studies, including hematology, urinalysis, chest and skull x-rays, determination of blood sugar level, electrocardiogram, and electroencephalogram, were unremarkable. During the special syncope studies, when the patient took a deep breath and held it his cardiac rate slowed from 116 to 100 per minute. With the onset of breath-holding, there were two ventricular premature contractions in bigeminal fashion. The conduction then changed from sinus tachycardia to atrioventricular dissociation. After 27 seconds of breath-holding, the rate suddenly decreased to 60 per minute, and at the 36th second a six-second period of asystole followed by a sinus escape beat occurred. The patient was pale, perspiring, and clammy. After 47 seconds of breath-holding he released his breath and the shift was made to sinus bradycardia with a rate of 48 per minute. His mentation was slow, and he complained of "dizziness." At the 16th second of the recovery period he developed a three-second period of asystole, terminated with one sinus beat and followed by another three-second period of asystole. This was followed by three sinus beats and a 12-second period of asystole. The period of cardiac arrest was terminated by two ventricular impulses. During the period of asystole the patient lost consciousness. He was tilted to the horizontal position, and a normal sinus rhythm reappeared. The patient recovered.

After suitable periods of recovery, essentially the same series of events were reproduced with hyperventilation immediately followed by breath-holding and by breath-holding alone. The only difference was the appearance of nodal escape beats during the periods of asystole. With 0.75 mg. of atropine, the above sequence of events was prevented on two occasions.

Five days after the initial studies, the patient returned for repeated study. Again, whenever the patient held his breath his cardiac rate slowed, changed to atrioventricular dissociation, and then periods of asystole developed which were associated with a disturbance of or actual loss of consciousness (fig. 4). Atropine again prevented the development of arrhythmia and the loss of consciousness on two occasions.

Case 82.—A 21-year-old aviation cadet visited his flight surgeon because of symptoms and signs of an upper respiratory infection. His oral temperature was 101 F (38.3 C). During auscultation of his chest, the patient was asked to breath deeply and then to hold his breath. He apparently began to sway and had to be helped to a chair. The cadet then became flaccid and lost consciousness. Examination of the heart revealed a rate of 48 per minute and an irregular rhythm. Within 10 minutes an electrocardiogram was taken and blood drawn for determination of blood sugar level. These and other studies showed findings within normal limits.

He was hospitalized for four days and treated for his upper respiratory infection. No other abnormalities were noted on extensive physical and laboratory examination. There was no previous history of syncope or seizures.

The patient was referred to the School of Aviation Medicine where physical examination and laboratory studies, including hematology, urinalysis, determination of fasting blood sugar level, routine electrocardiogram, Master's double exercise tolerance test, altitude chamber flight with electrocardiogram, and skull and chest x-rays, were unremarkable. During the special cardiovascular studies, on every occasion that the patient held his breath during inspiration, on or off the tilt table and with and without preceding hyperventilation, his cardiac rate would suddenly slow. There would be a shift in the pacemaker either to another area in the sinoatrial node or to an atrial focus. With continued breath-holding, the pacemaker would revert to the original focus. This shift in pacemaker would occur two or three times during one period of breath-holding.

During one of these periods of breath-holding, while the patient was standing, there was a sudden slowing of the cardiac rate from 118 to 60 per minute. Associated with this, the patient became pale and began to perspire. In the next three seconds, the cardiac rate further slowed, to 40 per minute, and then there was a three-second period of asystole terminated by one normal sinus beat and followed by another three-second period of asystole. The cadet began to sway, his mentation was slow, he was cold and clammy, and syncope appeared imminent. He was placed in bed and recovered rapidly. The cardiac rate returned to 90 per minute. One atrial premature contraction appeared, followed by atrioventricular dissociation, and the pacemaker then shifted to a secondary focus. Over the next 30 seconds of recovery, atrioventricular dissociation reappeared. The pacemaker again shifted to the secondary focus and finally returned to the primary focus in the sinoatrial node. These changes in rate and conduction appeared with the patient in bed (fig. 5).

Atropine (0.75 mg.) was administered intravenously on two occasions in an attempt to prevent the changes in conduction and rhythm associated with breath-holding. On both these occasions changes in conduction, rhythm, and syncope did not occur.

Summary and Conclusions

Although syncope may be considered lightly under many circumstances, its occurrence in industry, in an automobile, and in aviation may cause a major disaster. A better understanding of mechanisms precipitating syncopal episodes and their likelihood of recurrence can lead to prevention of accidents resulting from syncope and perhaps prevent syncopal episodes at crucial times.

This report is an analysis of syncope occurring in flying personnel. Extensive studies were done in 82 subjects to ascertain the mechanisms involved in their syncopal episodes.

It has been found convenient to consider mechanisms precipitating syncope under six general types of disorders: (1) inadequate venous return; (2) inefficient cardiac pumping action; (3) loss of arteriolar tone; (4) abnormalities in the constituents of the circulating blood (qualitative blood changes); (5) inadequate circulating blood volume (quantitative blood changes); and (6) local disorders of the central nervous system. More than one of these mechanisms may be involved in any episode of syncope.

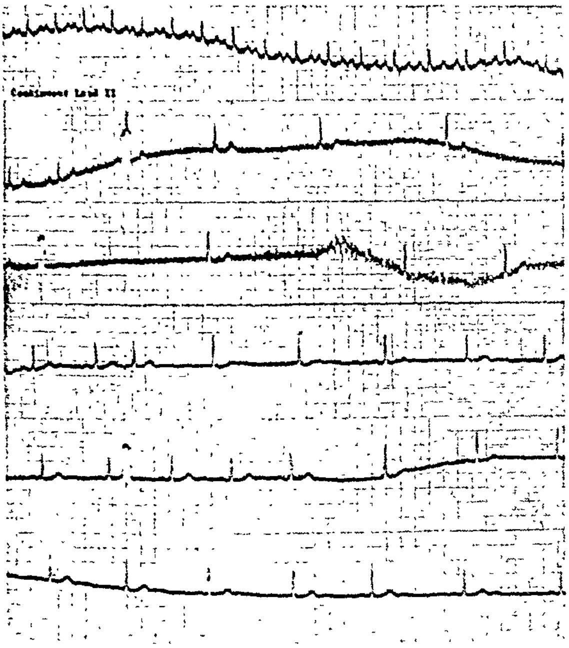

Fig. 5 (case 82).—Standard lead 2 recorded during breath-holding in standing position (first three graphs), and during recovery period (second three graphs) while patient was lying in bed. Periods of asystole were associated with near syncopal episode.

The cardiac arrhythmias are a major factor in causing inefficient pumping action of the heart. This report emphasizes the frequency of cardiac arrhythmias induced by the pulmonary stretch reflex. The stretch reflex is stimulated by common breathing maneuvers such as breath-holding and also by pressure breathing. Susceptible persons may have various cardiac arrhythmias and/or loss of peripheral arteriolar resistance with subsequent loss of consciousness. This simple chain of events may be responsible for some unexplained deaths occurring in activities involving breath-holding, e. g., underwater swimming. The stretch reflex may be stimulated after prolonged exertion. It is of particular importance in all occupations involving pressure breathing, altitude exposure, and other forms of respiratory stimulation. It is suggested that the stretch reflex may play a significant role in the operating room by producing cardiac arrhythmias and cardiac arrest during artificial respiration.

The vagal response to the stretch reflex is abolished by atropine administration. Recognition of the role of the stretch reflex in syncope and cardiac arrest, as well as a means of its prevention, has immediate application in industry and medicine.

SIDE-EFFECTS NOTED IN TREATMENT WITH METHYLPREDNISOLONE (MEDROL)

REPORT OF SEVENTY-SEVEN CONSECUTIVE CASES

F. Gilbert McMahon, M.D.
and
Edgar S. Gordon, M.D., Madison, Wis.

Sixty-seven patients and 10 healthy volunteers received treatment with methylprednisolone, with special attention to its side-effects. The largest groups of patients in the series were those with rheumatoid arthritis (18), intrinsic asthma (14), and disseminated lupus erythematosus (10). The purpose was to see whether the drug could be given in doses sufficient to exert the anti-inflammatory and other therapeutic effects of prednisone and prednisolone without widespread functional disturbances. Disturbances of body weight occurred in 40 subjects, with obesity in 14. Acne was seen in 9 and mental changes in 8; a variety of other symptoms are here tabulated. Ten cases are reported in detail, showing both the desired and the undesired effects of the drug. It promptly reduced the photophobia, lacrimation, and discomfort of the three patients with exophthalmos, but it also produced rounding of the face with other symptoms of adrenal cortical hyperfunction. Attempts to avoid these unpleasant effects by reducing the dosage led each time to the immediate return of the original symptoms. There is evidence that methylprednisolone has a stronger anti-inflammatory effect than do prednisone and prednisolone, but each patient must be evaluated carefully before it is used, and the minimal effective doses should be used for the smallest necessary time interval.

The corticosteroids are firmly established in the medical armamentarium as useful drugs in a variety of diseases. Other than as replacement therapy for adrenal insufficiency, their main application arises from their anti-inflammatory effect. Their usefulness is limited by their toxicity, and the potential hazards of steroid administration must be recognized by the physician who elects to use them. Since the introduction of cortisone in 1949 and hydrocortisone in 1951, chemical tailoring of these two molecules has been aimed in two directions: to increase the anti-inflammatory action and to decrease the side-effects (defined here as simply exaggerated manifestations of the usual physiological effects of these compounds). In the latter area, particular attention has been given to sodium retention and potassium diuresis. The synthesis in 1955 of the delta-1 steroids, prednisone and prednisolone, increased the anti-inflammatory action approximately threefold while reducing the chief undesirable side-effects. In 1957 a methyl radical was attached to the number 6 carbon atom of prednisolone to produce methylprednisolone (Medrol). Animal studies[1] showed this drug to possess from two and one-half to five times the anti-inflammatory action of prednisone. Feinberg and co-workers[2] reported that the maintenance dose of methylprednisolone in treatment of allergic diseases was about the same as or slightly lower than that of prednisone. DiRaimondo and Forsham[3] have reported this drug to have 33% greater anti-inflammatory effect than prednisolone and 60% more than prednisone.

Since there has been no previous publication devoted to the clinical side-effects of this potent new corticosteroid, we are reporting our experience in treating 77 consecutive patients with this drug. Selected case reports are also given.

Clinical Material

Sixty-seven patients at the University of Wisconsin Hospitals and Student Infirmary and 10 normal subjects, who were part of a metabolic study conducted at the Lackland Air Force Base Hospital, constitute the series reported in these observations. In the 67 patients, the conditions being treated were as follows: rheumatoid arthritis, 18; disseminated lupus erythematosus, 10; intrinsic asthma, 14; chronic ulcerative colitis, 6; hemorrhagic diseases, 3; exophthalmos, 3; chronic relapsing uveitis, 1; serum sickness, 2; sarcoid of Boeck, 1; farmer's lung, 1; malabsorption syndrome, 1; angioneurotic edema, 1; atopic eczema, 1; herpes zoster, 1; poison ivy, 4.

Dosage of methylprednisolone and duration of treatment are given in the table. All patients were on general diets unless otherwise indicated, although an attempt was made to increase calorie and protein intake in the underweight and diminish

---

calorie consumption in the obese persons. Most of the patients were initially hospitalized and subsequently followed up at regular intervals as outpatients. Others were seen at intervals of one week to one month as outpatients. A special effort was made to note the side-effects. Serum electrolyte balance and urinary glucose level were measured at least once monthly. Upper gastrointestinal x-rays with use of barium-contrast medium were not obtained unless epigastric symptoms appeared, and then stools were also examined for occult blood and red blood cell indexes obtained.

Results

All the side-effects observed are listed in the table. It is not the purpose of this paper to cite the therapeutic results obtained with methylprednisolone, but, in general, these compared favorably with those of prednisone and prednisolone. Not infrequently, however, somewhat smaller doses of the methyl derivative were successfully substituted for the delta steroids with comparable anti-inflammatory effect, indicating a higher potency of methylprednisolone. Our experience in using methylprednisolone in disseminated lupus erythematosus and rheumatoid arthritis will be the subject of another paper. Some of the important side-effects will be described here in detail.

Obesity.—Fat distribution characteristic of that seen in patients with adrenal cortical hyperfunction with Cushing's syndrome was noted in 14 patients, 4 of whom had had this finding prior to methylprednisolone administration. In two of these patients there was believed to be some diminution of the supraclavicular and cervical fat pads and moon face. Although individual variation was noted, it appeared that doses exceeding 12 mg. per day for periods of two months or longer could be expected to produce this type of obesity in most patients.

Hypertension.—Hypertension was not a significant finding in this study. Nine patients had preexisting hypertension, and no exacerbation was noted with therapy. Several patients with lupus erythematosus had progressive hypertension which was thought to be due to their underlying disease and not to the drug, since increasing the dose did not aggravate the hypertension nor did decreasing the dose diminish it. In only one patient was there a rise in blood pressure which was considered to correlate with the dose of the drug. This was in an elderly man with chronic ulcerative colitis in whom a previous labile hypertension had been noted and in whom hypertension had also followed ACTH therapy prior to the use of methylprednisolone.

Electrolyte Balance Changes.—No serum sodium or potassium level changes that could be attributed to methylprednisolone were observed. Ten young Air Force volunteers received methylprednisolone for one week as part of a more detailed metabolic study (to be reported later). Each of the patients was male, between the ages of 18 and 23 (with two exceptions, ages 39 and 41), and had normal renal, cardiovascular, hepatic, and endocrine functions. Under carefully controlled conditions, these metabolic studies during methylprednisolone administration at both 16 and 32 mg. for 24-hour levels showed that sodium clearance was slightly decreased, potassium clearance was not significantly altered, creatinine clearance was slightly increased,

Side-effects Noted from Methylprednisolone in Seventy-seven Patients

	Patients, No.	Dose, Mg./Day	Duration of Therapy, Mo.	Comment
Obesity (moon-face, fat pads)	14	12-28	3-7	Preexisted in 4 from previous steroid therapy
Hypertension	1	8	3½	Previous labile hypertension
Striae	1	24	4	
Purpura	0			
Plethora	7	12-28	2-7	
Hypertrichosis	7	6-32	2-7	
Acne	9	8-28	2-7	
Osteoporosis	0			All patients studied 1-7 mo. were ambulatory
Edema	0			
Serum electrolyte balance changes	0			
Weight gain	30			
	10	16-32	1 wk.	Normal subjects in metabolic study; av. gain, 1½ lb. (0.7 kg.)
	6	8-16	1-7	Ulcerative colitis group; av. gain, 10 lb. (4.5 kg.)
	14	4-16	1-6	Collogen disease; some on high-protein, high-calorie diet; av. gain, 5-18 lb. (2.3-8.2 kg.) without edema
Weight loss	10	4-28	1-7	6 with arthritis also on weight-reduction diets; in 2 with lupus erythematosus attributed loss to severity of underlying disease
Convulsions	2	16	4-7 days	1 also had uremia & lupus erythematosus; other was known epileptic (case 4)
Glycosuria	1	14	4	Transient, normal glucose tolerance findings
Infections	0			
Thrombophlebitis	1	16	1	51-year-old man with ulcerative colitis
Headache	0			Several with hypertension had headache, but not attributable to drug
Menstrual changes	0			
Mild GI symptoms (bloating, dyspepsia)	4	6-32	1-4	Upper GI x-rays negative; symptoms relieved with antacids
Peptic ulceration	2			
	1	16	4 days	Complicated by previous prednisone therapy associated with epigastric symptoms, by uremia, and by subsequent intravenously given hydrocortisone; autopsy diagnosis (case 3)
	1	28	4	
Chronic hypercortisonism*	1	12-28	7	Case 1
Mental changes	8			
Mild personality change	5	12-32	2-7	Euphoria, mood-swings, increased doctor-dependence
Depression, insomnia, restlessness	3	12-28	4-6	Mitigated by decreasing dose when necessary
Acute psychosis	0			

* Generalized myalgia, arthralgia, crying spells, emotional mood-swings.

and aldosterone excretion was not significantly altered. It was concluded from this study that methylprednisolone has very little effect on sodium or potassium clearance and excretion in these doses and during the brief time interval employed.

Weight Changes.—In the metabolic study with 10 normal patients, there was an average weight gain in one week of 1½ lb. (0.7 kg.). Of the 10 patients with disseminated lupus erythematosus, 7 gained weight (3 to 16 lb. [1.3 to 7.3 kg.]) and two lost weight (4 to 10 lb. [1.8 to 4.5 kg.]) during treatment. Seven patients with rheumatoid arthritis gained 5 to 18 lb. (2.3 to 8.2 kg.), without discernible edema, while on high-protein, high-calorie diets. Eight patients with this disease lost weight; six were on reduction diets, and the remaining two lost 5 and 7 lb. (2.3 and 3.2 kg.) respectively.

Glycosuria.—Only one patient developed glycosuria noted on a routine outpatient visit. A subsequent glucose tolerance test while the patient was still receiving 14 mg. per day of methylprednisolone was within the normal range.

Infection.—At least two chest x-rays were available for each patient treated for a period of longer than two months. There was neither evidence of exacerbation of latent infection nor masking of known infection.

Steroid Ulcers.—Because it was deemed desirable to note any ulcerogenic effect, no patient was given a bland diet, antacids, or anticholinergic drugs when methylprednisolone was administered. Four patients complained of bloating and dyspepsia. Results of upper gastrointestinal x-rays with barium were negative. One was receiving 32 mg. per day, another 16, and two were receiving 12 mg. per day of methylprednisolone when their symptoms appeared. When roentgenographic findings were negative, they were given antacids four times daily, with the disappearance of their symptoms, while steroid therapy was continued. One patient experienced reactivation of an old duodenal ulcer with mild hemorrhage while on therapy with 28 mg. per day of methylprednisolone (see case 3 below). Two of the Air Force subjects in the metabolic study had previously proved duodenal ulcers. Neither developed epigastric symptoms or tenderness while receiving either 16 or 32 mg. daily during the weeks of study.

Psychotic Episodes.—No episodes of acute psychosis were precipitated during this study. However, mild personality changes developed in five patients, characterized by mood swings, some euphoria, and increased doctor-dependence. Three of the patients noted insomnia. One individual who had disseminated lupus erythematosus complained bitterly of restlessness and emotional upset, with periods of weeping and depression, while at other times having a sense of euphoria. It was concluded that she was manifesting chronic hypercortisonism, and her symptoms were improved with a slow reduction of dosage (see case 1 next column).

Report of Cases

CASE 1.—A 39-year-old woman with a diagnosis of disseminated lupus erythematosus has been followed for four years. She has persistently had positive findings on L.E. cell preparations, hyperglobulinemia, polyarthritis, hypertension, maculopapular facial rash, and abnormal urinary sediment. She had also had pleural effusion, pericarditis, and congestive heart failure. She was treated satisfactorily with salicylates and/or chloroquine phosphate for the first year and one-half, but cortisone was deemed necessary in August, 1955, and since that time she has received one or another of the corticosteroids. In November, 1957, she developed symptoms that were compatible with a diagnosis of chronic hypercortisonism (myalgia, arthralgia, emotional disturbances, and a peripheral neuropathy manifested by shooting pains in the legs, hyporeflexia, hypalgesia, and hypesthesia with a stocking-like distribution). These symptoms were superimposed on previous features similar to those of patients with adrenal cortical hyperfunction with Cushing's syndrome, so that the possibility of their being caused by steroids was seriously entertained. Efforts to achieve good results with a reduction of the dose of prednisone to below 20 mg. per day failed. However, 16 mg. per day of methylprednisolone was successfully substituted. Over the next four weeks she was able to reduce this to 12 mg. per day, but no further reduction was possible. Indeed, in 10 weeks her condition again escaped control, and it was necessary to increase the dose to as high as 28 mg. per day. During the first month of receiving doses of 20 mg. per day or more, she complained of hypertrichosis, insomnia, and severe restlessness. These symptoms diminished during the subsequent two months, and she was maintained satisfactorily on therapy with 14 mg. per day. Although this patient had shown progressive hypertension during the course of her disease and required vigorous antihypertensive therapy, no change in the degree of hypertension was observed with either increase or decrease in the dose of methylprednisolone, so that the hypertension would appear to be a part of her underlying disease and not drug-induced or drug-aggravated.

CASE 2.—A 22-year-old university student had received 1,200,000 units of benzathine penicillin because of a positive finding of beta hemolytic streptococcus on throat culture. Fourteen days later he developed severe polyarthritis, generalized pruritic, morbilliform rash, generalized lymphadenopathy, and severe edema of the face, hands, and feet. This was not relieved by penicillinase injections, antihistamines, or ephedrine. He was given 4 mg. of methylprednisolone every six hours and was completely free of symptoms within 24 hours. He was maintained on decreasing doses of the steroid for two weeks until the penicillin reaction was anticipated to have cleared. His course was uneventful. No side-effects were noted.

CASE 3.—A 53-year-old woman with known severe intrinsic asthma, pulmonary emphysema, and chronic duodenal ulcer was admitted in status asthmaticus. Epinephrine, antibiotics, bronchodilators, oxygen, sedatives, and a slow intravenous drip of iodide with aminophylline were of no avail. An infusion of bovine ACTH produced sudden, severe dyspnea and cyanosis, which responded to intravenously given epinephrine. She slowly responded to large doses of orally given methylprednisolone (28 mg. per day) together with the above medicaments (except ACTH). Melena and moderate epigastric pain occurred on the fourth day of this regimen. X-ray studies revealed no ulcer crater, but chronic deformity of the duodenal bulb was identified and was assumed to be the site of her bleeding. The patient was given a strict ulcer regimen while treatment with methylprednisolone at a dose of 12 mg. per day was continued. Occult blood disappeared from the stool within four days; epigastric symptoms and tenderness were gone within one week. She has been followed up for three months with continued methylprednisolone therapy without recurrence. A modified ulcer program has been maintained.

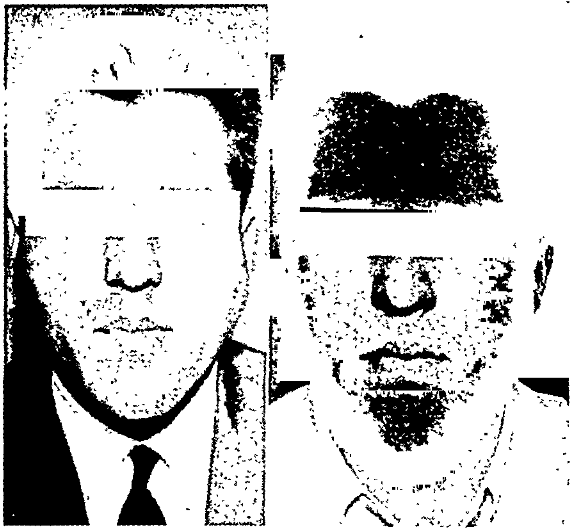
Case 4.—A 17-year-old male volunteer (as part of the metabolic study) was given 16 mg. of methylprednisolone for one week. He was known to have epilepsy, but he was otherwise in good health. He had not had a grand mal seizure in six weeks, being well-controlled with 100 mg. of sodium diphenylhydantoin given twice daily; this therapy was continued throughout the steroid study. After receiving methylprednisolone for three days, he had a grand mal seizure which lasted about four minutes, and a similar seizure occurred the next day. There were none subsequently. The possibility exists that methylprednisolone precipitated these seizures, since other corticosteroids are known occasionally to do so, as well as producing electroencephalographic changes in predisposed persons.

Case 5.—A 27-year-old man with a nine-year history of chronic ulcerative colitis was found on initial evaluation at the student infirmary to have a typical "lead-pipe" colon that was diffusely friable, bleeding and ulcerated rectosigmoidal mucosa, and pseudopolyps in the sigmoid with a 1-cm. polyp in the descending colon. He was having eight to nine loose stools daily; often these were blood-streaked. Methylprednisolone, 16 mg. per day, was given in an effort to improve his general condition and to permit him to take his doctoral examination before colectomy. Treatment was followed by prompt reduction in the number of stools to one to two a day and symptomatic improvement. After six months he had gained 18 lb. (8.2 kg.), and marked improvement of the rectosigmoid was observed proctoscopically. X-ray examination with use of a barium enema showed no change in either the colon or the polyp. He is at present scheduled for total colectomy with probable ileostomy. This patient experienced many of the typical features of adrenal cortical hyperfunction (Cushing's syndrome): moon face, supraclavicular fat pad, and mild plethora. No other side-effects have occurred.

Case 6.—A 40-year-old man with a 20-year history of chronic relapsing iridocyclitis of unknown eitology awakened one morning with marked tenderness, conjunctival injection, and total blindness in his left eye. Slit-lamp examination confirmed the exacerbation of his iridocyclitis, and he was placed on therapy with 40 mg. of methylprednisolone daily for three days, with gradual reduction in dosage over a two-week period. He noted rapid subjective improvement with prompt loss of pain and discomfort. Some improvement in vision occurred so that he could distinguish light and count near objects within three days after treatment was begun. He remarked that his response to methylprednisolone was unusual in that he did not develop the moon face or other features of adrenal cortical hyperfunction with Cushing's syndrome which he had previously experienced while on similar brief courses of therapy with cortisone or hydrocortisone. No side-effects occurred during the three weeks of therapy.

Case 7.—A 27-year-old man was seen at the student infirmary outpatient clinic complaining of swollen parotid glands of four days' duration. There were no local or systemic symptoms. Both parotid glands were firm and nontender, and the overlying skin was of normal color and temperature. No exudate was present at the duct orifices. There was no lymphadenopathy. The liver was palpable 5 cm. below the right costal margin; the spleen was not felt. A mildly pruritic maculoerythemic rash was present on the pretibial surfaces of both legs. Mumps complement-fixation titer was negative. Histoplasmin and tuberculin skin tests were negative. Chest x-ray revealed bilateral hilar adenopathy with prominent bronchovascular markings. Serum amylase, calcium, phosphorus, alkaline phosphatase, and protein levels were normal. Biopsy of the skin lesions revealed multiple groups of epithelioid cells without caseation and with a mild cellular infiltration consistent with sarcoidosis (sarcoid of Boeck). The patient was given methylprednisolone, 8 mg. four times daily, on March 11, 1958, and by March 25 no parotid swelling remained (see figure). The skin lesions had disappeared within 24 hours, and the liver was no longer palpable after the first week. A chest x-ray taken at two weeks and again in two months showed no significant changes. No side-effects occurred during the course of therapy.

Cases 8-10.—Three patients with severe "thyrotoxic" or "thyrotropic" exophthalmos were treated with methylprednisolone in doses up to 32 mg. daily. All responded favorably and promptly, with rapid reduction in photophobia, lacrimation, and the intense sense of irritation that previously had been present. Rounding of the face and an appearance strikingly similar to that of patients with adrenal cortical hyperfunction with Cushing's syndrome developed at this level of dosage in all three patients. Attempts at reduction of the dosage to avoid these unpleasant effects led each time to the immediate return of the original symptoms. All steroid therapy eventually was discarded, and it was concluded that the hazards of this form of management probably outweigh the benefits and that methylprednisolone does not possess any distinctive advantages over other steroid compounds in the treatment of this condition.



Parotid swelling in patient with sarcoid of Boeck (case 7): *left,* before treatment with methylprednisolone; *right,* two weeks after treatment.

Comment

It is not our intent to imply that corticosteroids are necessarily the treatment of choice for the diseases herein reported. Most of these patients had been on nonsteroidal or other steroidal therapy before methylprednisolone was used. It is to be emphasized that corticosteroids are seldom, if ever, curative and that their use should always be accepted as a "calculated risk." The minimal effective dose should be given over the smallest period of time needed to accomplish the desired response. It is preferable to "get in and out" of steroid therapy if possible. Whenever long-term maintenance therapy is necessary, the physician assumes the responsibility of frequently observing the patient for side-effects and constantly trying to reduce the dose so that serious side-effects are prevented.

and aldosterone excretion was not significantly altered. It was concluded from this study that methylprednisolone has very little effect on sodium or potassium clearance and excretion in these doses and during the brief time interval employed.

Weight Changes.—In the metabolic study with 10 normal patients, there was an average weight gain in one week of 1½ lb. (0.7 kg.). Of the 10 patients with disseminated lupus erythematosus, 7 gained weight (3 to 16 lb. [1.3 to 7.3 kg.]) and two lost weight (4 to 10 lb. [1.8 to 4.5 kg.]) during treatment. Seven patients with rheumatoid arthritis gained 5 to 18 lb. (2.3 to 8.2 kg.), without discernible edema, while on high-protein, high-calorie diets. Eight patients with this disease lost weight; six were on reduction diets, and the remaining two lost 5 and 7 lb. (2.3 and 3.2 kg.) respectively.

Glycosuria.—Only one patient developed glycosuria noted on a routine outpatient visit. A subsequent glucose tolerance test while the patient was still receiving 14 mg. per day of methylprednisolone was within the normal range.

Infection.—At least two chest x-rays were available for each patient treated for a period of longer than two months. There was neither evidence of exacerbation of latent infection nor masking of known infection.

Steroid Ulcers.—Because it was deemed desirable to note any ulcerogenic effect, no patient was given a bland diet, antacids, or anticholinergic drugs when methylprednisolone was administered. Four patients complained of bloating and dyspepsia. Results of upper gastrointestinal x-rays with barium were negative. One was receiving 32 mg. per day, another 16, and two were receiving 12 mg. per day of methylprednisolone when their symptoms appeared. When roentgenographic findings were negative, they were given antacids four times daily, with the disappearance of their symptoms, while steroid therapy was continued. One patient experienced reactivation of an old duodenal ulcer with mild hemorrhage while on therapy with 28 mg. per day of methylprednisolone (see case 3 below). Two of the Air Force subjects in the metabolic study had previously proved duodenal ulcers. Neither developed epigastric symptoms or tenderness while receiving either 16 or 32 mg. daily during the weeks of study.

Psychotic Episodes.—No episodes of acute psychosis were precipitated during this study. However, mild personality changes developed in five patients, characterized by mood swings, some euphoria, and increased doctor-dependence. Three of the patients noted insomnia. One individual who had disseminated lupus erythematosus complained bitterly of restlessness and emotional upset, with periods of weeping and depression, while at other times having a sense of euphoria. It was concluded that she was manifesting chronic hypercortisonism, and her symptoms were improved with a slow reduction of dosage (see case 1 next column).

Report of Cases

Case 1.—A 39-year-old woman with a diagnosis of disseminated lupus erythematosus has been followed for four years. She has persistently had positive findings on L.E. cell preparations, hyperglobulinemia, polyarthritis, hypertension, maculopapular facial rash, and abnormal urinary sediment. She had also had pleural effusion, pericarditis, and congestive heart failure. She was treated satisfactorily with salicylates and/or chloroquine phosphate for the first year and one-half, but cortisone was deemed necessary in August, 1955, and since that time she has received one or another of the corticosteroids. In November, 1957, she developed symptoms that were compatible with a diagnosis of chronic hypercortisonism (myalgia, arthralgia, emotional disturbances, and a peripheral neuropathy manifested by shooting pains in the legs, hyporeflexia, hypalgesia, and hypesthesia with a stocking-like distribution). These symptoms were superimposed on previous features similar to those of patients with adrenal cortical hyperfunction with Cushing's syndrome, so that the possibility of their being caused by steroids was seriously entertained. Efforts to achieve good results with a reduction of the dose of prednisone to below 20 mg. per day failed. However, 16 mg. per day of methylprednisolone was successfully substituted. Over the next four weeks she was able to reduce this to 12 mg. per day, but no further reduction was possible. Indeed, in 10 weeks her condition again escaped control, and it was necessary to increase the dose to as high as 28 mg. per day. During the first month of receiving doses of 20 mg. per day or more, she complained of hypertrichosis, insomnia, and severe restlessness. These symptoms diminished during the subsequent two months, and she was maintained satisfactorily on therapy with 14 mg. per day. Although this patient had shown progressive hypertension during the course of her disease and required vigorous antihypertensive therapy, no change in the degree of hypertension was observed with either increase or decrease in the dose of methylprednisolone, so that the hypertension would appear to be a part of her underlying disease and not drug-induced or drug-aggravated.

Case 2.—A 22-year-old university student had received 1,200,000 units of benzathine penicillin because of a positive finding of beta hemolytic streptococcus on throat culture. Fourteen days later he developed severe polyarthritis, generalized pruritic, morbilliform rash, generalized lymphadenopathy, and severe edema of the face, hands, and feet. This was not relieved by penicillinase injections, antihistamines, or ephedrine. He was given 4 mg. of methylprednisolone every six hours and was completely free of symptoms within 24 hours. He was maintained on decreasing doses of the steroid for two weeks until the penicillin reaction was anticipated to have cleared. His course was uneventful. No side-effects were noted.

Case 3.—A 53-year-old woman with known severe intrinsic asthma, pulmonary emphysema, and chronic duodenal ulcer was admitted in status asthmaticus. Epinephrine, antibiotics, bronchodilators, oxygen, sedatives, and a slow intravenous drip of iodide with aminophylline were of no avail. An infusion of bovine ACTH produced sudden, severe dyspnea and cyanosis, which responded to intravenously given epinephrine. She slowly responded to large doses of orally given methylprednisolone (28 mg. per day) together with the above medicaments (except ACTH). Melena and moderate epigastric pain occurred on the fourth day of this regimen. X-ray studies revealed no ulcer crater, but chronic deformity of the duodenal bulb was identified and was assumed to be the site of her bleeding. The patient was given a strict ulcer regimen while treatment with methylprednisolone at a dose of 12 mg. per day was continued. Occult blood disappeared from the stool within four days; epigastric symptoms and tenderness were gone within one week. She has been followed up for three months with continued methylprednisolone therapy without recurrence. A modified ulcer program has been maintained.

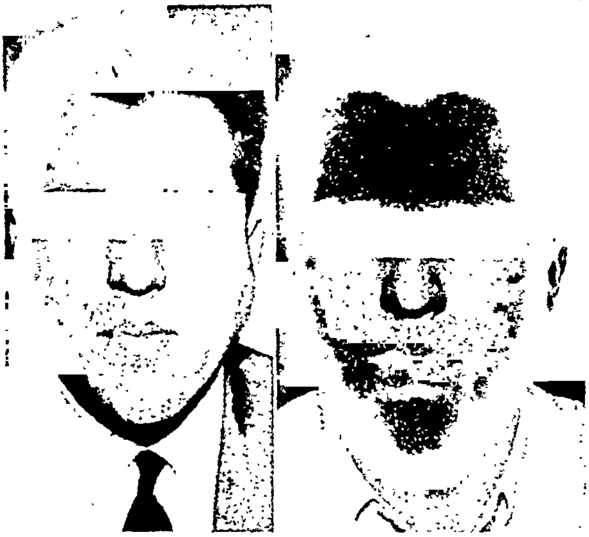
CASE 4.—A 17-year-old male volunteer (as part of the metabolic study) was given 16 mg. of methylprednisolone for one week. He was known to have epilepsy, but he was otherwise in good health. He had not had a grand mal seizure in six weeks, being well-controlled with 100 mg. of sodium diphenylhydantoin given twice daily; this therapy was continued throughout the steroid study. After receiving methylprednisolone for three days, he had a grand mal seizure which lasted about four minutes, and a similar seizure occurred the next day. There were none subsequently. The possibility exists that methylprednisolone precipitated these seizures, since other corticosteroids are known occasionally to do so, as well as producing electroencephalographic changes in predisposed persons.

CASE 5.—A 27-year-old man with a nine-year history of chronic ulcerative colitis was found on initial evaluation at the student infirmary to have a typical "lead-pipe" colon that was diffusely friable, bleeding and ulcerated rectosigmoidal mucosa, and pseudopolyps in the sigmoid with a 1-cm. polyp in the descending colon. He was having eight to nine loose stools daily; often these were blood-streaked. Methylprednisolone, 16 mg. per day, was given in an effort to improve his general condition and to permit him to take his doctoral examination before colectomy. Treatment was followed by prompt reduction in the number of stools to one to two a day and symptomatic improvement. After six months he had gained 18 lb. (8.2 kg.), and marked improvement of the rectosigmoid was observed proctoscopically. X-ray examination with use of a barium enema showed no change in either the colon or the polyp. He is at present scheduled for total colectomy with probable ileostomy. This patient experienced many of the typical features of adrenal cortical hyperfunction (Cushing's syndrome): moon face, supraclavicular fat pad, and mild plethora. No other side-effects have occurred.

CASE 6.—A 40-year-old man with a 20-year history of chronic relapsing iridocyclitis of unknown eitology awakened one morning with marked tenderness, conjunctival injection, and total blindness in his left eye. Slit-lamp examination confirmed the exacerbation of his iridocyclitis, and he was placed on therapy with 40 mg. of methylprednisolone daily for three days, with gradual reduction in dosage over a two-week period. He noted rapid subjective improvement with prompt loss of pain and discomfort. Some improvement in vision occurred so that he could distinguish light and count near objects within three days after treatment was begun. He remarked that his response to methylprednisolone was unusual in that he did not develop the moon face or other features of adrenal cortical hyperfunction with Cushing's syndrome which he had previously experienced while on similar brief courses of therapy with cortisone or hydrocortisone. No side-effects occurred during the three weeks of therapy.

CASE 7.—A 27-year-old man was seen at the student infirmary outpatient clinic complaining of swollen parotid glands of four days' duration. There were no local or systemic symptoms. Both parotid glands were firm and nontender, and the overlying skin was of normal color and temperature. No exudate was present at the duct orifices. There was no lymphadenopathy. The liver was palpable 5 cm. below the right costal margin; the spleen was not felt. A mildly pruritic maculoerythemic rash was present on the pretibial surfaces of both legs. Mumps complement-fixation titer was negative. Histoplasmin and tuberculin skin tests were negative. Chest x-ray revealed bilateral hilar adenopathy with prominent bronchovascular markings. Serum amylase, calcium, phosphorus, alkaline phosphatase, and protein levels were normal. Biopsy of the skin lesions revealed multiple groups of epithelioid cells without caseation and with a mild cellular infiltration consistent with sarcoidosis (sarcoid of Boeck). The patient was given methylprednisolone, 8 mg. four times daily, on March 11, 1958, and by March 25 no parotid swelling remained (see figure). The skin lesions had disappeared within 24 hours, and the liver was no longer palpable after the first week. A chest x-ray taken at two weeks and again in two months showed no significant changes. No side-effects occurred during the course of therapy.

CASES 8-10.—Three patients with severe "thyrotoxic" or "thyrotropic" exophthalmos were treated with methylprednisolone in doses up to 32 mg. daily. All responded favorably and promptly, with rapid reduction in photophobia, lacrimation, and the intense sense of irritation that previously had been present. Rounding of the face and an appearance strikingly similar to that of patients with adrenal cortical hyperfunction with Cushing's syndrome developed at this level of dosage in all three patients. Attempts at reduction of the dosage to avoid these unpleasant effects led each time to the immediate return of the original symptoms. All steroid therapy eventually was discarded, and it was concluded that the hazards of this form of management probably outweigh the benefits and that methylprednisolone does not possess any distinctive advantages over other steroid compounds in the treatment of this condition.



Parotid swelling in patient with sarcoid of Boeck (case 7): *left*, before treatment with methylprednisolone; *right*, two weeks after treatment.

Comment

It is not our intent to imply that corticosteroids are necessarily the treatment of choice for the diseases herein reported. Most of these patients had been on nonsteroidal or other steroidal therapy before methylprednisolone was used. It is to be emphasized that corticosteroids are seldom, if ever, curative and that their use should always be accepted as a "calculated risk." The minimal effective dose should be given over the smallest period of time needed to accomplish the desired response. It is preferable to "get in and out" of steroid therapy if possible. Whenever long-term maintenance therapy is necessary, the physician assumes the responsibility of frequently observing the patient for side-effects and constantly trying to reduce the dose so that serious side-effects are prevented.

Continued modification of the corticosteroid molecule will doubtless produce, in the future, even more potent anti-inflammatory drugs. This can be advantageous to the clinician only if the side-effects can be further minimized and if no new ones are added. It seems highly probable, however, that the major objective manifestations of adrenal cortical hyperfunction are truly the exaggerated physiological effects of the 11-oxygenated steroids of which suppression of inflammation and pituitary inhibition are inseparable parts. If this is true, then further "tailoring" of the molecule may lead to additional changes in the spectrum of biological activity, but always in the direction of a "supercortisone" which still manifests its most important and dangerous metabolic effects. Viewed in this light, there would appear to be an inescapable ceiling on the improvements that are possible in the cortisone-like steroids.

A classification of the side-effects of corticosteroids used in clinical medicine is as follows: This classification is based on the importance of the side-effect to the patient insofar as it is a statistically minor or major risk. Class 1 side-effects are virtually inevitable results of employing suppressive doses as maintenance therapy. The redistribution of fat, striae, acne, excessive hair growth, and plethora reflect an excessive amount of anti-inflammatory hormones present, but when the corticosteroids are truly needed in such doses and for such duration, the cosmetic inconvenience to a patient should not be a serious consideration. All corticosteroids available today will produce class 1 side-effects when given in sufficient doses and for sufficient time.

In class 2 are diabetes mellitus, steroid ulcers, convulsions, thrombophlebitis, hypertension, such mental changes as psychosis, electrolyte disturbances with or without edema, spread or masking of infections, and protein catabolism. These are all potentially major hazards of corticoid therapy. But their infrequency of occurrence, particularly with the newer corticoids, relegates them to a minor role when the patient is not predisposed to any of these side-effects beforehand. Each patient should be carefully evaluated before steroid administration from the point of view of development of these potentially hazardous complications. If the patient is not felt to be predisposed to any of these side-effects, then treatment may be begun, though not with immunity or without continued observations but with a statistically minor chance of producing these complications.

Class 3 side-effects do not preclude the use of corticosteroids, but the greater risk must be recognized, prophylaxis must be employed where possible, and closer observation of the patient is mandatory. With a family history of diabetes, occasional glycosuria, or borderline findings on the glucose tolerance test, the development of diabetes must be recognized as an acceptable risk of steroid therapy. When a patient has a history of peptic ulcer or, perhaps, even chronic epigastric complaints, the use of steroids must be accepted as a class 3 risk. If the benefits still outweigh the possible hazards, an ulcer regimen should be employed concurrently. In epileptic patients the use of the newer, non-edema-producing steroids will probably be attended with fewer steroid-induced seizures. Nevertheless, in treating such a person with steroids, the possibility of inducing seizures should be accepted as a major possible side-effect.

When obese or bedridden patients are treated with steroids, the possibility of thrombophlebitis should be recognized as a potential hazard. Elastic stockings or elastic bandages and ambulation, when possible, should be employed prophylactically. The production of mental changes, including an acute psychosis, during steroid therapy is not a major side-effect in most patients. But, in the emotionally labile, the borderline schizophrenic, and similar persons, steroid-precipitated psychosis must be given serious consideration. Edema formation, electrolyte balance disturbances, and hypertension do not seem to be so frequent with the newer corticosteroids. But, in a patient with preexisting labile or persistent hypertension, the administration of corticosteroids may well cause an exacerbation of hypertension, so that a potential major complication should be recognized before steroid therapy is begun.

It has been our impression that the spread of latent infection or the masking of disseminated infections in patients receiving steroid therapy is not a common occurrence unless the patient is predisposed by underlying serious disease. Special precautions should be employed to exclude latent tuberculosis, which may be reactivated by this form of treatment. In the presence of cirrhosis, carcinomatosis, lymphomatosis, and similar diseases, steroid therapy to the bedridden patient with cachexia is fraught with the hazard of dissemination of infection, and without the patient showing the usual signs or symptoms of the infection. Even prophylactic broad-spectrum antibiotics seem to be of little benefit to such patients. Protein catabolism attends the prolonged use of all currently available corticosteroids. Muscle wasting and osteoporosis is a minor hazard in nonpredisposed patients, but with bedridden and elderly patients or those with cachexia, special attempts to prevent this complication by using gonadal hormones, a high-protein diet, and ambulation should be made.

Chronic hypercortisonism has been reviewed by Slocumb and associates[4] and is produced by prolonged administration of large doses of any of the currently available steroid preparations. The symptoms are increased fatigability, emotional instability, and generalized muscular and joint aching. We have not found chronic hypercortisonism to be a necessary attendant of prolonged administration of suppressive doses of steroids in all patients. Just how some patients are predisposed to this syndrome is not clear. For the present, the possible production of chronic hypercortisonism as well as diffuse panmesenchymal reactions must be considered a major potential hazard of long-term steroid therapy in some patients. Its presence demands the tedious and slow reduction of the dosage, encouragement of the patient, extra rest, and other measures. All patients receiving significant doses of steroids for prolonged periods of time have secondary adrenal insufficiency as a result of pituitary inhibition. They depend entirely on exogenous corticoids to cope with their daily stresses. This must be recognized as a necessary hazard of steroid therapy before patients are committed to treatment. No predisposition is necessary for this side-effect. All patients receiving significant doses for maintenance therapy must be expected to have adrenal insufficiency. When such major stresses as trauma, infection, and surgery occur, an approximately threefold increase in the dosage of steroids must be employed until the stress has been removed. When steroid therapy is eventually discontinued, this should be done very gradually, and preferably by decrease of the morning doses first, since 70% of the endogenous adrenal cortical output of hydrocortisone is believed to occur between midnight and 10 a. m.[3]

In view of all these side-effects, it is imperative that each patient be evaluated carefully before steroids are employed and that the minimal effective doses be used for the smallest necessary time interval.

The side-effects of methylprednisolone noted in these 77 patients compare favorably with the generally accepted toxicity of prednisone and prednisolone for the doses and the time intervals employed. No unique side-effects were observed. Since the anti-inflammatory effect of this drug has been reported to be 33% greater than prednisolone and 60% greater than prednisone, it appears to be a valuable drug in the medical armamentarium, although continued clinical observation and experience with such a potent drug will be necessary.

Summary

Seventy-seven consecutively treated patients were observed for a period of up to seven months (mean duration of therapy, four and one-half months) while receiving methylprednisolone for various illnesses. The side-effects noted are comparable to those previously attributed to prednisone and prednisolone. No unique side-effects that could be attributed to this drug were observed.

The chief advantage of methylprednisolone seems to be in its enhanced anti-inflammatory effect, while it maintains the relatively low degree of toxicity exhibited by prednisone and prednisolone.

1300 University Ave. (6) (Dr. Gordon).

This study was supported by grants from the Wisconsin Alumni Research Foundation, the Upjohn Company, and the University of Wisconsin Medical School (Arthritis Grant).

The methylprednisolone used in this study was supplied as Medrol through Drs. Hubert C. Peltier and Harold L. Upjohn of the Upjohn Company, Kalamazoo, Mich.

PULMONARY OBSTRUCTION.—The control of the trigger factor, such as pulmonary infection precipitating cardiac failure, is of paramount importance. Digitalization, oxygen administration, and other supportive measures should be administered. We should like to warn against the use of opiates and intensive antimony treatment, the latter being toxic to the myocardium. These patients may remain asymptomatic for an indefinite period of time. Increasing knowledge of this condition and the opportunity to diagnose it clinically will enable us to better evaluate the treatment and prognosis of these patients. At present the prognosis is apparently poor once cardiac decompensation supervenes. The governing factor in the short longevity of these patients is the mechanical impairment caused by the irreversible pulmonary arterial and arteriolar obstruction. We agree with other reports that patients with a pronounced increase in pulmonary artery pressure are in a continual danger of death and hence are poor surgical risks.—J. Marchand, M.D., R. A. EMERGENCY COMMISSUROTOMY IN INTRACTABLE PULMONARY EDEMA

REPORT OF TWO CASES

Hans U. Wessel, M.D.
and
James R. Webster Jr., M.D., Chicago

Acute, intractable pulmonary edema appeared in a patient who was being prepared for mitral commissurotomy. The operation was postponed, and the patient died. There was reason to believe that immediate performance of the operation would have given the patient a chance to survive. Accordingly, in two other patients, with mitral stenosis, who developed pulmonary edema refractory to medical treatment, the operation was done at once. The improvement was immediate, and both patients survived. Since pulmonary edema may set in suddenly during diagnostic procedures or during preparations for surgery, the possible need for emergency commissurotomy must be kept in mind, but it is better to follow the patient closely and to advise surgery before intractable pulmonary edema becomes an imminent threat.

Mitral commissurotomy is usually done as an elective procedure. The patient is operated on after an optimal state of cardiac compensation has been achieved. We first became personally acquainted with the problem of mitral stenosis in which mitral commissurotomy was performed as an emergency procedure because of intractable pulmonary edema in 1955 when a 22-year-old woman was admitted to Chicago Wesley Memorial Hospital for mitral commissurotomy. She gave no history of rheumatic fever. Two years prior to admission she began to have progressive exertional dyspnea, palpitation, and precordial pain with radiation to the left arm and shoulder.

Physical examination, x-ray studies, and the electrocardiogram (ECG) were diagnostic of rheumatic heart disease and mitral stenosis. Right heart catheterization confirmed the clinical impression, showing marked elevation of the right ventricular, pulmonary artery, and pulmonary venous capillary pressures. The cardiac output was diminished and the mitral valve area was estimated to be about 0.5 sq. cm.

The patient was digitalized on admission and taken to surgery three days later. She was given morphine sulfate, atropine, and scopolamine on the morning of surgery. After she had received about 50 mg. of thiopental (Pentothal) intravenously, she suddenly developed acute pulmonary edema. There was marked cough productive of a bloody, frothy sputum, hyperventilation, and wet rales throughout both lungs. The pulse rate increased to 150-200 per minute. A portable x-ray confirmed the diagnosis of severe, acute pulmonary edema. The patient was taken back to her room. Treatment with morphine sulfate, oxygen by mask, and intermittent positive-pressure breathing and antibiotics was of no avail. The temperature rose to 104 F (40 C) rectally. After an initial slight improvement the patient's condition deteriorated rapidly and she died the following day.

Autopsy revealed mitral stenosis with evidence of active rheumatic myocarditis. There was hypertrophy and dilatation of the heart, particularly the right side. Chronic, passive hyperemia was present in the lungs, kidneys, spleen, and liver. The lungs weighed 2,000 Gm. and were quite firm in consistency. Microscopic sections revealed pulmonary edema, bronchopneumonia, and diffuse interstitial fibrosis. Death in this patient was attributed to pulmonary edema and bronchopneumonia. In retrospect it was thought that this patient should have undergone mitral commissurotomy in spite of her precarious condition and that opening of the mitral valve with relief of the obstruction offered the only chance for survival.

During the next two years, we observed two additional patients with mitral stenosis who suddenly developed severe, intractable pulmonary edema. In the first patient this was precipitated by right heart catheterization; in the other by an acute upper respiratory infection. Both patients were operated on during the state of pulmonary edema which medical management had failed to improve. Both patients survived and, in both, relief of obstruction at the mitral valve was almost immediately followed by clinical improvement of the pulmonary edema.

Report of Cases

Case 1.—A 29-year-old woman was admitted to Chicago Wesley Memorial Hospital for cardiac catheterization. She gave no history of rheumatic fever. Seven years before, during labor, she was first seen by a heart specialist and told that she had heart disease. She remained asymptomatic until one and a half years prior to admission. At this time progressive exertional dyspnea, palpitation, and cough began. There were several episodes of hemoptysis. Ankle edema had appeared three months before admission and the patient had been digitalized.

On physical examination she was well developed and nourished. Inspiratory wheezes were heard throughout the lungs. There was no venous distention or abnormal arterial pulsations. The cardiac rhythm was regular at a rate of 90 per min-

---

ute; blood pressure was 120/80 mm. Hg. The left heart border could be percussed 14 cm. to the left of the midsternal line in the fifth intercostal space. A right ventricular parasternal thrust was felt and a diastolic apical thrill was palpable. There was an apical, middiastolic, low-pitched rumble ending in a presystolic crescendo. The murmur was transmitted to the left axilla and toward the back. The pulmonic second sound was louder than the aortic second sound, and the first sound was loud and snapping over the mitral area. The liver was palpated one finger breadth below the right costal margin. There was no peripheral edema. X-ray showed moderate left atrial and right ventricular enlargement. There was dynamic distention of the main-stem pulmonary artery and minor engorgement of the pulmonary vasculature. The ECG showed right ventricular hypertrophy and strain and sinus tachycardia. Rare fusion beats were observed.

During right heart catheterization the patient developed acute pulmonary edema. The pulse rate increased to 150 per minute and she became cyanotic and extremely restless. Treatment with morphine sulfate, aminophylline, lanatoside Cedilanid C, rotating tourniquets, and oxygen breathing with intermittent positive pressure afforded no improvement. The patient showed only minimal response to subsequent intubation, oxygen breathing, and defoaming with ethyl alcohol mist and venesection. Immediate mitral commissurotomy appeared to offer the patient her only chance of survival.

At surgery, the lungs were of liver-like consistency and showed very little evidence of aeration. The left atrium was entered through the left atrial appendage. No thrombi were found. The mitral valve was so stenotic that no orifice could be felt with the examining finger. A pea-sized mass of calcium was attached to the lateral leaflet near the orifice on a flexible pedicle which hopped up into the atrium during systole and fell into the mitral orifice during diastole. After considerable manipulation, it was possible to finger fracture the match-sized orifice and to dilate it to finger size. This opened the anterior commissure for a distance of 1 to 1.5 cm. During the manipulation, the calcium piece disappeared into the circulation. The carotid arteries were compressed during each manipulation of the valve.

During one of the manipulations the heart went into ventricular fibrillation. Cardiac massage was begun and electrical defibrillation carried out. This threw the heart into asystole. With subsequent massage and injection of calcium chloride into the right ventricle, a normal rate and sinus rhythm was restored after two to three minutes. The patient was given 400 mg. of procainamide intravenously.

The anterior commissure was finally opened for about 2 to 2.5 cm. The posterior commissure could not be opened because of marked shortening and matting of the papillary muscles and chordae tendineae and their fusion with the valve leaflets. At the termination of the procedure the lungs, previously of liver-like consistency, were partially aerated and pink in color. The peripheral portions were soft and pliable and well aerated.

A tracheotomy was performed and the patient's respiration assisted with a Bennett respirator during the day after surgery. The cyanosis cleared within three days and within five days there was no radiographic evidence of pulmonary edema. Nine days after surgery the tracheotomy tube was removed. During the entire postoperative course, the blood pressure remained stable at normotensive levels and the urinary output was adequate. The temperature remained elevated for 10 days. A respiratory alkalosis with hyperpotassemia corrected itself after discontinuation of the respirator. The patient was discharged on the 23rd postoperative day. Maintenance digitalization has been continued. There has been no arrhythmia or decompensation currently (28 months after surgery). She is in functional class 2 according to the American Heart Association classification.

Case 2.—This 49-year-old man was admitted to Chicago Wesley Memorial Hospital on the evening of Feb. 13, 1958, in acute pulmonary edema. He was known to have rheumatic heart disease with mitral stenosis and atrial fibrillation. Two weeks before admission he contracted an upper respiratory infection. He remained at home for five days and received penicillin and symptomatic treatment. On the day of admission, he experienced a return of the chills, fever, generalized malaise, and cough. He left work and went home, at which time he became quite dyspneic. He was brought to the hospital for examination. He had noted no chest pain, ankle edema, palpitation, or sudden gain in weight. On admission, he appeared to be acutely ill and was extremely dyspneic and cyanotic. Blood pressure was 165/115 mm. Hg, pulse 140 and irregular, temperature 101 F (38 C) rectally. His lungs were filled with wet, noisy rales and no heart tones could be heard because of this interference. There was no hepatosplenomegaly and no peripheral edema.

Treatment consisted of oxygen, aminophylline intravenously, rotating tourniquets, venesection, and penicillin. There was immediate improvement, and two hours after admission the chest was clear except for some rales at the right base. With the patient in the left lateral decubitus position, a middiastolic apical murmur could be heard. That evening the leukocyte count was 57,000 per cubic millimeter, with 96% segmented neutrophils, 2% lymphocytes, and 2% monocytes. Nonprotein nitrogen level was 31.5 mg.%; fasting blood sugar level was 107 mg.%, and sedimentation rate (Wintrobe) was 35 mm. in the first hour, with urine normal. An ECG showed atrial flutter with a variable block and an atrial rate of 450. There was also evidence of right ventricular hypertrophy and digitalis effect. A chest x-ray revealed engorgement of the pulmonary vessels with an increased density of the lungs indicative of pulmonary edema. The heart was moderately enlarged with a markedly enlarged left atrium.

He did well for 18 hours after admission. Chloramphenicol was added to therapy because a sputum smear showed a large number of staphylococci. Sputum culture later showed only staphylococci and vancomycin was also given. His color and breathing were good and he rested comfortably during the day. On the next evening the patient once more experienced an episode of pulmonary edema which was again relieved by morphine, aminophylline, oxygen, and rotation tourniquet. However, this second attack lasted considerably longer and was more difficult to control. His temperature rose to 104.6 F (40 C). Even after the acute pulmonary edema had cleared, he continued to have rales and slight dulness at the right base.

On Feb. 15, he once again went into pulmonary edema. This time he was quite refractory to all therapeutic measures previously employed. Meperidine (Demerol) given intravenously and aminophylline temporarily improved his condition. However, he remained in subacute pulmonary edema. Immediate relief of the mitral stenosis appeared to offer the only chance for survival. On opening the chest, it was noted that the lungs had the consistency of liver and appeared to be poorly aerated. Little expansion of the lung could be seen, even with intermittent positive-pressure breathing. The left atrium was entered through the left atrial appendage which contained several thrombi. The mitral valve orifice was located in the posterior third of the valve and was too small to admit a fingertip. Satisfactory opening of the valve was achieved by a commissurotomy knife. By the time the pericardium was closed, the liver-like consistency of the lung had disappeared and the lung appeared soft and well aerated and of a bright pink color. This dramatic change occurred within a few minutes after the valve had been opened. However, blood pressure dropped precipitously and respiration became irregular. Intermittent positive-pressure breathing through the endotracheal tube resulted in improvement and stabilization of blood pressure.

He was returned to his room much improved over his preoperative status. The lungs were appreciably clearer with only a few rales present at the right base. The temperature was 105 F (40.56 C) rectally. During the next few days the temperature gradually decreased, as did the leukocyte count, and the lungs became almost completely clear. The day after surgery the nonprotein nitrogen level was 95%; the creatinine 3.6 mg.% and the carbon dioxide 18 mEq. This azotemia responded to conservative management. He was discharged one month after admission and 27 days after surgery. At this time the nonprotein nitrogen level was 30 mg.%, the chest x-ray showed no infiltrates, and an ECG showed a coarse fibrillation with a ventricular rate of 80.

Comment

Pulmonary edema in mitral stenosis cannot be explained on the basis of left heart failure. The basic physiological derangement is impedance to blood flow from the lungs due to obstruction at the mitral valve. With a given area, the pressure gradient across the mitral valve is directly proportional to the square of the flow across the orifice.[1] Thus any rise in cardiac output must be accompanied by a rise in left atrial pressure which is transmitted backward into the pulmonary venous, capillary, and arterial system. Theoretically pulmonary edema should occur if the pulmonary capillary pressure exceeds the osmotic pressure of the plasma and the lymphatics are unable to drain the excessive filtrate.

Common precipitating factors are sympathetic stimulation caused by excitement, exertion, exposure to cold, fright, and anger leading to tachycardia and vasoconstriction. Tachycardia results in a shorter diastole with further impairment of left atrial emptying. Vasoconstriction produces redistribution of the blood with its accumulation in the lungs.[2] Robin and Thomas [3] in a study of patients in whom a postmortem diagnosis of pneumonia and pulmonary edema had been made at the Peter Bent Brigham Hospital reported a close interrelationship between these two entities and stated that they frequently coexist and that the occurrence of one predisposes to the development of the other.

Pregnancy in patients with mitral stenosis commonly predisposes to pulmonary edema. Lawler and Gallagher,[4] in a study of mitral stenosis and commissurotomy during pregnancy, reported a rise of cardiac output and blood volume early in pregnancy leading to a 32 to 60% increase above nonpregnant levels by the 28th and 32nd week. This was followed by a moderate decrease until delivery, postpartum rise, and ultimate return to previous levels. Baker and co-workers in 1952 [5] recommended commissurotomy for the treatment of relapsing pulmonary edema, and presented nine patients on whom emergency mitral commissurotomy was performed, with one death. Bailey [6] reported that his patients who had previously suffered from pulmonary edema did well during surgery and had good results. It was his opinion that "history of acute paroxysmal pulmonary edema . . . would seem to urge prompt intervention lest a subsequent attack prove fatal." Bramwell,[7] in a review of the hazards of pregnancy in women with heart disease, spoke in the same tenor when he stated "pulmonary edema is in fact one of the most urgent indications for mitral valvotomy." The same view was expressed by Mulcahy [8] in 1957. He advised emergency valvotomy if pulmonary edema persisted in spite of medical treatment. He reported on 132 cases of heart disease seen during pregnancy within a five-year interval. Of these patients 71 had pure mitral stenosis, 15 mitral stenosis and insufficiency, 15 combined mitral and aortic disease, 9 pure mitral insufficiency, 9 had aortic stenosis or incompetence, and 6 had congenital heart lesions. Seven of these patients underwent mitral commissurotomy because of progressive deterioration. O'Connell and Mulcahy [9] reported an emergency mitral commissurotomy performed because of intractable edema. The patient survived. Another case of emergency mitral commissurotomy during pulmonary edema with survival was reported in 1957 by Dellepiane.[10] The case reported by Krauss and co-workers [11] was a quasi emergency mitral commissurotomy in a woman whose cardiac status had deteriorated rapidly since the fourth month of gestation and she went into pulmonary edema during cardiac catheterization. This patient also survived and had a good result. In contrast, Bramwell [7] saw 11 deaths due to heart failure in pregnancy. In this group were 7 of 16 patients with mitral stenosis who developed pulmonary edema. None of these underwent surgery.

The results of mitral commissurotomy in cases such as ours and those cited above should, as a rule, be good. Good results can be anticipated in patients whose pulmonary hypertension is primarily due to obstruction at the mitral valve, and who are not "protected" against pulmonary edema by secondary precapillary pulmonary arteriolar stenosis and/or chronic right heart failure. Hence, the occurrence of pulmonary edema may mean that a good result will be obtained from surgery, since it requires reasonably good cardiac function for it to develop. However, even though emergency mitral commissurotomy during a state of intractable pulmonary edema affords a fair chance of survival with a good result, it is obvious that operation is preferable before such an emergency situation occurs. Our foremost obligation to our patients with mitral stenosis is to study and follow each one carefully and to advise surgery before pulmonary dynamics make intractable pulmonary edema likely.

1137 Maple Ave., Evanston, Ill. (Dr. Wessel).

This study was supported in part by the Schermerhorn Memorial Fund.

Cardiac catheterizations were performed by Dr. Paul Kezdi. Operations were performed by Dr. Edward E. Avery.

THERAPEUTIC CONTRIBUTIONS OF THE DOCTOR OF PHYSICAL MEDICINE

APPLICATION IN THE CLINICAL PRACTICE OF MEDICINE

Leslie Blau, M.D., Binghamton, N. Y.

The functions of a physiatrist include administration, diagnosis, therapy, and research. For successful therapy it is necessary that he choose modalities, specify times and intensities, make sure of the proper psychiatric approach to the patient on the part of all who administer treatment, and adjust the treatment in general to the needs and responses of the patient. Two case histories illustrate how lesser physical ailments can lead through circumstances to prolonged disability and how physical therapy based on correct diagnosis can relieve the physical condition and rehabilitate the patient. If valuable methods of treatment are not to be misused and neglected, physicians must prepare themselves to use the modern clinical approach offered by physical medicine and to avail themselves of the necessary ancillary services.

In a previous paper the functions of a physiatrist were described.[1] They are administration, diagnosis, therapy, and research. In addition, frequently he has coordinative functions designed to integrate the ancillary services into a central team for successful psychosocioeconomic adjustment of the patient. The role of the specialist of physical medicine as a diagnostician has been elaborated on in detail and supported with a variety of clinical material which clearly illustrated that treating patients with haphazard or tentative diagnoses may lead to poor results or even to untoward consequences to the patient.

A great many factors other than diagnosis deserve serious consideration if we are effectively to attain the desired therapeutic goal. Some of these are the choice of modality, the mode of administration of treatment, dosage, the *proper psychiatric approach* of those who treat the patient, the patient's inner conflicts, his reaction to the disease, undue prolongation or abrupt interruption of treatments, secondary gains, and, sometimes, even malingering. The purpose of this paper is to explain the reasons why the awareness of these factors is important in the attainment of therapeutic goals and why the clinical acumen of the physiatrist who is usually in charge of therapies is vital and why his services should be available at all times.

Proper Modality

In selecting the proper modality for the treatment of a patient there are a number of considerations. Some of these stem from the effect of the agent and some from the reaction of the patient.

The effect of a physical agent, just like the effect of a drug, can, as a rule, be anticipated. For example, we know that diathermy, infrared lamps, and ultrasonics are heat modalities. Thus, we use them to improve local circulation either by direct heating or by reflex vasodilatation to hasten removal of inflammatory waste products, to allay pain, and to reduce muscle spasm. It should be kept in mind, however, that the random selection of such heat modalities for therapy will result in a great many disappointments not only by poor results but sometimes by deleterious effects to the patient. The reason is that these three modalities develop heat as their principal effect; nevertheless, their mechanism of production, side-effects, and physical characteristics are widely different, creating specific

---

Medical Director, Rehabilitation Services, Inc.

indications and contraindications that the clinician must keep in mind in selecting them. It may be all right to prescribe infrared heat for many conditions, such as malignancy, osteomyelitis, or postfracture with metallic implants, but diathermy is contraindicated because it may hasten metastasis by its deep penetration, it may have decalcifying effect on the bone, and it will overheat metallic implants.[2] Ultrasonic energy may be a fine modality for many nonparalytic neuropathies, but for others it may be harmful, since it may aggravate weakness as has been shown on animal experiments with electromyography.[3] This discussion could go on not only in regard to these modalities that have been selected to illustrate the point but in regard to all other physical agents, even those as divergent as massage, electrical stimulation, or the many forms of therapeutic exercises.

The other major consideration in the selection of a modality is the reaction of the patient. Here we must think of such factors as general physical condition, age, sex, and individual reactivity. The general physical condition of patients must be considered in prescribing physical treatments; for example, one does not expose a debilitated restless individual to ultraviolet rays because chances are that he may become more restless and irritable. Age is another factor to be considered; hot foot soaks are dangerous in an older person who may have arterial insufficiency in the limbs. Sex also has discriminating limitations; for instance, ultrasonic energy over the lower abdomen of a female patient is not recommended because of the selective sensitivity of the ovaries to this form of physical agent.[3] Individual reactivity cannot be predicted in advance unless the patient's history furnishes such information. An unsuspected individual susceptibility may create uncomfortable situations or even a dire emergency. I remember such a case rather vividly. I prescribed for the patient histamine ion transfer for wry neck. He was in the hospital for a chronic neurological condition, but one morning he woke up with painful, tender muscles in spasm in the posterior aspect of his neck. It is known that histamine as a counterirritant may be helpful, in addition to massage and mobilization exercises, in such a case. He gave no history of asthma, hay fever, or other allergic manifestations. Nevertheless he had individual intolerance to this agent, inasmuch as in 30 to 60 seconds after initiation of this treatment he developed a severe reaction, consisting of generalized urticaria, headache, and feeling of tightness in his chest. It necessitated prompt discontinuation of treatment. He needed epinephrine for relief to prevent a full-blown asthmatic attack. Individual sensitivity is not at all an oddity. A patient, not long ago, had pain in the lower part of her back. As I was taking her history, she found that diathermy was contemplated for her. She immediately stated, "Oh, no! I get a severe headache whenever they give that to me." Peculiarly enough, the attending physician referred her to us with the specific recommendation of diathermy, without knowing the patient's intolerance to it.

Mode of Administration

In the great majority of patients referred for physical medicine and rehabilitation, patients feel the first time that actually something is done for them. Therefore, the environment must be pleasant, safe, and congenial. If, by necessity, unpleasant experiences cannot be avoided, they should be well explained to the patient. This statement is being made with reference to stretching and mobilization exercises. Many patients are referred to physical medicine who suffer from conditions in which pain is the predominant symptom, and the immediate danger is functional loss by keeping the joint in a favorable position. To illustrate my point, I am going to discuss those patients who suffer from rotator cuff syndrome of the shoulder, first described by Codman [4] and more recently by Moseley.[5] These are the patients whose condition had been labeled supraspinatus tendinitis, subdeltoid bursitis, capsulitis, and periarthritis. Years of latent, slowly burning inflammation may be lighted up with an acutely tender, excruciatingly painful shoulder.[6] The patient will be reluctant to move such a joint, which will inevitably result in secondary fixation. The foremost obligation to these patients is to maintain function. A variety of treatments have been advocated for the painful shoulder. Recommendations range from such extremes as to do nothing else but allow the patient simple rest, giving him sedation for pain,[7] to the excision of the acromion for supraspinatus syndrome.[8] In my experience, the best way of treating such patients is to relieve them from pain at any cost to ready them for range-of-motion exercise. During the acute phase, which usually lasts three to seven days, the patient should receive personal attention by the physician. Exercise must be strongly assisted or administered with the patient passively relaxed—never against force. It could be administered as a form of examination or recheck. Preferably, it should be done after the patient has received the most suitable pain-relieving measure, be that local injection of hydrocortisone with procaine, ultrasonic or infrared heat therapy, or short wave diathermy. I feel that x-ray and such toxic drugs as phenylbutazone should be reserved for very stubborn occasional cases, only as the last resort. If motion against gravity is not possible, Codman's test [9] will always succeed to attain 90 degrees or more abduction of the shoulder. A doctor should be available who has the time and clinical competence to spend with such patients, if frozen shoulders are to be prevented.

Dosage

To many people, professional or otherwise, dosage and prescription have no practical connotation in regard to the therapeutic application of physical agents. There is nothing farther from the truth then the idea that physical agents are always innocuous. It is especially true at this day and age because we use such energies as ultrasonics and microwave diathermy that give relatively little subjective feeling of heat yet heat deep tissues to a considerable degree with a potential danger of damage. The importance of dosage is relevant in regard to other energies used in physical medicine. We exercise a great many patients who are crippled from cardiovascular or respiratory disease and who would suffer from exercise and activity therapies if they were not given dosage according to cardiovascular tolerance and physical fitness.

Psychiatric Approach

The psychiatric aspect of treatment management is that all important, frequently intangible, often ill-understood, and neglected factor of everyday therapeutics which can help or defeat in the attainment of goals. From the first to the last meeting with the patient, the physician must be aware of his *de facto* relationship with him. He must know whether the patient has confidence in him, trusting his professional skill and sincerity. Is the therapist only tolerated by him? The patient's inner conflicts, motives, secondary gains, family relationship, and genuine reaction to his disability must be learned and kept in mind. Since the overwhelming majority of patients have chronic ailments, therapists must have a clear understanding of their goals. Neither undertreatment nor overtreatment can be done. This can be accomplished by precise timing and correlation of results with the attainment of a psychological peak and subjective gratification of the patient. When such a culmination of results is not appreciated, usually an anticlimax follows with precipitation of symptoms, grossly exaggerated by functional overlay. The following cases will illustrate some of these points.

Report of Cases

Case 1.—A 43-year-old woman was referred to me in January, 1957, for opinion and indicated treatment. Her complaint was pain in the lower part of her back since March, 1950, when the following incident took place. She worked as a chambermaid for a hotel; she was moving luggage from one place to another, and, allegedly, she developed such severe pain in her back that she fell on the floor. After about one-half hour, she felt better and cleaned up more rooms. She had to carry luggage again, and she lost consciousness. She was hospitalized for two weeks of rest and heat therapy. Allegedly, x-ray findings were negative. Subsequently, this patient received diathermy to her back three times a week for six years (until October, 1956). She had a thyroidectomy in September, 1951, one and one-half years after the alleged back strain, claiming that she began to be shaky and nervous after the accident.

Examination revealed a paucity of positive findings. She gave a long history while sitting in a chair without showing discomfort. She undressed, favoring her back as she did so. She alleged severe tenderness over the suboccipital, the posterior cervical, and lumbar regions. She moaned and groaned in anticipation of pressure. When she was asked to bend forward, she did so reaching only 20 in. from the floor with her knees extended, saying continuously, "I can't." Results of Faber, Ober, Eli, and straight leg raising were negative, but each maneuver caused her "terrific" pain accompanied by tearless cries. Neurological examination was negative. After the examination she asked her husband to fix her garter and to hand her her clothes, completely favoring her back.

My conclusion was that patient had conversion hysteria. She was a dependent individual, and more physical therapy would have further fixed her disability. Several days later, after consultation with the referring physician, I told her of this opinion. She reluctantly admitted that she had been seen by a psychiatrist, who offered her therapy, but she refused it. At this time she promised to follow through.

Comment.—This case indicates unjustified overtreatment, consisting of six years of diathermy, three times weekly. It helped her to become more dependent, fix her disability, and become virtually a useless cripple. This was a basically unstable individual, who, I believe, with competent guidance consisting of reassurance, motivation, and 6 to 10 physical treatments, could have been channeled back into useful existence.

Case 2.—A 36-year-old woman was referred to me with the diagnosis of torticollis on April 29, 1957, for opinion and indicated treatments. She complained of pain and stiffness in the posterior aspect of her neck, with radiation to her shoulders, of 12 days' duration. She related, also, that the referring physician treated her with oral medication and infiltrated her neck once, seven days prior to her referral. She had not worked since the onset of her pain.

The patient walked into the office holding her head rigidly tilted to the right and flexed; she had round shoulders, and she stooped. She appeared frightened and completely overwhelmed by her disability and also by her husband and mother, who insisted on accompanying her into the examining room. Examination revealed no tenderness. She had normal strength of the sternocleidomastoid muscles. She moved the cervical spine in all directions to almost full range; however, she required a great deal of encouragement to do so. Reflexes in the upper extremities were normal, and there was no sensory change to pin prick. Shoulder and upper extremities were also found normal as to strength and range.

My impression was that the patient had a dependency reaction, being overprotected by her mother and husband. She was without indicated medical guidance, and from a trivial wry neck she developed a conversion reaction. On the basis of this conclusion, I reassured her and gave her, immediately, Sayre sling cervical traction against 2.5 lb. of weight resistance. This was the least amount that gave her the feeling of tension to enable her to relax, permitting cervical rotation movements. This was accomplished without obvious discomfort, and the procedure was followed by ultrasonic, infrared, and massage therapy to relieve her from symptoms of disuse. She left the office as a changed person, cheerfully stating, "I feel much better." Subsequently, she received a total of five treatments under my direct personal supervision. After the third treatment she returned to her job as a cosmetic saleslady.

Comment.—By demonstration of personal interest in this patient, use of kind firmness accompanied by reassurance, indicating that there was nothing seriously wrong with her yet acknowledging that her symptoms were bad enough to cause her discomfort, and use of a few physical treatments, it was possible to prevent the development of conversion hysteria.

Summary and Conclusions

There are many factors that interplay in the attainment of therapeutic goals. Physical energies are often ill applied, and therapeutic results are unsatisfactory. As a result, wrong conclusions are drawn, and a valuable method of treatment is misused or wrongfully condemned. The physician is no longer able to fulfill all therapeutic needs of the patient. Nobody in clinical medicine can escape the need of ancillary services, and none of us can afford to sacrifice the modern clinical approach offered by physical medicine.

SCRAP IRON INTOXICATION

Richard H. Gadsden, Ph.D., R. Ramsey Mellette, M.D.
and
William C. Miller Jr., M.D., Charleston, S. C.

"Scrap iron", an inexpensive alcoholic beverage, is so named because of its peculiar metallic taste. The chief ingredients are isopropyl alcohol and naphthalene. Fifty patients with scrap iron intoxication have been arbitrarily divided into five groups according to their predominant clinical picture. The largest group consisted of patients with acute brain syndrome as manifested by motor restlessness, hallucinations, illusions, extreme apprehension, tremor, and general disorientation. These symptoms, which are identical to those exhibited by a patient experiencing delirium tremens from ethyl alcohol, are usually reversible on abstinence from alcohol. There is a subsidence of most of the symptoms in the patients with toxic psychoses within several days, simply with supportive therapy consisting of use of fluids, vitamins, and sedation or tranquilizers.

From time immemorial man has used alcoholic beverages to deaden psychic and physical pain, to celebrate victories, and to escape from reality. When it has been impossible for men to secure the better alcoholic beverages, they seek, and find, substitutes. With the present price of legally obtainable alcoholic beverages at an all-time high, there is naturally a large market for cheap alcohol and substitutes.

The use of "scrap iron," or "scrap," as some of the users refer to it, was brought to our attention by a marked increase in the number of persons with toxic psychoses who were admitted to psychiatric hospitals. Bizarre physical and laboratory findings were obtained in the study of some of these confirmed scrap iron indulgers; this led to further studies of the patients who used scrap iron and to the toxic effects produced by this concoction.

Investigation into the production or source of scrap iron was not as rewarding as had been hoped. Isopropyl alcohol and naphthalene were identified in the blood specimen obtained from our first patient. Subsequent analysis of his half-full bottle of scrap iron showed isopropyl alcohol and naphthalene in strong concentration. We were greatly interested in determining the reason behind the addition of the naphthalene. The only scientific reason elicited for this addition was the statement of those patients consciously aware that its addition added some "kick to the drink." Obviously, this is a drink of "voltage rather than vintage." It was stated by some of the informants that this alcohol preparation was made in 50-gal. galvanized drums. The base materials are yeast, cracked corn or corn meal, and sugar. Quite often Clorox (a commercial

---

Assistant Professor of Chemistry (Dr. Gadsden) and assistant psychiatric residents (Drs. Mellette and Miller), Medical College of South Carolina.

preparation used for cleaning purposes) was used as a catalyst in the fermentation. The addition of the isopropyl alcohol (in the form of rubbing alcohol) is made after 48 hours have been allowed for the fermenting of the mash in the drum, at which time moth balls are also added to the mixture. The galvanized drums apparently give the preparation a metallic taste; hence, the origin of the term scrap iron.

Chemical Analysis

Qualitative Analysis.—The qualitative detection of isopropyl alcohol, naphthalene, and beta-naphthol in the urines of patients thought to be consumers of scrap iron was carried out in the chemistry department of the Medical College of South Carolina. The following methods were used.

Ten cubic centimeters of urine was distilled through a water-cooled condenser; the first 5 cc. of distillate was collected. A standard containing small amounts of isopropyl alcohol, naphthalene, and beta-naphthol was treated in the same manner as the sample. The isopropyl alcohol was detected by the method of Brown,[1] the vanillin-sulfuric acid reagent being prepared fresh before each testing period. The presence of naphthalene was detected by the method of Koelsch,[2] with the slight modification of substituting a dilute solution of bromine water for the chlorinated lime solution. This manipulation resulted in no false-negative reactions with the standard solutions and apparently stabilized the color development.

Confirmatory tests for the presence of naphthalene were carried out by the method of Penzoldt.[3] This depends on the formation of a characteristic green color when the naphthalene solution is underlayed with concentrated sulfuric acid. On all urine specimens showing positive reactions for naphthalene, the method of Pellerin[4] was used to demonstrate the presence of beta-naphthol. No quantitative analyses for naphthalene were attempted since detection of beta-naphthol in the urine would indicate ingestion, absorption, and metabolism of naphthalene.

In addition to detecting toxic products in the urine of the patients, we were able to analyze several dozen bottles of bootleg whiskey which had been confiscated by the police department during the several months during which we were carrying out our investigation. Eighty per cent of these bottles revealed the presence of isopropyl alcohol in large amounts, and 60% showed the presence of naphthalene in significant amounts.

Quantitative Analysis.—The chemical methods available to date do not permit the quantitation of a single alcohol in a mixture containing another alcohol or alcohols. In order to obtain analyses for the ethyl and isopropyl alcohol content of scrap iron, we utilized the method of gas chromatography. The Perkin-Elmer vapor fractometer, model 154, was used for these analyses. The column utilized for purposes of fractionation was Perkin-Elmer material F (tetramethylene glycol, dimethyl ether adsorbed on Celite). Sample size was 0.002 cc. Quantitation of the amounts of ethyl and isopropyl alcohols was obtained from standardization of the instrument against mixtures of these alcohols in water. Figure 1 illustrates a standard tracing; Figure 2 represents a tracing of a typical sample of scrap iron containing these alcohols.

Ten samples of scrap iron were subjected to gas chromatographic analysis for isopropyl and ethyl alcohol content. The isopropyl alcohol content was found to be 16.5, 14.6, 18.5, 16.7, 20.2, 15.0, 14.6, 17.5, 24.0, and 25.0% respectively. The ethyl alcohol content was found to be 36.5, 32.4, 46.7, 39.1, 23.0, 38.7, 33.9, 30.3, 32.2, and 34.4% respectively. The maximum error of the method was ±0.3%. All the samples were first analyzed qualitatively for the presence of isopropyl alcohol before being subjected to gas chromatography.

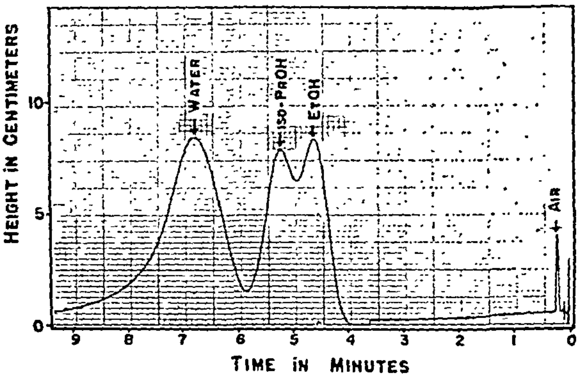

Fig. 1.—Standard tracing of the gas chromatograph of prepared mixture of ethyl alcohol (EtOH; 35%) and isopropyl alcohol (iso-PrOH; 25%) in water.

It may be suspected that the most frequently used utensils for the preparation of bootleg whiskey would be galvanized tubs, drums, tubing, etc., because of their relatively low cost and easy availability. During fermentation considerable amounts of acids are produced and may lead to the dissolving of zinc from the containers. Ten samples of scrap iron were subjected to a quantitative analysis for zinc content. For these analyses we modified and adapted the methods of Vallee and Gibson[5] and Hoch and Vallee.[6] The first method gave results of 3.64, 1.02, 1.16, 2.03, 5.14, 0.94, 4.21, 4.36, 1.54, and 2.76 mcg. per liter respectively. The second method gave results of 2.95, 1.22, 1.67, 2.12, 5.07, 1.21, 4.06, 4.09, 1.61, and 2.72 mcg. per liter respectively. The significance of these results is considered later.

Clinical Analysis of Fifty Patients with Scrap Iron Intoxication

The first 50 patients with scrap iron intoxication detected during a three-month period have been arbitrarily divided into five groups according to their predominant clinical picture. The largest group consisted of patients with acute brain syndrome as manifested by motor restlessness, hallucinations, illusions, extreme apprehension, tremor, and general disorientation. These symptoms, which are identical to those exhibited by a patient experiencing delirium tremens from ethyl alcohol, are usually reversible on abstinence from alcohol. There were 26 patients in this group, 15 of whom had complications. There was anemia due to iron deficiency in five, acetonuria (of five days' duration) in one, plastic rigidity in one, diarrhea (of 72 hours' duration) in one, latent syphilis in one, azotemia (with blood urea nitrogen level of 63 mg.%) in one, lobar pneumonia (not aspiration) in three, essential hypertension in one, and cellulitis in one. The average hospital stay was 8.6 days, and there were no deaths in this group.

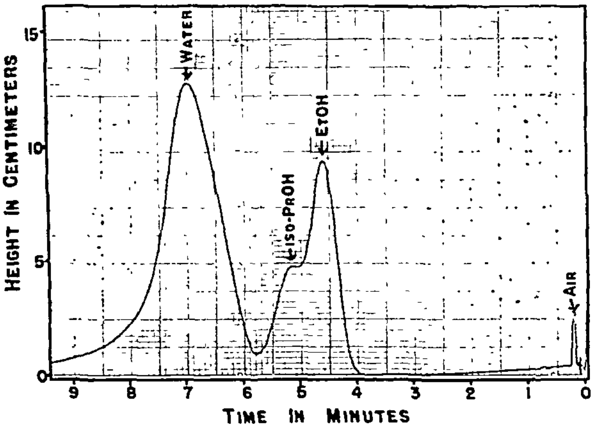

Fig. 2.—Tracing of the gas chromatograph of typical sample of "scrap iron" containing ethyl alcohol (EtOH; 38.7% calculated) and isopropyl alcohol (iso-PrOH; 15.0% calculated).

The second group consisted of five patients with a chronic brain syndrome, but there were irreversible mental changes. There were three patients with medical complications; of these, one had essential hypertension, one had anemia due to iron deficiency, and one had idiopathic epilepsy and anemia due to iron deficiency. Four patients had major psychiatric disturbances which required additional therapy. Two were schizophrenic, one catatonic, and the other paranoid; the third had a severe depressive reaction; the fourth had a case of concussion syndrome resulting from an automobile accident. Three of these four patients were discharged as improved. The catatonic schizophrenic patient died on the eighth hospital day after a pulmonary embolus. Permission for autopsy was refused.

Another group, the second largest, consisted of nine patients classified as having acute alcoholism. Though as a group their hospitalization period was short, their complications were the most severe. One patient fell prior to admission and dislocated the fourth cervical vertebra; this resulted in death on the fifth day in the hospital. Two patients were admitted in severe diabetic coma but recovered and were discharged as asymptomatic on insulin therapy. One patient had congestive heart failure secondary to a myocarditis, the etiology of which we were unable to determine; and, last, a patient in this group remained in the hospital 44 days to recover from an empyema secondary to a bronchopleural fistula.

In any group of alcoholics, gastritis and gastrointestinal disturbances are to be expected. We had two patients with severe gastritis with significant bleeding; one had a moderate hemorrhage and the other a massive hemorrhage. A third patient had a duodenal ulcer with massive hemorrhage. This patient's therapy was complicated by a platelet antigen-antibody reaction which resulted in further bleeding. Also, he had a five-day acute brain syndrome. All three patients were treated with a conservative medical regimen, and there were no deaths in this group.

Last, the most interesting group consisted of three patients admitted in hypoglycemic shock. They were admitted with blood sugar levels of 10 mg.%, 30 mg.%, and 33 mg.% respectively. After an acute episode of hypoglycemia, each of these patients was studied extensively for pancreatic and hepatic disturbances. Complete liver profile studies and cephalin flocculation, sulfobromophthalein retention, dye excretion, total and fractional protein level, prothrombin time, and glucose tolerance curve determinations were done. No abnormalities were found. Although we were familiar with the literature pertinent to hypoglycemia associated with bootleg whiskey, we did not suspect Solox (a shellac and paint solvent consisting primarily of ethyl alcohol and methanol) as the toxic agent, because the patients denied the ingestion of this fluid, and we were unable to detect methanol in either the blood or urine. However, one year later we were able to trace a similar case of hypoglycemia to Solox ingestion because of the telltale presence of methanol in the urine and blood of this individual. Undoubtedly these first three cases of hypoglycemia were likewise due to consumption of Solox. This emphasizes the point originally shown by Tucker and Porter[7] that the hypoglycemic effect of Solox is delayed. In our first three patients the metabolism of the methyl alcohol component of Solox was completed before the hypoglycemia occurred. This experience also illustrates the time-honored maxim that bootleg whiskey is often a mixture.

Toxicity

We were rather surprised at the scarcity of articles pertaining to case reports, toxicology, and symptoms of isopropyl and/or nephthalene poisoning in adults. The following symptoms and signs were compiled from several books on toxicology. Ingestion of isopropyl alcohol[8] results in dizziness, nervous and muscular disturbances, headache, marked fall in blood pressure, gastrointestinal hemorrhages, hypotension, shock, coma, uremia, and anemia. Ingestion of naphthalene[9] results in gastrointestinal irritation, diarrhea, liver and kidney damage, anemia, depression, convulsions, jaundice, and coma. No mention of the frequency of toxic psychosis was found in the articles that we reviewed, but in this series of 50 patients a significant majority exhibited definite symptoms of an acute or chronic brain syndrome out of proportion to the quantity of alcohol consumed.

More literature relevant to the toxic effects of naphthalene was found than articles reporting isopropyl alcohol toxicity. It is repeatedly emphasized in the literature that there is an individual susceptibility toward the toxic effects of naphthalene. Fifty years ago this product was frequently prescribed for the treatment of certain enteric fevers, namely typhoid, with only an occasional severe side-effect being recorded. The majority of the case reports relating to the toxic effect of naphthalene were concerned with the cumulative effect of naphthalene and the subsequent course of the patient who experienced a hemolytic anemia. Heretofore this has been reported primarily in children.

Smillie[10] reported four cases (three adults and one 10-year-old boy) of severe hemolytic anemia with the use of beta-naphthol for therapy of intestinal ancylostomiasis (hookworm) and concluded that it represented an individual susceptibility to the drug. In a report by McGregor,[11] we found references to three other cases of hemolytic anemia in adults, associated with the ingestion of moth balls. We had two such cases (to be reported in a later paper) not included in our first 50 cases. The hemolytic anemia was manifested by normochromic normocytic anemia with jaundice and elevated bilirubin and increased urobilinogen levels. Both patients reverted to normal on iron therapy and abstinence from scrap iron. Although we did not conclusively prove naphthalene, rather than isopropyl alcohol, as the toxin by challenge dosages of naphthalene, it is a fair assumption on the basis of these previous reports and the demonstration of beta-naphthol in their urine. The mechanism of this acquired hemolytic anemia is thought to be a congenital defect of glutathione in the red blood cells.[12]

Burning sensation in the urethra on urination was reported in the literature; however, this symptom was not obtained from any of our patients whose urine was positive for naphthalene. No gross or persistent microscopic hematuria which would suggest genitourinary pathology was noted in our series. Although the duration of the ingestion of scrap iron could not be determined in our patients, these latter two ascribed symptoms have been found mainly in people who have had prolonged contact with naphthalene. Likewise the known carcinogenic peculiarity of bladder cancer is known to exist only in workers in moth ball factories—we had no such cases.

McCord and associates,[13] in 1948, reported three cases of isopropyl alcohol intoxication and a review of the literature in regard to its toxic effects and reported: "Little is known about the effect of isopropyl upon the human individual other than some reports in the German literature in which small amounts of alcohol were taken experimentally by mouth." We did not notice the bradycardia or fall in blood pressure which has been reported, but rather an elevation of blood pressure and tachycardia. These two symptoms may be related to the delirium which many of the patients were experiencing at time of admission to the hospital. Animal experiments have shown that isopropyl alcohol is approximately twice as toxic in all respects as ethyl alcohol.[14] This was borne out in our case histories. Few patients were able to ingest more than one-half pint of scrap iron in six to eight hours and remain conscious. Only chronic alcoholics could drink as much as one pint and remain conscious. As reported by McCord and associates,[13] the blood level of isopropyl alcohol for drunkenness is 0.050 Gm.% and coma at 0.075 Gm.% in contrast to that of ethyl alcohol, which is more than twice these values.

We were able to find in the literature one case of isopropyl alcohol ingestion in an adult. The clinical picture was similar to that in our cases of acute brain syndrome, but the patient had the additional complications of lower nephron nephrosis which responded rather quickly to a conservative medical regimen. Our one case of azotemia (blood urea nitrogen level, 63 mg.%) was secondary to dehydration and responded quickly to hydration.

It was suggested that the metallic taste of scrap iron might represent the presence of zinc in a significant quantity; however, the amount found in representative samples of this fluid is comparable to the quantity present in the local drinking water. There were no symptoms which could be attributed to zinc toxicity alone. The metallic taste is probably caused by the strong concentration of alcohols and, perhaps, heavy metals in trace quantities.

Isopropyl alcohol is thought to be converted in the liver largely into acetone, which is excreted as such by the lungs and kidneys. This was borne out in only one patient, who had acetonuria for four days, of the 50 patients who were known to have drunk moderate amounts of isopropyl alcohol.

Naphthalene likewise is broken down in the liver into beta-naphthol, phenol, and muconic acid. All are excreted by the kidneys.

There is nothing of significant note in the treatment of our patients. There was a subsidence of most of the symptoms in the patients with toxic psychoses within several days simply with supportive therapy consisting of use of fluids, vitamins, and sedation or tranquilizers.

Summary

A new term, hitherto unknown to us, has become prevalent among imbibers of other than legally obtained alcoholic beverages. This term is "scrap iron" and is named thus because of the peculiar metallic taste. The chief ingredients are isopropyl alcohol and naphthalene. It is felt that the consumption of this preparation could become more in evidence because of the cheapness (isopropyl alcohol recently being sold in a large store for nine cents a pint) and because of its intoxicating effect. The frequency of severe physical and mental symptomatology was reviewed. It is anticipated that prolonged drinking of "scrap iron" will produce qualitative and quantitative effects similar to those of ethanol but of a more severe degree in a shorter period of time. As yet we have not observed the cumulative effects of scrap iron in a patient. Further investigation is warranted into the toxic effects, and steps should be taken to hinder the sale of these toxic substances.

16 Lucas St. (Dr. Gadsden).

Dr. Peyton C. Teague assisted in performing the quantitative analyses of scrap iron in this study.

CLINICAL NOTES

ARTERIAL THROMBOSIS WITH GANGRENE AFTER USE OF PROMAZINE (SPARINE) HYDROCHLORIDE

Morton Opinsky, M.D., A. Frederick Serbin, M.D.
and
Joseph E. Rosenfeld, M.D., Hartford, Conn.

This paper is a report of two cases of unusual and remarkably similar complications resulting from intravenous injection of promazine (Sparine) hydrochloride. Promazine, a phenothiazine derivative, is recommended in treatment of anxiety states, somatic disturbance, alcoholic syndromes, drug addiction, psychosis, manic depressive states, and schizophrenia.

Many side-reactions have been reported with its use, some mild and some severe. Untoward and catastrophic vascular complications in the two patients with alcoholism reported on here followed intravenous injection of this drug.

Lemere,[1] in 1950, warned that further observations are needed to establish the exact role of promazine therapy in intoxicated alcoholics. He reported that in one patient, after several intramuscular injections, promazine caused such a severe local reaction, with marked inflammation and induration at the site of injection, that its use had to be discontinued. He also reported three instances of convulsions after intramuscular administration of promazine in severely intoxicated patients. He felt at that time that these convulsions may have been either simply coincidental effects of withdrawal of alcohol or results of inadequately sustained tranquilization from two widely spaced subsequent doses of promazine. He also stated that other alcoholics refused to accept further intramuscular medication with promazine during the initial sobering up phases of their treatment because it made them worse.

In this report of two cases of vascular complication after intramuscular injection of promazine, it would seem more than coincidence that two cases so parallel in symptoms should follow each other within a few weeks. When the millions of intravenous injections of drug solutions that are given each year without mishap are considered, it is significant that two cases of arterial thrombosis after the use of the same drug can be reported from one community. For this reason, these experiences are related so that caution may be observed in the further use of promazine. In both cases, promazine was used for its tranquilizing effects after the heavy use of alcohol.

Report of Cases

CASE 1.—A 37-year-old woman was given 25 mg. of promazine in the left antecubital vein for tranquilization after the heavy use of alcohol. The patient was uncooperative and in a state of extreme agitation. After the needle had penetrated the vein and a small amount of promazine had been given, she jumped and then complained of severe pain in her hand and fingers. The needle was withdrawn, and her fingers and hand became cyanotic. She complained of intense pain at the site of injection. Immediately, procaine hydrochloride was injected into this site to alleviate the local pain. The pain, however, persisted, and stellate ganglion blocks were performed without relief of cyanosis or pain. Within a few days all the fingers of her left hand gradually became mumified, and dry gangrene ensued. This extended to the flexion crease of the wrist. No pulses were present at the elbow or the wrist. Four weeks later, on Dec. 19, 1956, an exploration of the antecubital fossa was done and the terminal portion of the brachial artery was found to be markedly constricted and of ropy consistency. It was totally occluded for a distance of 1½ in. There were no pulses through the cord-like structure, but, when the artery was opened, there was a slight flow of blood coming back through the radial and ulnar arteries. A polyethylene interval graft was inserted at the distal end of the viable brachial artery. This did not alter the clinical appearance of the hand. On Dec. 26, 1956, an amputation through the lower third of the forearm was performed. There was little bleeding, except for a weak flow through the dorsal interosseous artery. The wound healed subsequently without further complication. The patient continued to do well except for some pain in the arm stump; this pain ultimately subsided.

CASE 2.—A man, aged 28, was seen on Feb. 2, 1957, at the McCook Memorial Hospital. He had been given an intravenous injection of 25 mg. of promazine approximately 48 hours previously. The injection was given in the antecubital vein of his left forearm. On receiving the injection, the patient was said to have moved and to complain of pain in his hand. He later showed cyanosis of the distal phalanx of the ring finger and coolness of the whole ring finger. There was much pain on movement of his finger. The remaining portion of the hand appeared normal. There were also several irregular cyanotic blotches extending down the volar aspect of the forearm, distal to the site of injection. The areas measured from about 4.5 cm. in the upper aspect of the arm to 1.5 cm. in the lower arm. These areas were very tender. A radial pulse was present and in good force. A brachial plexus block and stellate ganglion block were done, and the cyanosis in the finger and the blotchy areas on the forearm returned to a normal color. Immediately after these procedures, the ulnar pulse became weakly palpable. Exploration of the antecubital fossa in the region of the injection was done and an area of thrombosis, 2 cm. long, in the left ulnar artery was found. No site of perforation of the artery could be found. No grossly abnormal findings could be noted in tissues at the site of injection. The artery was opened, but the clot seemed to be closely adherent to the arterial wall and could not be removed easily; thus, it was decided to excise the ulnar artery at the thrombosed portion of the artery. All other arteries seemed patent. A periarterial neurectomy of the distal brachial artery and its branches was done. After the operation, cyanosis in the distal phalanx and the blotchy areas on the forearm became more pronounced. The patient was treated with continuous stellate ganglion blocks for several days without any change. Heparin was also given. Pain continued in the distal phalanx, with progressive gangrene, and partial amputation of the finger was done on March 4, 1957. The blotchy areas on the forearm broke down but eventually healed. Several months later, a left dorsal sympathectomy was done at another hospital for pain and coldness in the hand. After the sympathectomy the pain and coldness in the hand was relieved.

Summary

It is felt that the etiology of the arterial spasm and thrombosis in two alcoholic patients treated with promazine (Sparine) hydrochloride might well be due to infiltration of the promazine into the soft tissues or reflexly through vein irritation after the intravenous injection. Extension to branches of the brachial artery causing gangrene in the hand, as reported in the first case, and gangrene in the left ring finger, in the second case, may have been by this mechanism. It is suggested that promazine be used intravenously with caution or perhaps not at all via this route.

SUBUNGUAL HEMORRHAGE IN PAN WASHERS

PRELIMINARY REPORT

Peter I. Long Jr., M.D., Dayton, Ohio

A great many articles[1] have been written concerning the effect of soaps and detergents on the hands, especially since the widespread introduction of detergent cleansing agents. To my knowledge little information has been obtained on the effects of detergents on the nails and nail beds. Viecelli[2] reported a case of onycholysis on exposure to alkalies in 1936. My attention was directed to this matter by the occurrence of three cases of nail-bed disease in pan washers on the dietetic service of the Veterans Administration Center. The cases reported here varied in intensity from a mild soreness of the nails to extensive subungual hemorrhage.

Report of Cases

Case 1.—A 61-year-old male presented with the complaint of very sore and tender nails. Examination revealed numerous small hemorrhages under all the nails of both hands (fig. 1). The lesions were noted primarily under the distal two-thirds of each nail. The skin of the hands was dry, and there was erythema over the joints. A complete physical examination was normal. There were no hemorrhagic lesions elsewhere on the body. The laboratory findings were as follows: The white blood cell count was 5,700 per cubic millimeter, with 70% polymorphonuclear leukocytes, 24% lymphocytes, 5% monocytes, and 1% eosinophils. The red blood cell count was 4,800,000 per cubic millimeter, and the hemoglobin level was 12.8 Gm. per 100 cc. The patient's bleeding time was 1¼ minutes; the platelet count was normal. The coagulation time was 15 minutes, the prothrombin time 63%, Coombs' test negative, and the serology negative. The patient's chest x-ray was normal.

The man's history revealed that he had been employed for three weeks as a pan washer. His nails became sore during the second week of employment. There was no previous history of sensitivity to soaps or detergents, nor was there any familial history of blood dyscrasia.

These hemorrhages progressed to a point that paracentesis of one nail was necessary to relieve the pressure symptoms. Over a period of two months the lesions became chronic in nature and the distal portion of the nails was separated from the nail beds. However, no nails were lost, and the patient's nails healed on his removal from the pan-washing job.

Case 2.—This 65-year-old male came to the first-aid room for treatment of a minor laceration of his hand. During treatment, he complained that the fingernail of the right fourth finger was sore. Examination revealed a subungual hemorrhage beneath this nail (fig. 2*A* and *B*). He could not remember any trauma to the nail. In approximately one month's time the man was seen again, and a chronic lesion involving one-third of the nail had developed: The distal portion of the nail was separated from the nail bed. The nail itself was dark and brittle. A complete physical examination was normal. The man's history noted that he had been working as a dishwasher for a year but had been transferred to the pan-washing room two weeks prior to the onset of his nail trouble. The laboratory findings were as follows: The patient's white blood cell count was 7,300 per cubic millimeter, with 72% polymorphonuclear leukocytes, 20% lymphocytes, 7% monocytes, and 1% eosinophils. His blood coagulation time was 11 minutes, and his platelet count was normal. Coombs' test was negative. Results of serologic studies were negative. His chest x-ray was normal.

Case 3.—A 21-year-old male reported sore fingernails two weeks after being hired as a pan washer. There were numerous small hemorrhages under the distal one-third of the nails, and the nails were extremely tender on pressure (fig. 2*C*). The physical examination was otherwise normal. The laboratory findings were as follows. The white blood cell count was 5,750 per cubic millimeter, with 55% neutrophils, 29% lymphocytes, 12% monocytes, 2% eosinophils, and 2% basophils. The hemoglobin level was 13.2 Gm. per 100 cc., hematocrit was 44.5 vol. %. The patient's bleeding time was 2½ minutes; his coagulation time was 10 minutes; and his platelet count was normal. Coombs' test direct and indirect, was negative; the results of serologic studies were negative. His chest x-ray was normal.

Comment

At this institution there are three separate pan-washing rooms located in various sections of the hospital. In each of the pan-washing rooms the same water supply, detergents, and steel wool are used. The same types of utensils are used everywhere. During the interval between the discovery of the first and third patient, the type of detergent cleansing agent was changed from a powdered detergent to a liquid detergent. However, the lesions developed while each of the detergents were in use.

All three cases of subungual hemorrhage developed in one pan room. The only difference in the pan-washing procedure that could be discovered was that our three patients all used heavy rubber gloves while working. All other pan washers either wore no gloves or only light cotton gloves to protect their hands from the steel wool.

We observed the washing techniques of the patients and found that during the course of the washing each patient accumulated 50 to 175 cc. of the washing solution in their gloves. The pH of the washing solution in the sinks was tested on a standard pH meter, and it varied from 7.1 to 10. The water temperature varied from 100 to 112 F. In the gloves, the pH of the washing solution

---

From the Veterans Administration Center.

varied from 5.2 to 6.7. The glove solution temperature ranged from 100 to 104 F. Each patient was patch tested with each of the two detergent solutions and with rubber from the gloves without reaction.

The explanation of the mechanisms of these hemorrhages presents an interesting problem. Several factors stand out. First, the pan scrubbing is fairly traumatic, entailing a lot of hard scouring, and this would have a tendency to separate the nail from the nail bed, traumatizing the subungual tissue. Second, only the men who wore gloves developed this lesion although they demonstrated no sensitivity to rubber. Third, the pH of the washing solution trapped in the glove was more acid than that in the washing sinks. This may be accounted for by perspiration and the action of the keratin on the pH of the detergent solution as noted by Martin-Scott and Ramsay.[3]

It is interesting that only men who had been employed as pan washers for a short period of time developed these lesions. The fact that they were not accustomed to this type of labor may be an important factor.

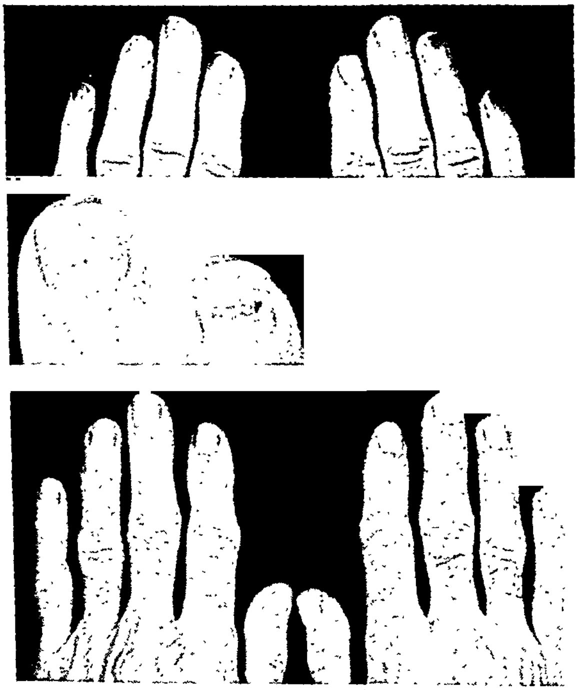

Fig. 1 (case 1).—*Top*, subungual hemmorrhage after three weeks' exposure to pan washing. *Middle*, maximum extent of disease. *Bottom*, four months after removal of patient from job as pan washer.

In determining the exact pathogenesis we must consider whether these lesions are purely traumatic or whether we are dealing with some toxic factor as well. Pure trauma seems unlikely since I feel the lesions would be more common if this were the circumstance. The change in the pH of the detergent solution trapped in the glove to the acid side may cause the breakdown of the detergent, with the subsequent release of a more irritating substance in the form of a sulfonic acid. This possibility is being investigated at the present time. Regardless of the exact pathogenesis, the subungual lesions I have described present a problem of medical and legal significance, since the cosmetic and functional impairment may be severe.

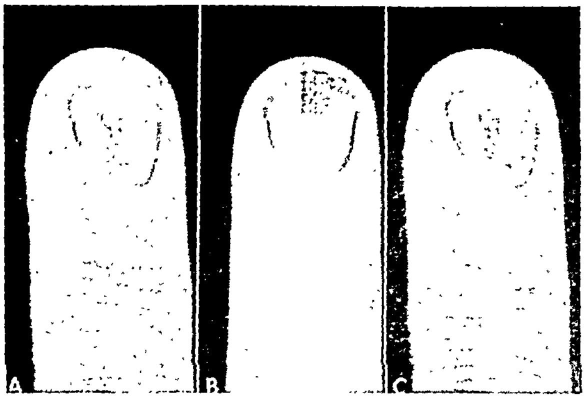

Fig. 2.—*A* (case 2), subungual hemorrhage limited to two nails of right hand. *B* (case 2), after three months' continued exposure to pan washing. *C* (case 3), small subungual hemorrhage after two weeks of pan washing.

Conclusions

Three patients had subungual hemorrhage. All of them were pan washers using detergents and rubber gloves in the washing process. The subungual hemorrhages subsided and the lesions completely cleared on removal of the patients from their jobs.

A change in the pH of the detergent solution trapped in the gloves and the trauma associated with scrubbing appeared to be the primary etiological factors. Further study is indicated to determine the exact pathogenesis. Prompt recognition of the lesions and elimination of the offending agent is necessary to prevent extensive nail bed damage.

MAMMARY CARCINOMA

WHEN a patient presents herself with a mammary carcinoma that has obviously metastasized distantly, or when recurrence with metastases occurs after mastectomy, treatment varies somewhat depending on whether the patient is in the age group from premenopausal up to 5 years postmenopausal, or more than 10 years postmenopausal, with a borderline or transitional period of about 5 years between. In the former group oophorectomy is recommended by many, but since this is only effective in 30 to 40% of patients Slaughter[3] recommends irradiation of localized metastases, particularly those in weight-bearing bones, which he claims is effective in about 90% of such patients. In almost 50% of these patients the tumor is hormone-dependent[4] and in most of this group after ovarian ablation a remission averaging about nine months is observed. If there is no response to oophorectomy the patient probably will not respond to adrenalectomy, but in patients with hormone-dependent cancer adrenalectomy may result in a second remission of about the same average duration.

Because the results after oophorectomy and adrenalectomy are usually short-lived, attempts have been made to get the same results without operation,[9] but so far the achievement of "medical adrenalectomy" has not been realized. Subjective improvement after the giving of prednisone or prednisolone is often dramatic but rarely prolonged. The drugs are especially useful in getting patients in better condition for oophorectomy or adrenalectomy, and in treating patients with cerebral metastases, hypercalcemia, and lymphedema.[4] Objective evidence of improvement after this form of treatment has been observed in electroencephalograms in patients with cerebral metastases.[6] Kennedy[10] found that fluoxymesterone is as effective as testosterone and has the advantage that it can be given by mouth. If in the latter group there is no response, they switch to estrogens and in the frankly postmenopausal group they give estrogens routinely.

One other form of endocrine ablation, hypophysectomy, has been used as a last resort. This heroic procedure is most successful in patients with hormone-dependent tumors but it is definitely contraindicated in fragile old women worn out by long-continued x-ray and hormonal treatment. Other contraindications are a history of cardiovascular disease, multiple painful rib fractures, massive pulmonary metastases, respiratory paralysis due to cord lesions, and evidence of hepatic insufficiency or renal damage in some patients. Lawrence[11] describes a procedure whereby pituitary activity can be abolished by proton irradiation. Patients so treated had remissions lasting as long as 20 months. Illingsworth[12] states that the results from adrenalectomy and hypophysectomy are not significantly different. Adrenalectomy is technically a much simpler procedure. Proper selection of patients for either operation is still difficult. After any type of endocrine ablation relapses occur. This is interpreted to mean that aberrant endocrine cells not removed at operation have undergone a compensatory hypertrophy or that the cancer is composed of a mixture of cell types of varying hormonal dependence and that after suppression of the hormone-dependent cells the hormone-independent cells continued to grow. He concludes that endocrine treatment should be tried earlier in the course of the disease than has been the practice.

In discussing chemotherapeutic agents for mammary carcinoma Taylor[13] states that conclusions as to their value are fraught with uncertainty because of the variable natural course of the disease, variations in the selection and size of samples used by different observers, the difficulty of measuring regression of the disease objectively, and the difficulty of attributing regressions to the procedure being tested rather than to late effects of the previous treatment or other factors. He based this particularly on the inconclusive results of treatment with

triethylenethiophosphoramide (Thio-TEPA). More recently Moore and Pickren[14] reported that a few months of palliation may be obtained by using triethylenethiophosphoramide. The chief importance of this observation is that it serves to keep up interest in chemotherapeutic research. It is hoped that a derivative or closely related preparation will be found that will surpass any chemotherapeutic agent used thus far.

The diagnosis of mammary carcinoma at an early stage still offers the best prognosis. Although in patients with this disease the die is largely cast by the tumor-host relationship which determines the number of patients curable by any form of treatment, the patient should be given the benefits of the best treatment available. As in few other forms of cancer, treatment must be individualized. A fixed plan of treatment is the refuge of the intellectually destitute.

DUMPING SYNDROME

One of the most unpleasant sequelae of gastric surgery is the complex physiological response to the presence of undigested food in the jejunum commonly called the dumping syndrome. It plays a role in postoperative weight loss and is a major factor in patients' dissatisfaction with the results of gastrectomy. Much confusion has arisen over the exact diagnostic criteria of this syndrome. Everson and co-workers[1] consider it a vasomotor phenomenon characterized by weakness, sweating, or dizziness. If any one of these symptoms occurs during or within one hour after eating, a positive diagnosis can be made. Although some authors speak of the nausea and vomiting that often accompany the syndrome these symptoms are an unreliable indication of true dumping syndrome.

According to Jordan[2] the incidence of the syndrome varies from 2 to 45% of patients who have undergone some type of subtotal gastrectomy. He attributes this discrepancy to the fact that those whose symptoms depend on the ingestion of certain foods may be erroneously diagnosed as having a food intolerance rather than dumping syndrome. Everson states that if only severe symptoms are considered the incidence is low and may even approach zero in some series. If on the other hand patients whose only symptoms are epigastric fulness and nausea are included an erroneous incidence approaching 100% may be reported. The fact that leading questions must be asked, because even patients with true dumping syndrome often do not complain of their symptoms, makes it hard to arrive at an accurate estimation of the incidence. Jordan believes that only about 15% have symptoms of sufficient severity to require treatment. No clear-cut increase in the incidence of dumping syndrome was found to be associated with an increase in the proportionate amount of stomach resected but the incidence did decrease with the elapsed time after operation. In other words many patients adjusted to their symptoms in time so that even though the symptoms did not disappear they became less troublesome.

Theories as to the underlying cause of dumping syndrome can be divided into mechanical and physiological.[3] According to the first, rapid emptying of the stomach causes symptoms by overdistending the jejunum. The weight of the distended jejunum causes traction on the stomach and this may be an added factor. Operative procedures with these factors in mind have been tried and good results have been reported by enthusiasts but the fact that dumping syndrome may be observed in the absence of these factors would indicate that they are at least not the sole cause. Suggested physiological factors that may cause dumping syndrome include hypoglycemia, sideropenia, altered digestion of fats, adrenal stimulation, fall in serum potassium level, and a drop in blood volume. No proof that any of these is the true cause has yet been produced. Webber and co-workers[3] found that in most patients with dumping syndrome there is a decrease in both blood volume and the potassium level but no correlation between this and the patient's symptoms was observed. Poth[4] states that dumping syndrome can be induced in anyone by introducing a large enough amount of hypertonic solution into a large enough portion of the small intestine and that the symptoms are not due primarily to distention but rather to depletion of extracellular fluids. Although the symptoms of dumping syndrome are almost identical with those of hypoglycemia the time relation to food taking is different. Hypoglycemic symptoms do not occur until two to four hours after eating.

The treatment of this condition was recently discussed in these pages by Jordan. Failure to control the symptoms by the use of a judicious diet, avoidance of fluids at meal times, rest after meals when convenient, and parasympatholytic drugs is rare. Although fluids should not be taken with the meals, as soon as symptoms occur the patient should drink 250 to 500 cc. of any fluid containing no sugar or electrolytes. Poth believes that gastrectomy should be combined with the construction of a gastric pouch (using a portion of the jejunum) of sufficient volume to act as a reservoir. His patients have not been followed long enough for the final outcome to be evaluated but the results judged by a short-term follow-up appear promising. In any case an increase in the knowledge of the pathogenesis of this condition should provide leads for further improvement in present methods of treatment.

ORGANIZATION SECTION

PRELIMINARY GUIDE FOR MEASURING WORK ABSENCE DUE TO ILLNESS AND INJURY

The following Preliminary Guide for Measuring Work Absence due to Illness and Injury has been prepared by the Committee on Medical Care for Industrial Workers, a joint committee of the Council on Medical Service and the Council on Industrial Health, for those physicians who are concerned with this problem in their practice of medicine. Reprints of this article are available on request either to the Council on Medical Service or the Council on Industrial Health. It is the hope of the two councils that physicians who are dealing with various aspects of the problem of work absence will review this guide and submit any suggestions they may have for its future revision.

The subject of work absence among the employed population has occasioned considerable concern in medical, management, labor, and government circles and in various community organizations. Over the years, an appreciable body of literature has been developed in the United States dealing with medical, economic, and sociological aspects of this problem. Each such contribution, while helping to explain the nature of segments of the problem has, at the same time, led to some confusion through presenting differing definitions, measurements, and attitudes towards absence.

In an effort to delineate one of the most important areas of work absence, namely, absence due to illness—whether confirmed by the physician or not—and injury (hereinafter referred to as "sick absence"), the Committee on Medical Care for Industrial Workers, a joint committee of the Councils on Medical Service and Industrial Health of the American Medical Association, has drawn upon many resources to develop recommended guides for defining and measuring such morbidity absence. The use of uniform definitions and measurements in the maintenance of sick absence records will insure comparability of such records not only within a given industry from one period of time to another, but also between different industries. It is hoped that all health personnel engaged in the collection of such data and management will adopt the Committee's recommendations so that a clearer recognition of sick absence and a more accurate evaluation of its real impact upon industry and the employed population may result.

The Committee on Medical Care for Industrial Workers recognizes that established company practices may, in some instances, present an obstacle to the adoption of these preliminary guides. It is convinced, however, that uniform information such as that called for in this guide, and in forms based thereon, can be secured as well as such additional information as individual companies feel is necessary. Future experience will determine the extent to which this guide should be modified, and how the information gathered over a period of time among many industries can best be compared and put to practical use.

Identifying and Measuring Work Absence

Definition.—An employee absent from work should be considered to be on "sick absence" when the reason for absence is his or her own illness or injury. The total duration of such an absence is to be considered as "sick absence" and recorded accordingly. The practice is to be discouraged of giving to an absence, which by this definition is sick absence, some such label as "annual leave," "administrative leave," or "leave without pay," after the absence has exceeded a specified number of days, in order thereby to avoid the recording of this as a sick absence. Maternity leave should not be classified as sick absence, except when complications increase the normal maternity leave.

Classification.—The definition recommended is based upon a distinction between absences due to, and those not due to, illness or injury. Sick absence, i. e., that due to illness or injury, is further classified as non-occupational or occupational in origin. An occupational sick absence is one that arises out of and in the course of employment.

Classification Divisions.—Classification divisions are (*a*) nonoccupational illness, (*b*) nonoccupational injury, (*c*) occupational illness, and (*d*) occupational injury.

Basic Measures of Sick Absence.—Severity rate, frequency rate, and disability rate (all defined below) are the three measures which have been selected to promote uniformity in the collection, recording, and interpretation of sick absence statistics. Although other measures are in use and utilized for different purposes and reasons by various companies, the use of these three measures is recommended as standard practice. The Committee further recommends, for denoting duration of absence, the use of calendar days rather than "scheduled days" or work days," since calendar days in industrial usage is nearer the correct duration of disability from an illness or injury. This is in line with the practice used in connection with sickness disability benefit payments, and in sickness surveys conducted among the general population.

Severity Rate: Severity rate is defined as the number of calendar days lost per absence. The formula is as follows:

$$\frac{\text{No. of calendar days of absence due to nonoccupational illness (or injury)}}{\text{No. of absences due to nonoccupational illness (or injury)}}$$

Frequency Rate: Frequency rate is defined as the number of absences per 1,000 employees per unit of time (month or year). The formula is as follows:

$$\frac{\text{No. of absences due to nonoccupational illness (or injury) per month or year}}{\text{Av. no. of employees on payroll}}$$

It is recommended that "average number of employees" be arrived at by taking an average of the totals of employees on the first and final pay days of the month.

Disability Rate: Disability rate is defined as the number of calendar days lost per employee per unit of time (month or year). The formula is as follows:

$$\frac{\text{No. of calendar days of absence due to nonoccupational illness (or injury) per month or year}}{\text{Av. no. of employees on payroll}}$$

$$\text{Disability Rate} = \frac{\text{Frequency Rate} \times \text{Severity Rate}}{1{,}000}$$

Note: Another method to compute frequency and severity rates for occupational injuries is that recommended by the National Safety Council. The Frequency Rate is the number of disabling work injuries per million employee-hours of exposure. The Severity Rate is the total days charged for work injuries per million employee-hours of exposure.

Diagnosis and Diagnosis Groupings.—It is recognized that one of the basic problems in collecting information will be the classification of illness and injury. The American Medical Association has played an important role over the past 25 years in developing and revising "The Standard Nomenclature of Diseases and Operations," and in recommending that it be used as the basic reference source for proper terminology of clinical diagnoses. The Standard Nomenclature is a classification of accepted terminology in use by the majority of hospitals in the United States for diseases and operation index filing. It is presently undergoing a major revision so that it can be used as a clinical-statistical classification when completed. The Committee is therefore not recommending the establishment of, or adherence to, any specific groupings at this time but plans to recommend the use of Standard Nomenclature categories when the revision is completed and made available to all physicians.

Records.—An infinite variety of forms could be devised and made to serve to record the essential information. These range from spread-sheet to punch card systems. Since another committee of the American Medical Association has the responsibility for developing suggested record-keeping forms, the Committee on Medical Care for Industrial Workers is merely noting at this time the various types of data which should be called for in such forms. Physicians and others responsible for the compilation and analysis of morbidity data are invited to submit the results of their analyses, together with copies of forms developed, to the Committee for possible future publication.

The items in the table are among those suggested for inclusion in sick absence records in individual and/or consolidated (group) records and reports. They do not preclude the addition of other items considered necessary by individual physicians or companies for other types of analyses.

Some Items Suggested for Inclusion in Sick Absence Records

- Name or identifying number
- Sex
- Marital status
- Department
- Occupation (see text, Appendix A, for definitions
  - Salaried
    - Managerial and supervisory
    - Clerical and sales
  - Production (hourly)
    - Semi-skilled and unskilled
    - Skilled
- Length of service with company (yr.)
  - Less than 1
  - 1- 4
  - 5- 9
  - 10-14
  - 15-19
  - 20-24
  - 25 and over
- Date of beginning of absence
- Date of return to work or other termination
- Duration of absence in calendar days
- Date of birth
- Age group (yr.)
  - Under 25
  - 25-34
  - 35-44
  - 45-54
  - 55-64
  - 65 and over
- Diagnosis
  - (Standard Nomenclature, 5th Edition—in preparation)
- Classification
  - Nonoccupational illness
  - Nonoccupational injury
  - Occupational illness
  - Occupational injury
- Number of days of paid sick leave allowed
- Calendar days of absence (days)
  - 1
  - 2
  - 3
  - 4- 7
  - 8- 14
  - 15- 28
  - 29- 49
  - 50- 91
  - 92-182
  - 183 and over
- Reason for termination
  - Returned to work
  - Discharged
  - Resigned
  - Retired
  - Deceased

Some Rules to Be Observed.—(*a*) The same person may be involved in more than one absence in the course of a month or a year. Therefore, it is important to record not only the total number of absences but also the actual number of people involved. (*b*) Where more than one diagnosis is involved in an absence, the absence and all calendar days lost should be attributed to the diagnosis associated with the condition causing the greatest loss of days. (*c*) Each absence caused by an acute illness or an acute episode in the course of a chronic illness is to be considered as a separate absence. However, a person who returns to work before he has fully recovered from an acute illness or an acute episode in the course of a chronic illness and who consequently has to be absent again, should be considered as having had one continuous absence instead of two absences. The determination as to whether recovery from an acute illness, or an acute episode in the course of a chronic illness is incomplete, is one to be made according to individual company practice and medical judgment. (*d*) To facilitate record keeping and to avoid counting as two or more absences an absence which begins in one reporting period and continues into and through a subsequent reporting period(s), the arbitrary rule will be that such an absence will be charged against the reporting period in which it ends. Many organizations may find it difficult or undesirable to adhere to this rule, especially if they have been accustomed to computing absence data at the end of each calendar year. The reports of companies which wish to continue this practice should clearly indicate this fact, so that the basis for data compiled will be understood. (*e*) Where, upon operation of the rule stated in the first sentence of *d*., prolonged absence(s) would tend to exaggerate unduly the rate for any reporting period, the circumstances should be explained in a footnote.

Records containing the foregoing items and condition of recording information will be able to provide uniform data for the (1) three basic measures of absence, and, (2) various relationships involving age, occupation, sex, length of employment, and other factors considered of interest and importance.

Appendix A

Definitions of Occupations. Definitions of occupations (see table) are as follows:

Managerial and Supervisory: Managerial and supervisory classification includes officers of company, department managers, supervisors, and foremen. This category also includes technical and professional staff personnel such as accountants, auditors, editors, engineers, lawyers, physicians, nurses, and statisticians. These occupations include all those responsible for policy-making, planning, advising, coordinating, or guiding the work of others.

Clerical and Sales: Clerical and sales classification includes all nonsupervisory office personnel and those performing clerical duties such as shipping and receiving clerks, and stock clerks. This category also includes sales personnel such as canvassers, solicitors, demonstrators, and shoppers.

Skilled: Skilled classification includes craft and manual operations requiring a thorough and comprehensive knowledge of the processes involved in the work, the exercise of considerable independent judgment, a high degree of manual dexterity and, often, responsibility for valuable equipment and product. This group of workers becomes qualified by serving apprenticeships or extensive training periods.

Semi-skilled and Unskilled: Semi-skilled and unskilled classification includes all other production or hourly paid workers or service personnel not included in the previous classifications.

MEDICAL SCHOOL AND PRACTICE LIAISON

The A. M. A. Board of Trustees has endorsed the creation of a four-way liaison committee to bring about closer relationships between medical education and the practice of medicine. The group will be comprised of two members of the Board of Trustees, two presidents of universities having medical schools, two representatives of the Council on Medical Education and Hospitals, two designates of the Association of American Medical Colleges, and respective staff members.

Names of committee members were not immediately announced, pending final decision on selection by all groups concerned. Unlike the special committee formed early this year to mediate differences between some medical educators and some medical practitioners in Georgia (see editorial, "Concord Out of Conflict," The Journal, Aug. 30, 1958, page 2206) the new committee is not designed to help solve an existing local problem but, rather, to function on a long-range basis—building rapport and nipping incipient problems before they arise.

NEW EDITION OF AMERICAN MEDICAL DIRECTORY AVAILABLE

The new 20th edition of the American Medical Directory, which gives brief professional data about 250,621 physicians in the United States and Canada, is now available. The directory lists for each physician his age, address, date of licensure, specialty, and membership in special medical societies.

This edition contains 18,398 new names of physicians that did not appear in the last previous edition (1956) of the directory and also the names of 1,214 physicians whose addresses are unknown. The states with the biggest gains include California, 1,467; Florida, 476; Michigan, 395; Ohio, 324; Washington, 136; Oregon, 84; Arizona, 70. Among those in the loss column are Minnesota, 50; Iowa, 33; Missouri, 31.

Single copies of the directory sent anywhere in the United States or its possessions cost $35, and to other countries the cost is $38. Orders may be sent to these headquarters.

JOINT CONFERENCE COMMITTEES

Noting that joint and separate responsibilities which doctors and hospitals have in providing medical care and hospital services "cannot be discharged effectively without proper liaison," The A. M. A. Board of Trustees and the American Hospital Association's Board of Trustees have endorsed a recommendation that every hospital set up a Joint Conference Committee made up of representatives from its medical staff and its administrative staff. The recommendation first was made last February in a statement by the A. M. A. Council on Medical Education and Hospitals. Such committees are necessary, according to a preamble of the statement, because "they will bring to bear on major decisions which must be made in the hospital a full measure of broad experience, intelligence and responsibility. . . . There should be a common ground where these two groups can meet in order that there may be a mutual understanding of each other's activities and problems as the art and science of medicine become more complex and more comprehensive."

World Medical Association at Copenhagen

Scenes from 12th Assembly, Aug. 15-29, 1958

A, W.M.A. officials applaud address of welcome to Copenhagen. *Left to right* are Secretary General Louis H. Bauer, retiring President Ahmet Rasin Onat of Turkey, Council Chairman L. G. Tornal of Spain, and W.M.A. Journal Associate Editor S. S. B. Gilder of Canada. *B,* A. Lawrence Abel *(left),* who presented medical film on "Hemorrhoids and the Early Detection of Rectal Cancer," is congratulated by Denmark's Prime Minister Hans Christian Hansen. Dr. John Henderson *(center),* Medical Director of Johnson & Johnson, delivered keynote address. *C,* Dr. Louis H. Bauer *(left),* Secretary General of the W.M.A., and Dr. Gunnar Gundersen *(second from left),* President of the A.M.A., congratulate Dr. Charles Jacobsen *(far right)* on his election as President of W.M.A. Looking on is Hans Christian Hansen. *D,* Dr. Malcolm R. Hill, of Los Angeles, presents his film, "Anorectal and Sigmoidoscopic Examination with Differential Diagnosis." *E, Left to right* are A.M.A. President-elect Louis M. Orr, who delivered scientific paper on "The Biological Effects of Nuclear Radiation"; A.M.A. President Gunnar Gundersen; and A.M.A. Executive Vice-president F. J. L. Blasingame. *F,* Two Japanese physicians congratulate A.M.A.'s Mr. Ralph P. Creer on International Medical Film Exhibit. At *left* is Dr. Tomio Ogata of Tokyo, Vice-president of the General Assembly of Japanese Medical Congress. At *center* is Hiroshi Ishii of Tokyo, Supervisor of the Japanese Medical Association.

COMMITTEE ON INFLUENZA

In the fall of 1957 the A. M. A. Special Committee on Influenza cooperated with state medical societies, the U. S. Public Health Service, and other medical and health groups in the initiation and operation of mass immunization programs designed to combat the spread of Asian influenza. While there is no present threat of another Asian influenza epidemic, there is a continuing necessity for the immunization of certain groups and individuals. Therefore, the Committee believes that the following recent announcement by the U. S. Public Health Service is of interest to all physicians.

FRANK W. BARTON, *Secretary.*

INFLUENZA VACCINATION

The Public Health Service has recommended consideration of influenza vaccination among groups wishing to guard against absenteeism in their professions or occupations, and among those to whom the disease might be an added health risk. The Service pointed out that there are now ample supplies of influenza vaccine of the polyvalent type, containing immunizing material against the important strains of influenza, including the Asian strain, and that vaccination should be planned before the fall season begins. Dr. Leroy E. Burney, surgeon general of the Public Health Service, said that while there is no indication at present that widespread attacks of influenza will occur this fall and winter there undoubtedly will be some influenza and that vaccination is a prudent measure for certain groups and individuals.

Dr. Burney stressed that practicing physicians should be the judges of whether or not to vaccinate individuals. He said groups which should be considered for vaccination include hospital staffs whose services are necessary to the care of the sick; groups living in close proximity where influenza could spread rapidly, such as institutions; industrial or service groups, big or small, in occupations where the sudden absence of a sizable part of the force would create serious disruption of the work; and individual patients or groups who have a special risk, such as the aged, the chronically ill, and pregnant women. This special risk group, Dr. Burney said, should be the special area of consideration for the private physician.

COUNCIL ON MEDICAL SERVICE

UNION HEALTH CENTERS, 1958 SURVEY

The Committee on Medical Care for Industrial Workers of the Council on Medical Service and the Council on Industrial Health has recently completed a third survey of union health centers. A forthcoming publication will contain descriptions of 29 such centers together with data on various aspects of their operations. (A previous announcement in THE JOURNAL gave the figure as 28. An additional plan has since been surveyed.) The 29 centers represent more than half of the 50 union health centers in operation which have an enrollment of approximately 950,000 union members and, in some instances, dependents.

Union health centers have emerged as a major development in the provision of medical care to members of unions only within the past 15 years. The earliest center was that of the International Ladies' Garment Workers' Union in New York City, which was organized in 1913. It was not until World War II, when the government's anti-inflation "hold-the-line" order virtually halted wage increases, that health and welfare plans became matters of prime importance in labor-management negotiations and collective bargaining. Medical services provided through these health centers range from diagnostic only to comprehensive medi-

---

Members of the Committee on Medical Care for Industrial Workers are Drs. Frank J. Holroyd, Chairman, Princeton, W. Va.; T. J. Danaher, Torrington, Conn.; Edwin P. Jordan, Charlottesville, Va.; Melvin N. Newquist, New York; Leo Price, New York; William A. Sawyer, Rochester, N. Y.; Frederick W. Slobe, Chicago; Clyde C. Sparks, Ashland, Ky.; Donald A. Dukelow, Consultant; Mr. Edwin J. Holman, Consultant; Dr. B. Dixon Holland, Secretary, Council on Industrial Health; Mr. George W. Cooley, Secretary, Council on Medical Service; and Mr. Murray Klutch, Research Associate, Chicago.

cal care, although "comprehensive" features vary according to the specific plan. Most health centers, however, provide diagnostic and ambulatory medical care through closed panels. Physicians are, for the most part, employed on an hourly or session basis, although a small number receive a salary or retainer for their services. In a few instances, physicians in private group practice contract to render the specific services negotiated through the contract between the union and the employer.

TABLE 1.—*Date of Origin, Membership, and Scope of Medical Programs of Twenty-nine Union Health Centers, 1958 Survey, Committee on Medical Care for Industrial Workers*[*]

Plan	Date Begun	Total Eligible	Total Members	Dependents Covered	No. of Locals Concerned	No. of Firms Concerned	Scope of Program
Amalgamated Clothing Workers of America[†]							
Chicago	1955	10,000	9,500	Spouses, retired members	N.A.[§]	Over 100	Diagnostic, ambulatory medical care
New York and New Jersey (Mobile Unit)	1957	3,000	3,000	None	1	57	Diagnostic only
New York	1951	33,356	33,356	Spouses	26	N.A.	Diagnostic, ambulatory medical care
Philadelphia	1951	23,000	23,000	Spouses	N.A.	Several hundred (tabulated as 300)	Diagnostic, ambulatory medical care
International Ladies' Garment Workers' Union							
Allentown, Pa.	1948	12,000[‡]	12,000	None	5	220	Diagnostic only
Boston	1949	15,000	15,000	None	52	N.A.	Diagnostic, ambulatory medical care
Chicago	1955	7,000	7,000	None	10	250	Diagnostic, ambulatory medical care
Cleveland	1952	5,000	5,000	None	13	N.A.	Diagnostic only
Harrisburg, Pa. (Mobile Unit)	1951	N.A.	N.A.	None	N.A.	75	Diagnostic only
Kansas City, Mo.	1950	2,562	2,562	None	9	40	Diagnostic, ambulatory medical care
Los Angeles	1951	9,441	9,441	None	14	230	Diagnostic, ambulatory medical care
Minneapolis	1950	800[‡]	800	None	5	18	Diagnostic, ambulatory medical care
Newark, N. J.	1951	30,000	30,000	None	34	617	Diagnostic only
New York	1913	155,000	155,000	Spouses, retired members, children under 18	32	N.A.	Diagnostic, ambulatory medical care
Philadelphia	1944	21,071	21,071	None	N.A.	N.A.	Diagnostic, ambulatory medical care
Springfield, Mass. (Mobile Unit)	1947	2,400	2,400	None	N.A.	17	Diagnostic only
Wilkes-Barre, Pa.	1948	21,566	21,566	None	5	256	Diagnostic only
Amalgamated Laundry Workers, New York	1954	18,000	16,000	Spouses and retired members, children for special programs	13	1,400	Diagnostic, ambulatory medical care
Amalgamated Lithographers of America, New York	1953	7,500	7,500	None	1	300	Diagnostic, ambulatory eye care
American Federation of Labor Medical Service Plan, Philadelphia	1951	52,000	32,000	Families of members	28	300	Diagnostic, ambulatory medical care
Building Service Employees (Local 32B) International Union, New York	1957	36,000	36,000	None	1	N.A.	Diagnostic, ambulatory medical care
Medical Department: Pension Committee of the Joint Industry Board of the Electrical Industry, New York	1953	7,000	7,000	None	1	N.A.	Diagnostic only
New York Hotel Trades Council and Hotel Association of New York City	1956	34,000	34,000	None (Retired members)	20	279	Diagnostic, ambulatory and in-hospital medical care
New York Shipping Association—International Longshoremen's Association (Ind.), Brooklyn	1957	40,000	12,000	None	N.A.	N.A.	Diagnostic only
Union Eye Care Center, Chicago	1951	92,734	92,734	Families (about 5%)	106	N.A.	Diagnostic, ambulatory eye care

Warehouse and Distribution Workers Union, Local 688, Labor Health Institute, St. Louis	1945	15,849	6,361	Families	1	200	Comprehensive medical care
Willys Unit, Local 12, UAW, Toledo	1955	155,463	155,463	Spouses and children	103	N.A.	Diagnostic only
Totals		830,166 (28 plans)	766,178 (28 plans)		489 (23 plans)	5,259 (19 plans)	10 Diagnostic only 17 Diagnostic, ambulatory medical care 2 Comprehensive

---

[*] Data as of Dec. 31, 1957, unless otherwise indicated. Plans arranged, for most part, according to union sponsorship; exact names of union health centers will be found in section of forthcoming publication describing each plan.

[†] Health centers are named Sidney Hillman.

[‡] 1952.

[§] N.A. = not available.

Table 1 is a listing of the 29 union health centers surveyed showing their dates of origin, eligible and actual membership, whether dependents and retired members are covered, the number of union locals involved in each program, and the scope of the medical program offered.

As previously indicated, the ILGWU Union Health Center in New York City is the oldest one in existence, having been organized in 1913. This union, incidentally, has the largest number of health centers throughout the United States. Of the remaining 28, 6 were begun prior to 1950, and the majority since then. The enrollment in 28 of the plans for which such information was available was over 765,000. This represents 80% of the estimated enrollment in all union health centers as of the end of 1957. Eleven plans, with an enrollment of approximately 530,000, included one or more dependents. Three of the 11 which covered dependents also included retired members; one other plan which did not include dependents also covered retired members. Of the 29 health center programs, 23 for which information was available were participated in by 489 local unions. In most cases, these locals are part of the union. In a few instances, such as the American Federation of Labor Medical Service Plan, the St. Louis Labor Health Institute and Willys Unit, Local 12, other unions may also affiliate with the plan. These are generally called multiunion programs. One of the characteristics of these union health centers is that their members usually, but not always, work in relatively small establishments or units which are widely separated and have little or no in-plant medical services or occupational health program. Over 5,200 firms were involved in the collectively bargained agreements supporting these centers of the 19 programs for which such information was made available. As previously indicated, most health centers provide diagnostic and ambulatory medical care. Of the 29 union health centers surveyed, 17 offer these medical services, 10 provide diagnostic programs only, and 2 offer a more or less comprehensive program.

TABLE 2.—*Personnel and Payment to Physicians in Twenty-nine Union Health Centers, 1958 Survey, Committee on Medical Care for Industrial Workers*

Plan	Administrative	Physicians	Nurses	Ancillary	Payment to Physicians (Exclusive of Medical Director)*
Amalgamated Clothing Workers of America					
Chicago	9	30	4	10	$9 per hr., 1st yr.; $9.50 per hr., 2d yr.; $[illegible] per hr., 3d yr.
New York and New Jersey (Mobile Unit)	4	3	1	4	Retainer
New York	22	77	7	15	$5.75 for general practitioners; $7.75 for specialists
Philadelphia	37	44	5	14	$7.00 per hr., 1st yr.; $8.50, 2d yr.; $10, thereafter
International Ladies' Garment Workers' Union					
Allentown, Pa.	6	24	2	2	$7 per hr.
Boston	6	35	3	4	$7 per hr.
Chicago	2	26	4	6	$8.50 per hr.
Cleveland	3	34	1	2	$20 per 2-hr. session
Harrisburg, Pa. (Mobile Unit)	2	31	4	4	$15 per 2½-hr. session
Kansas City, Mo.	1	31	4	3	$10 per hr., 1st 5 years; $11 thereafter
Los Angeles	9	39	5	6	$12 per hr.
Minneapolis	37	44	5	13	$7 per hr., 1st yr.; $8.50 per hr. 2d yr.; $10, thereafter
Newark, N. J.	2	23	5	9	$15 per 2-hr. session
New York	142	175	42	40	Salary and hourly‡

* Virtually all medical directors are on salary for their part-time or full-time employment.
† N.S. = not stated.
‡ $5.50-$10 per hr. Greatest number receive $6.50 per hr. Salaries of chiefs of services range from $3,000 to $8,000 per yr.

Table 2 is a breakdown of the personnel employed by the union health centers surveyed. Over 1,100 physicians are employed on a part-time basis (hourly or per session), and generally work at the center two or three days a week for periods of two or three hours. In some instances, these private practitioners work as many as 20 hours a week. Hourly rates for general practitioners range from $5.75 to $10 per hour; those for specialists range from $7 to $12 per hour. The 29 plans employ 161 nurses of various qualifications, and 242 auxiliary and ancillary personnel, including laboratory and x-ray technicians, social workers, and medical librarians.

Table 3.—*Number of Persons in Plan and Number Utilizing Union Health Centers, 1958 Survey, Committee on Medical Care for Industrial Workers**

Plan	No. of Persons in Plan	No. Utilizing Services	% of Persons Utilizing Services Over 1-Yr. Period†
Amalgamated Clothing Workers of America

* Data as of December, 1957, unless otherwise indicated.

† Percentage utilization computed on yearly basis where utilization is indicated for more or less than a 1-yr. period.

‡ One explanation for this figure is that it possibly includes all visits made to the plan by a member. The requests data on utilization did not ask for patient-visits.

Table 3 is concerned with the number and percentage of persons utilizing the health centers' services over a one-year period. Where utilization figures were made available for more or less than a one-year period, the percentages were computed on an annualized basis. Yearly utilization ranged from a low of 5.5% in one plan to a high of 89.2% (excluding the plan with the footnote explanation and the plan with incomplete enrollment information). Of the 27 plans, 2 had a utilization of less than 10%; in 5 plans utilization ranged from 10 to 20%; in 5 plans it ranged from 21 to 30%; in 11 plans it ranged from 31 to 50%; in 3 plans utilization ranged from 51 to 75%; and in one plan offering comprehensive medical care it was over 89%. It should be noted that these percentages are based on figures supplied by the plans. They may or may not be accurate inasmuch as there are no uniform criteria or definitions for recording various types of data among the administrators of these plans. The footnote of table 3 offers one explanation for possible overstatement of utilization rates. There are other explanations which may similarly affect such rates.

Table 4 indicates the sources and methods of financing of the 29 union health centers surveyed. Collective bargaining represents the primary source of monies for which support of the centers is received. Varying arrangements exist among different unions for allocating portions of its health and welfare benefits for the operation of their health centers. Contributions from management constitute the only source of support for 25 such programs.

the end of 1957. Eleven plans, with an enrollment of approximately 530,000, included one or more dependents. Three of the 11 which covered dependents also included retired members; one other plan which did not include dependents also covered retired members. Of the 29 health center programs, 23 for which information was available were participated in by 489 local unions. In most cases, these locals are part of the union. In a few instances, such as the American Federation of Labor Medical Service Plan, the St. Louis Labor Health Institute and Willys Unit, Local 12, other unions may also affiliate with the plan. These are generally called multi-union programs. One of the characteristics of these union health centers is that their members usually, but not always, work in relatively small establishments or units which are widely separated and have little or no in-plant medical services or occupational health program. Over 5,200 firms were involved in the collectively bargained agreements supporting these centers of the 19 programs for which such information was made available. As previously indicated, most health centers provide diagnostic and ambulatory medical care. Of the 29 union health centers surveyed, 17 offer these medical services, 10 provide diagnostic programs only, and 2 offer a more or less comprehensive program.

TABLE 2.—*Personnel and Payment to Physicians in Twenty-nine Union Health Centers, 1958 Survey, Committee on Medical Care for Industrial Workers*

Plan	Administrative	Physicians	Nurses	Ancillary	Payment to Physicians (Exclusive of Medical Director)*

* Data as of December, 1957, unless otherwise indicated.

† Percentage utilization computed on yearly basis where utilization is indicated for more or less than a 1-yr. period.

‡ One explanation for this figure is that it possibly includes all visits made to the plan by a member. The requests data on utilization did not ask for patient-visits.

Table 3 is concerned with the number and percentage of persons utilizing the health centers' services over a one-year period. Where utilization figures were made available for more or less than a one-year period, the percentages were computed on an annualized basis. Yearly utilization ranged from a low of 5.5% in one plan to a high of 89.2% (excluding the plan with the footnote explanation and the plan with incomplete enrollment information). Of the 27 plans, 2 had a utilization of less than 10%; in 5 plans utilization ranged from 10 to 20%; in 5 plans it ranged from 21 to 30%; in 11 plans it ranged from 31 to 50%; in 3 plans utilization ranged from 51 to 75%; and in one plan offering comprehensive medical care it was over 89%. It should be noted that these percentages are based on figures supplied by the plans. They may or may not be accurate inasmuch as there are no uniform criteria or definitions for recording various types of data among the administrators of these plans. The footnote of table 3 offers one explanation for possible overstatement of utilization rates. There are other explanations which may similarly affect such rates.

Table 4 indicates the sources and methods of financing of the 29 union health centers surveyed. Collective bargaining represents the primary source of monies for which support of the centers is received. Varying arrangements exist among different unions for allocating portions of its health and welfare benefits for the operation of their health centers. Contributions from management constitute the only source of support for 25 such programs.

In one case, the union finances the entire cost of the program, presumably from members' dues. In one program, union members are assessed an amount above and beyond the employers contributions. In one program patients' fees for service rendered support the program, although the unions involved purchase shares to join the program and assume responsibility for any deficit incurred. Another program is maintained by a combination of employer contributions, union fees and contributions, and fees for service to members.

The tables and text presented here contain some of the highlights of the forthcoming publication by the Committee on Medical Care for Industrial Workers. The 1958 survey treats each union health center as a specific case study, and for each plan includes information and data on (1) history; (2) membership; (3) objectives of programs; (4) facilities; (5) financing; (6) budget and operating costs; (7) administration; (8) business and professional personnel; (9) benefits; and (10) preventive aspects of the services.

TABLE 4.—*Source and Methods of Financing of Twenty-nine Union Health Centers, 1958 Survey, Committee on Medical Care for Industrial Workers*

Plan	Source	Method of Financing
Amalgamated Clothing Workers of America		
Chicago	collective bargaining	Employer contributions to Social Benefit Fund; fund allocated $2.60 per mo. per member in 1956 and 1957
New York and New Jersey (Mobile Unit)	collective bargaining	Portion of employer contribution to Sick Benefit Fund (not stated)
New York	collective bargaining	Employers contribute 0.25% of gross payroll for operations of center; members assessed $10 annually
Philadelphia	collective bargaining	Employers contribute 0.75-1% of payroll; members assessed $20 to start program
International Ladies' Garment Workers' Union		
Allentown, Pa.	collective bargaining	Employer contributes 2% of gross payroll for health and welfare benefits, part of which maintains center
Boston	collective bargaining	Employer contributes 6.5% of gross payroll for health and welfare benefits, 2% of which maintains center
Chicago	collective bargaining	Employer contributes 1% of gross payroll to trust fund; fund allocates $1 per mo. per member to center, and makes up any deficit
Cleveland	collective bargaining	Employer contributes 3.5% of gross payroll to Health Fund, part of which maintains center
Harrisburg, Pa. (Mobile Unit)	collective bargaining	Amount contributed by employers not stated
Kansas City, Mo.	collective bargaining	Employers contribute 1% of gross payroll
Los Angeles	collective bargaining	Employers contribute percentage of gross payroll, portion of which maintains center
Minneapolis	collective bargaining	Employers contribute 1% of gross payroll
Newark, N. J.	collective bargaining	Employers contribute percentage of gross payroll, portion of which maintains center
New York	collective bargaining	Employers contribute 3.5-5% of gross payroll, portion of which maintains center
Philadelphia	collective bargaining	Employers contribute 6-9% of gross payroll; center receives 0.5%
Springfield, Mass. (Mobile Unit)	collective bargaining	Employers' contributions (amount not stated)
Wilkes-Barre, Pa.	collective bargaining	Employers contribute 3.5-5% of gross payroll, 2% of which is allocated to the center
Amalgamated Laundry Workers, New York	collective bargaining	Employers contribute 3% of payroll, portion of which maintains center
Amalgamated Lithographers of America, New York	collective bargaining	Employers contribute $4 per wk. per employee to Sickness and Accident Fund; less than 10% of this supports the center
American Federation of Labor Medical Service Plan, Philadelphia	collective bargaining	Employers' contributions to first fund according to individual contracts; local unions assessed $15 per single member, $30 for couple, and $37.50 for family (including children up to 9 years of age) for operation of center
Building Service Employees (Local 32B) International Union, New York	Union finances entire cost of program	
Medical Department: Pension Committee of the Joint Industry Board of the Electrical Industry, New York	collective bargaining	Employers contribute 5% of payroll to fund, a portion of which supports center
New York Hotel Trades Council and Hotel Association of New York City	collective bargaining	Employers contribute 5.5% of payroll to welfare program, a portion of which supports center
New York Shipping Association—International Longshoremen's Association (Ind.), Brooklyn	collective bargaining	Employers contribute 14 cents per hr. to welfare fund, of which 3 cents go toward operation of center
Union Eye Care Center, Chicago	Shares in $50 unit purchased by unions	Patients' fees and service assessment on unions support center
Union Health Service, Inc., Chicago	collective bargaining	Employers contribute to union welfare funds; unions pay plan $3 per mo. per member, $6 for a couple, and $7 for family
United Wire, Metal and Machine Medical Center, New York	collective bargaining	Employers contribute percentage of gross payroll to welfare fund, a portion of which operates center; originally supported by union
Warehouse and Distribution Workers Union, Local 688, Labor Health Institute, St. Louis	collective bargaining	Employers contribute 5% of payroll to welfare program, a portion of which supports center
Willys Unit, Local 12, UAW, Toledo	collective bargaining	Union contributions, members' fees—employer contributes 4 cents per hr. per employee; $25 affiliation fee paid by local unions; unions contribute 3 cents per member per mo.; patients pay reduced fees for certain services

MEDICAL NEWS

CALIFORNIA

Dr. Rigler Awarded Medal.—At the recent annual meeting of the American Roentgen Ray Society in Washington, D. C., Dr. Leo G. Rigler of Los Angeles was awarded the Caldwell medal. Dr. Rigler, visiting professor of radiology at University of California at Los Angeles School of Medicine and currently president of the Radiological Society of North America, presented the annual Caldwell lecture, which was established in honor of the late Dr. *Eugene W. Caldwell, New York City, past-president* of the American Roentgen Ray Society.

University News.—Dr. Edwin O. Field, Division of Radiobiology, Radiotherapy *Department*, Royal Marsden Hospital, London, has been appointed visiting instructor in medicine at Stanford University School of Medicine, San Francisco, for the academic year 1958-1959. Dr. Field will collaborate on hemotology research being conducted in the isotope laboratory by the departments of medicine and radiology.

COLORADO

University News.—Two research grants to members of the University of Colorado School of Medicine faculty for studies in muscular dystrophy and heart surgery have been announced. The Muscular Dystrophy Association of America, Inc., of New York City, has renewed for another year a grant of $21,500 for research by Cosmo G. Mackenzie, Sc.D., head, department of biochemistry. The project is titled "Identity and Treatment of the Primary Biochemical Lesions in the Muscular Dystrophies." A grant of $15,565 has been made to Dr. Ben Eiseman, professor of surgery, for a study of "Cardiac Valve Substitutes," by the National Heart Institute, Bethesda, Md.——A grant of $24,626, "to enhance the teaching program" of the department of physical medicine and rehabilitation, University of Colorado School of Medicine, Denver, has been received from the Office of Vocational Rehabilitation, U. S. Department of Health, Education and Welfare.

DISTRICT OF COLUMBIA

Society News.—The Washington, D. C. Dermatological Society has elected the following officers for 1958-1959: chairman, Dr. Raymond A. Osbourn, vice-chairman, Dr. Peter N. Horvath, and secretary-treasurer, Dr. June C. Shafer, (Arlington, Va.). Meetings will be held in Washington, D. C., on the fourth Thursday of every month, September through May.

Personal.—Dr. Mathew Ross, formerly of Beverly Hills, Calif., has taken office as medical director of the American Psychiatric Association in Washington, D. C., succeeding Dr. Daniel Blain, who resigned Sept. 1.——Dr. Benjamin Karpman, chief psychotherapist and consultant at Saint Elizabeths Hospital, was invited by the British Institute for the Study and Treatment of Delinquency to lecture in England on general psychiatric problems, Aug. 18-22. Dr. Karpman later spoke before the Spanish Psychological Society.

ILLINOIS

General Practitioners Meet in Chicago.—The 11th annual meeting of the Illinois Academy of General Practice will be at the Morrison Hotel, Chicago, November 3-6. There will be seven sessions of the scientific assembly, including, among other presentations, a panel of experts to answer questions on the business side of medicine; an academy film, "Building for Tomorrow"; the annual dinner dance Wednesday evening; and exhibits. The president and president-elect are, respectively, Drs. Abraham I. Doktorsky and Robert E. Heerens.

Society News.—The following officers of the Illinois Psychiatric Society have been elected for 1958-1959: president, Dr. Nathaniel S. Apter, Chicago; president-elect, Dr. Frances Hannett, Chicago; secretary-treasurer, Dr. Paul E. Nielson, Chicago; and councilors, Drs. Kalman Gyarfas, Chicago, and Lester H. Rudy, Galesburg.——The Illinois Society of Anesthesiologists has elected the following officers: president, Dr. Huberta M. Livingstone, Chicago; vice-president, Dr. Lawrence D. Ruttle, Joliet; secretary, Dr. Clifford A. Baldwin Jr., Wilmette; and treasurer, Dr. Robert F. Finegan, Elgin.

MASSACHUSETTS

Dr. Martha Eliot Awarded Medal.—At the 86th annual meeting of the American Public Health Association, October 28, in St. Louis, the Sedgwick Memorial Medal was presented to Dr. Martha May Eliot, head, department of maternal and child health, Harvard University School of Public Health, Boston, for "distinguished service in public health." Dr. Eliot formerly chief, U. S. Children's Bureau,

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Washington, D. C., in 1947 was the first woman to be elected president of the American Public Health Association. She is a distant relative of the late Charles W. Eliot, president of Harvard University.

University News.—Boston University has received $50,000 from the American Cancer Society, Massachusetts Division. It will be added to funds now being raised for the construction of a 3-million-dollar medical research building. The university has received $900,000 in a $1,500,000 drive to match a federal grant of a similar amount for this project.

MICHIGAN

Appoint Professor of Public Health.—The newly organized research and training service of the University of Michigan School of Public Health, Ann Arbor, will be under the direction of Dr. Hugh B. Robins, formerly health director of Calhoun County, who was appointed professor of public health practice, effective October 1. The research will be financed by a five-year grant of $167,620 from the W. K. Kellogg Foundation, Battle Creek. Dr. Robins, who has been a non-resident lecturer in the School of Public Health, formerly was health commissioner of Charleston, West Virginia.

Society News.—The new officers for 1958-1959 of the Western Michigan Pediatric Society are: president, Dr. John C. Montgomery, Grand Rapids; president-elect, Dr. Clarence L. Hoogerland, Alma; secretary-treasurer, Dr. Samuel S. Jacob, III, 201 Ann St., East Lansing; and assistant-secretary, Dr. Jerome E. Webber, Grand Rapids.

MISSISSIPPI

Society News.—The Mississippi Society of Anesthesiologists has elected the following officers: president, Dr. Thomas J. Marland, Jackson; vice-president, Dr. William E. Sheffield, Charleston; and secretary-treasurer, Dr. Curtis W. Caine, Jackson.

Personal.—Dr. Durward L. Blakey became director of the Division of Preventable Disease Control of the Mississippi State Board of Health on July 1, succeeding Dr. A. L. Gray, who was elevated to the position of state health officer.

University News.—Construction of 80 student housing units on the University of Mississippi School of Medicine campus has begun. Four buildings of 20 units each on Jackson's Lakeland Drive will furnish 44 two-bedroom and 36 efficiency apartments available to single or married students, interns, and residents. Cost of the project will be amortized from rent revenues.——The Mississippi Heart Association has awarded eight seeding research grants and a cardiovascular fellowship to The University of Mississippi School of Medicine, Jackson, totaling $18,800. The health agency also allocated $17,000 toward establishment of a cardiovascular chair at the new medical school.

MISSOURI

Research Training Grant in Microbiology.—The National Institute for Allergy and Infectious Diseases of the U. S. Public Health Service has made a grant of $225,690 for research training in microbiology and virology to St. Louis University School of Medicine, St. Louis, for a five year period. The new program will offer scientists who have Ph.D. degrees in other sciences an opportunity to broaden their training and experience along lines pursued in the microbiology department at this school of medicine. Opportunity will be offered also to provide research training in infectious diseases to young physicians who plan to make microbiology and related basic sciences their career. The new grant, which will augment research in microbiology for medical students, will be under the direction of Dr. R. Walter Schlesinger, director of the department, and Edwin L. Minard, Ph.D., associate professor of microbiology.

NEW JERSEY

Regional Meeting of College of Physicians.—The 13th regional meeting of the American College of Physicians (New Jersey) will be in the auditorium of the Mutual Benefit Life Insurance Company, 520 Broad St., Newark, N. J., November 12, to which all interested physicians and their wives are invited. The scientific program, limited to diseases of the adrenal gland, will be presented by members of the faculty of Columbia University College of Physicians and Surgeons, New York City. Following the symposium, Dr. Frank B. Berry, assistant secretary of defense (health and medical), Washington, D. C., will speak on the relationships between military and civilian medicine. The speaker at the informal dinner will be Dr. Dwight L. Wilbur, San Francisco, president of the American College of Physicians.

International Symposium on Tuberculosis.—Deborah Sanatorium and Hospital at Browns Mills, will sponsor an international symposium on tuberculosis, November 20-22. The morning and afternoon panel sessions will be held at the Bellevue-Stratford Hotel in Philadelphia. The general subjects of the six panels will be "Chemotherapeutic Prophylactic Measures for Tuberculosis"; "The Hospital and Home, Roles in Tuberculosis Management"; "The Problem of Relapse of Tuberculosis Lesions Under Chemotherapy"; "Duration of Drug Treatment"; "Pathological Problems"; "Tuberculosis Case-Finding"; "Surgical Aspects of Treatment of Tuberculosis"; and "The Future Problem of Tuberculosis, Program for its Control." Nearly 50 authorities in this field will serve on the panels. Among the panel members from foreign countries will be Drs. Georges J. Canetti, Paris, France, Johannes Holm, Geneva, Switzerland; John R. Bignall, London, England; Hugh E. Burke, Montreal, Canada; Frederick R. Edwards, Liverpool, England, John M. Robson, London, England; Philip M. D'Arcy Hart, London, England; Frederick G. Kergin, Toronto, Canada; Carl B. Semb, Oslo, Norway, and Hans J. N. Ustvedt, Oslo, Norway. Registration is open without fee to all interested physicians and surgeons. This symposium, which has been endorsed by the National Tuberculosis Association, the American Trudeau Society, and the American College of Chest Physicians, is the first of a projected series under Deborah sponsorship.

Society News.—Officers of the Radiological Society of New Jersey for 1958-1959 are: Dr. George G. Green, Asbury Park, president, Dr. William L. Palazzo, Teaneck, vice-president, Dr. Andrew P. Dedick Jr., Red Bank, secretary, and Dr. William L. Bonnet, Trenton, treasurer. The meeting dates remain: annual meeting in May in Atlantic City; and the fall meeting, October-November, in Newark.

NEW YORK

Dr. Weiss Receives Lectureship Award.—The Albany Medical College of Union University has given its second annual honorary lectureship award to Dr. Paul A. Weiss of the Rockefeller Institute for Medical Research, New York City. This award is given in recognition of "distinguished service to mankind in the fields of science, medicine and teaching." Last year the award was given to William M. Clark, Ph.D., emeritus professor of physiological chemistry at Johns Hopkins University School of Medicine, Baltimore.

University News.—Dr. Ponduri Venketa Ramanarao, professor of bacteriology, Osmania Medical College, Hyderabad, capital of the state of Andhrapradesh, India, has joined the department of microbiology of the State University of New York Upstate Medical Center in Syracuse as a participant under an International Cooperation Administration training program.

Society News.—At the meeting of the New York Allergy Society, November 17, at the Beekman Tower Hotel, 1st Ave. and 49th St., New York City, 8:30 p. m., there will be a panel discussion on "The Single Repository Injection Treatment of Hay Fever," moderated by Dr. Robert A. Cooke, chief of the Institute of Allergy, Roosevelt Hospital, New York. Members of the panel will be Drs. Mary E. H. Loveless of Cornell University Medical College; John H. Mitchell and William F. Mitchell, both of Ohio State University Medical College; and William B. Sherman, chief of allergy, Presbyterian Hospital, New York.

New York City

Grant to Aid Liberian Institute.—The American Foundation for Tropical Medicine, 345 Madison Avenue, announces that Eli Lilly and Company of Indianapolis has made a grant to support the activities of the Liberian Institute of the foundation during the present year—an award similar to the one made by the same company last year. This support, the foundation says, has assisted in making possible expanded research activities of the institute in Liberia, West Africa.

Hospital News.—The Department of Pathology of The Mount Sinai Hospital, New York, has been awarded $171,000 by the U. S. Public Health Service as a research training grant for experimental pathology for five years. Under the program, training of residents and research fellows (trainees) in experimental pathology will be integrated with that of anatomical and clinical pathology. The grant also permits the appointment of a coordinator for the organization of the training in various techniques of experimental pathology.

Hungarian Association Meeting.—The annual Semmelweis meeting of the American Hungarian Medical Association will be November 14 at 8:30 p. m., at the New York Academy of Medicine, Hosack Hall. Dr. Max Thorek of Chicago, founder of the International College of Surgeons, will speak on "Impending Death Under Anesthesia," and Dr. Paul H. Hoch, New York State commissioner of mental hygiene, on "Some Remarks on Semmelweis from a Psychiatric Point of View." Dr. Alexander Borota is president of the society and Dr. G. Peter Halberg, secretary.

Annual Wyckoff Lecture.—Dr. Rodney Smith, senior surgeon to the Victoria Hospital for Children, London, England, and surgical tutor for the Royal College of Surgeons, will deliver the annual John Wyckoff lecture of the New York University College of Medicine at 4:30 p. m., November 5, in the Alumni Hall, 31st Street and First Avenue, on "Surgery Before and After John Hunter." The Wyckoff lecture is sponsored by the Phi Delta Epsilon Fraternity in honor of the late Dr. John H. Wyckoff, who was dean of the New York University College of Medicine from 1932 to 1937.

Conference on Study of Sex.—The first annual conference of the Society for Scientific Study of Sex will be at the Barbizon-Plaza Hotel on Nov. 8 at 9 a. m. The general subjects for discussion will be "Therapeutic Abortion" and "Frigidity." This new society proposes to organize symposiums, seminars, workshops, and conferences to consider problems in the sexual area and later to publish a scientific journal devoted to relevant original studies and reports. The list of charter members contain names of medical scientists who are widely known for their research work. The chairman of the program committee is Dr. Hans M. Lehfeldt, 784 Park Ave., New York 21.

NORTH CAROLINA

New Chairman of Department of Microbiology.—Duke University School of Medicine, Durham, announces that Norman H. Conant, Ph.D., professor of mycology at Duke, has been appointed chairman of the department of microbiology to succeed Dr. David T. Smith, who has been head of the microbiology department since the school of medicine opened in 1930. Dr. Smith resigned as chairman in order to devote more time to teaching and research. He will retain his full professorship and continue as an active teacher. Dr. Conant joined the Duke medical faculty in 1935. He has held consulting and advisory posts that include tropical medicine consultant to the Secretary of War and member of the advisory panel for the office of naval research.

NORTH DAKOTA

General Practitioners Meeting at University.—Dr. Alan K. Johnson, Williston, N. D., president, North Dakota Chapter, American Academy of General Practice, announces that the annual meeting and postgraduate refresher course of the North Dakota Academy of General Practice will be held at the University of North Dakota School of Medicine, November 21-22. Members of the American Academy of General Practice from North and South Dakota and Minnesota are especially invited to attend, plus prospective members from any of these areas. Dr. Richard L. Varco, of the department of surgery, University of Minnesota, and Dr. Maurice H. Stauffer of the department of gastroenterology of the Mayo Clinic, will be guest speakers for the session. For information write Dr. Richard D. Nierling, ℅ Jamestown Clinic, Jamestown, North Dakota.

OHIO

Phi Delta Epsilon Lectureship.—The annual lecture of Phi Delta Epsilon Fraternity, under the auspices of Beta Epsilon Chapter, will be held at the University of Cincinnati College of Medicine, November 20 at 8:30 p. m. The lecturer will be Dr. Claude S. Beck of Cleveland, who will speak on coronary heart disease.

Personal.—Dr. Relja Nedeljkovic has been appointed the Mannheimer Memorial Fellow at the May Institute for Medical Research of the Cincinnati Jewish Hospital. A native of Yugoslavia, Dr. Nedeljkovic spent five years in Belgium, where he engaged in research. At the May Institute, he is collaborating in studies on arteriosclerosis.

Dr. Page Receives Award.—The American Heart Association, at its annual meeting in San Francisco, October 25, gave its award for cardiovascular research to Dr. Irvine H. Page, director of research of the Cleveland Clinic Foundation. Dr. Page was cited for his contribution on hypertension. He will receive $2,500 and a scroll.

Dr. Levine to Lecture on Diabetes.—The Phi Delta Epsilon Fraternity, Upsilon Chapter, will hold its 1958 national lecture at the Cleveland Medical Library Auditorium, November 19, 8:30 p. m. The speaker will be Dr. Rachmiel Levine, chairman, department of medicine, Michael Reese Hospital, Chicago, and his subject will be "Problems in Etiology of Diabetes Mellitus."

OKLAHOMA

Society News.—The Oklahoma Society of Anesthesiologists has elected the following officers: president, Dr. Carl H. Guild, Jr., Tulsa; president-elect, Dr. Harlan K. Sowell, Oklahoma City; and secretary-treasurer, Dr. Lawrence Stream, Oklahoma City.

Personal.—Dr. Bert T. Brundage, of Thomas, has been appointed by Governor Raymond Gary a member of the state board of health to succeed Dr. Roy L. Fisher, of Frederick, who has resigned.——Dr. Gilbert S. Campbell, former assistant professor of surgery, University of Minnesota Medical School, has been appointed professor of surgery at the University of Oklahoma Medical School and chief of surgical service at the Oklahoma City Veterans Administration Hospital, Oklahoma City. As surgery chief at the hospital, he succeeds Dr. Fred A. Quenzer, who transferred to the McKinney, Texas, VA hospital last May.

PENNSYLVANIA

Nutrition Education Programs.—The commission on nutrition of the Medical Society of the State of Pennsylvania, under the chairmanship of Dr. Michael G. Wohl, Philadelphia, in cooperation with the National Vitamin Foundation, will present at the monthly meeting of various county medical societies, discussions on the basic and practical aspects of nutrition as they relate to disease. Several of these discussions have already been held and the remaining ones will be held as follows: Before the Delaware County Medical Society in Media, November 13, Willard Krehl, Ph.D., New Haven, Conn., will discuss "General Therapeutic Nutrition with Emphasis on Arthritic Disease"; before the Northampton County Medical Society at Easton, November 18, Robert W. Hillman's (Brooklyn) subject will be "Treatment of Obesity with Particular Reference to Nutrition"; before the Lancaster County Medical Society, Lancaster, December 3, Dr. Richard W. Vilter, Cincinnati, will speak on "Nutritional and Metabolic Aspects of Cardiovascular Disease"; the two objectives of this program being to stimulate interest in clinical nutrition at state and county levels and to disseminate factual information on nutrition to practicing physicians and the laity; and before the New Jersey Academy of General Practice in Atlantic City, January 10, 1959, Dr. Norman H. Jolliffe, New York City, will discuss "Fats, Cholesterol and Atherosclerosis—a Progressive Report."

Society News.—At a meeting of the Pittsburgh Roentgen Society the following officers were elected for 1958-1959: president, Dr. Harrison H. Richardson, Rochester; vice-president, Dr. Eugene R. Kutz, Pittsburgh; secretary, Dr. Erwin Beck, 3500 Fifth Avenue, Pittsburgh 13; and treasurer, Dr. Julius W. Ambrose, Pittsburgh.

RHODE ISLAND

The Danforth Oration.—Dr. Paul C. Colonna, until recently professor of orthopedic surgery, University of Pennsylvania School of Medicine, Philadelphia, will serve as orthopedic surgeon-in-chief pro tempore at the Rhode Island Hospital, Nov. 6-8. On Nov. 6 he will deliver the Murray S. Danforth Oration on "The Ununited Hip."

SOUTH CAROLINA

Society News.—The South Carolina Chapter of the American Academy of General Practice has installed the following officers: president, Dr. Homer M. Eargle, Orangeburg; president-elect, Dr. I. Ripon Wilson, Charleston; vice-president, Dr. William T. Hendrix, Spartanburg; and secretary-treasurer, Dr. Horace M. Whitworth, Greenville.

Personal.—Dr. Kenneth M. Lynch Jr., dean of the faculty of the Medical College of South Carolina, Charleston, has been honored by award of the "Medallion and Citation" of the American Cancer Society for "outstanding service in the cause of cancer control." The award was made at the South Carolina Division's annual meeting April 1.——Dr. Hugh S. Brown, for the past nine years has maintained a private practice in Spokane, Wash., as a specialist in internal medicine and cardio-vascular diseases, has been appointed medical director of Liberty Life Insurance Company, succeeding Dr. W. S. Fewell, who has retired.

TEXAS

Hospital News.—A grant of $52,000 for a study of how electronic data processing equipment may best be adapted for hospital use has been made by The John A. Hartford Foundation to the Hospital Research and Educational Trust. Dr. Edwin L. Crosby, chairman, board of trustees of the trust, said the study would require about four months and would be carried out in Dallas, at the Baylor University Hospital. The study will include the areas of patients' billings, perpetual inventories, medical records and statistics, payroll and insurance. The Hospital Research and Educational Trust, a nonprofit organization, with grants from foundations and other sources, conducts projects for general improvement of knowledge and practice in the hospital field.

Personal.—Dr. Cyril J. Ruilmann, director of mental health and hospitals, Board for Texas State Hospitals and Special Schools, has been elected chairman of the Southern Regional Council on Mental Health Training and Research, for 1958-59.——Dr. Kenneth M. Earle, associate professor of pathology, University of Texas Medical Branch, Galveston, has been made assistant dean (undergraduate) and Dr. Stephen R. Lewis, assistant professor of surgery at the University of Texas Medical Branch, has been made assistant dean (graduate and postgraduate).——Dr. Herschel F. Connally has been appointed assistant executive director of the Medical Branch of the University of Texas, Galveston. Dr. Connally has been a member of the Commission on Higher Education for the State of Texas.

VERMONT

State Medical Election.—At the annual meeting of the Vermont State Medical Society in Bretton Woods, New Hampshire, in September, Dr. Wayne Griffith of Chester was installed as president and the officers elected were : Dr. Frederick W. Van Buskirk, Burlington, president-elect; Dr. Benjamin F. Clark, St. Johnsbury, vice-president; Dr. Oliver H. Durand, Bennington, secretary; Dr. Gordon B. Smith, Rutland, treasurer; and Dr. William J. Powers, Rutland, speaker of the house.

The following were awarded memberships in the 50-year club: Drs. Benjamin D. Adams, Burlington; Oliver N. Eastman, Burlington; Arthur T. Gillette, Dorset; Archie L. Leonard, Lyndonville; William McFarland, Barre; and John H. Woodruff, Barre.

The annual meeting next year will again be a joint meeting with the New Hampshire Medical Society at the Equinox House in Manchester, Vermont, October 1-4.

WASHINGTON

State Medical Election.—At the annual meeting of the house of delegates of the Washington State Medical Association in Spokane, September 17, the following officers were elected: Dr. Emmett L. Calhoun, Aberdeen, president; Dr. Frederick A. Tucker, Seattle, president-elect; Dr. Milo T. Harris, Spokane, immediate past-president; Dr. Edward C. Guyer, Seattle, vice-president; Dr. Wilbur E. Watson, Seattle, secretary-treasurer; and Dr. Homer W. Humiston, Tacoma, speaker, house of delegates.

GENERAL

22,880 Traffic Deaths in Eight Months.—A forecast by the National Safety Council, Chicago, September 30, was to the effect that a saving of 2,000 lives on the nation's highways in 1958 is a realistic goal. The council based its forecast on the fact that the traffic death toll of 22,880 for the first eight months of this year is 6% below the same period last year.

For the eight months, 32 states had better records than for the same period the year before and 186 cities still had perfect records, the three largest being Orlando, Florida, Evanston, Illinois and Bethlehem, Pennsylvania.

Society News.—The American Academy of Physical Medicine and Rehabilitation has elected the following officers for 1958-59; Dr. Louis B. Newman, Chicago, president; Dr. Clarence W. Dail, San Gabriel, Calif., president-elect; Dr. Ray G. Piaskoski, Wood, Wis., vice-president; Dr. Harriet E. Gillette, Atlanta, Ga., secretary; Dr. James W. Rae Jr., Ann Arbor, Mich., treasurer; and Dorothea C. Augustin, Chicago, executive secretary.

Regional Meeting of College of Physicians.—The regional meeting of the American College of Physicians (New England states, Quebec, and Atlantic Provinces) will be at the Chateau Frontenac Hotel, Quebec, Canada, November 7-8, to which a cordial invitation is extended to all physicians of these regions. There will be no registration fee. In addition to the scientific session, at the banquet Friday evening, Dr. Dwight L. Wilbur, San Francisco, president, American College of Physicians; Monseigneur A. M. Parent, rector of Laval University; and Edward R. Loveland, Philadelphia, executive secretary of the college, will be the guests of honor. The ladies' program includes a luncheon, tour of old Quebec and Laval University, and a visit to the shrine of Saint Anne de Beaupre.

Surgeons' Election.—Dr. Henry W. Meyerding, of Rochester, Minn., was inducted as president of the International College of Surgeons at ceremonies in the Palmer House, Sept. 19, succeeding Dr. Carlos Gama of Sao Paulo, Brazil. Other officers installed were: Dr. A. Mario Dogliotti of Torino, Italy, president-elect, to take office as president in 1960; Dr. Lyon H. Appleby, Vancouver, B. C., first vice-president; Dr. Max Thorek, Chicago, secretary-general; Dr. Ross T. McIntire, Chicago, executive director; Dr. Clement L. Martin, Chicago, treasurer. Dr. Edward L. Compere, Chicago, was installed as president of the United States Section, succeeding Dr. Curtice Rosser, Dallas. Dr. Harry E. Bacon, Philadelphia, was inducted as president-elect, and Dr. A. Neal Owens, New Orleans, as first vice-president.

Meeting of Tropical Medicine Society.—The seventh annual meeting of the American Society of Tropical Medicine and Hygiene will be Nov. 5-8 at the University of Miami School of Medicine, Coral Gables. In addition to scientific papers by local and South American scientists, the 23rd annual Charles F. Craig lecture will be given by Dr. Jerome T. Syverton, University of Minnesota Medical School, Minneapolis. At the dinner Friday evening, the presidential address will be delivered by Donald L. Augustine, Sc.D., Waban, Mass., of the Harvard School of Public Health, on "The Worm Turned—Action and Reaction." The Walter Reed Medal will be presented by Willard H. Wright, Ph.D., Washington, D. C., chairman of the award committee. The next annual meeting will be in Indianapolis October 28-31, 1959.

Conference on Lead Hygiene in Chicago.—The Lead Industries Association, New York City, will present a Lead Hygiene Conference at the Drake Hotel, Chicago, Nov. 6-7. Chairmen of the three sessions will be Dr. Lemuel C. McGee, Dr. George M. Wheatley and Mr. Manfred Bowditch, director of health and safety of the association. Speakers and subjects will include the following:

Effect of Environmental Temperature on Lead Poisoning, Anna M. Baetjer, Sc.D., Baltimore.
Health Control in Storage Battery Manufacture, Dr. Elston L. Belknap, Milwaukee.
Studies of the Lead Content of Waters from Red Lead Painted Standpipes, Dr. Higdon B. Elkins, Iowa City, Iowa.
Common Errors in the Diagnosis of Plumbism, Dr. Rutherford T. Johnstone, Los Angeles.

Attendance is limited to 150 persons. Registration fee for members is $10. For information write the Lead Industries Association, 60 E. 42nd St., New York 17, New York.

Recipients of Pediatric Fellowships.—The recipients of the annual Wyeth Laboratories pediatric residency fellowships have been announced by Dr. Philip S. Barba, past-president of the American Academy of Pediatrics and chairman of the fellowship selection committee. The physician-recipients, from 13 different states, are the first group to benefit from this fellowship program established recently. Each will receive a grant of $4,800 providing for a two-year postgraduate course in pediatrics. The cost of the first three years of the project will be $195,000. Those receiving the fellowship awards included:

Drs. Sidney W. Klein, Baltimore, Md.; Robert B. Cole, Cleveland, Ohio; Floy C. Helwig, Baltimore; Warren D. Grover, Camp LeJeune, N. C.; Luther B. Travis, Fort Benning, Ga.; John D. Siegfried, Red Lake, Minn.; George T. Kimbrough, Birmingham, Ala.; Donald E. Carey, New Orleans, La.; Marvin L. Rallison, Minneapolis; Allan L. Drash, Baltimore; William G. Kenney, Rochester, N. Y., Paula Neyman, New York City; Keith Hammond, Paoli, Ind.; Robert O. Hickman, Salt Lake City; John C. Gilhland, Jackson, Miss.; Jon L. Karlsson, Santa Rosa, Calif., John I. Larkin, Albany, N. Y.; William A. Moon Jr., Denver; George A. Lentz, Baltimore; and Paul J. Uhlig, Oceanside, Calif.

Essay Contest on Maxillofacial Surgery.—The American Society of Maxillofacial Surgeons has announced an essay contest for papers based on some original research (either clinical or experimental) in maxillofacial surgery. Any medical or other university graduate may enter. The essays shall be based on work not previously published, even in part, and shall be submitted in triplicate, in English only, and not more than 4,000 words in length. Manuscripts will not be accepted by the Award Committee after April 1, 1959, and should be sent by registered mail. Certificates will be given to the authors of the first and second prize essays. The winners of these certificates will receive $300 and $200, respectively for travelling expenses. The two winning papers are to be read by the authors before the annual convention of the society, May 10-14, 1959, at the Palmer House, Chicago. The submitted essay becomes the property of the American Society of Maxillofacial Surgeons and shall not be published, without the written permission of the Secretary of the Society, in any journal other than the official journal of the Society, *The American Journal of Surgery*. Information may be obtained from the Secretary of the Society, Dr. Orion H. Stuteville, 700 N. Michigan Ave., Chicago 11.

New Journals of Pharmacology.—Three new journals of pharmacology have been announced. *Biochemical Pharmacology*, an international journal devoted to research into the development of biologically active substances and their mode of action in the biochemical and subcellular level, is edited by a board of which Dr. Alexander Haddow, of the Chester Beatty Research Institute, is chairman. The regional editor for the United States is Dr. Arnold D. Welch, of Yale University, New Haven, Conn. The first volume appeared in July. The Academic Press, Inc., of New York City, has announced the publication of *Toxicology and Applied Pharmacology* with Harry W. Hays, Ph.D., of the National Research Council, as managing editor, assisted by Frederick Coulston, Ph.D., of the Sterling-Winthrop Institute, and Dr. Arnold J. Lehman, of the Food and Drug Administration. The first number is to appear in January, 1959. Interscience Publishers, of New York City, have announced an international bimonthly periodical, *Journal of Medicinal and Pharmaceutical Chemistry*, the first issue to appear toward the end of the year. This will have as editors Mr. Arnold H. Beckett, of the Chelsea College of Science and Technology, London, and Alfred Burger, Ph.D., of the University of Virginia, Charlottesville.

Awards for Research in Radiology.—On behalf of the James Picker Foundation, The National Academy of Sciences–National Research Council announces the continued availability of funds in support of radiological research. The program is oriented toward, but not necessarily limited to, the diagnostic aspects of radiology. Support is not restricted to citizens of the United States or to laboratories within this country. Three types of support are offered: (1) grants-in-aid, designed to encourage investigations offering promise of improvement in radiological methods of diagnosis or treatment of disease, awarded to institutions, rather than to individuals; (2) grants for scholars, designed to bridge the gap between the completion of fellowship training and the period when the young scientist has demonstrated his competence as an independent investigator, applied for by the institution on behalf of the prospective scholar; (3) fellowships in radiological research open to candidates seeking to gain research skills leading to investigative careers in the field of radiology. Candidates must hold the M.D., Ph.D., or Sc.D. degree or the equivalent. Preference will be given to applicants who are 35 years of age or less. Applications for the fiscal year 1959-1960 should be submitted bv Dec. 1. Information and application blanks may be obtained from the Division of Medical Sciences, Room 411, National Academy of Sciences–National Research Council, 2101 Constitution Ave., N. W., Washington 25, D. C. Applications for support of studies to be carried out in Canada should be directed to the Awards Office, National Research Council of Canada, Ottawa 2, Canada.

Outbreaks of Infectious Encephalitis.—According to the Morbidity and Mortality Weekly Report of the United States Public Health Service, dated September 26, 1958, a total of 116 cases of infectious encephalitis was reported for the current week; 30 in Kansas, 17 in California, 10 in Georgia, 9 in Nebraska, 7 in Ohio, and 6 in Texas. The report for Kansas showed that 1 of the 30 had been confirmed as western equine and 1 as St. Louis encephalitis, 2 as mumps encephalitis, and 26 as unknown etiology. Four cases reported as "meningococcal encephalitis" were placed in the category of meningococcal infections.

The California Department of Public Health reports that 3 new cases of arthropod-borne encephalitis were confirmed during the 2-week period ended September 18. In the 2 preceding 2-week periods 12 and 10 cases had been confirmed. The 3 new cases were diagnosed as western equine encephalitis infections, making a total of 31 confirmed cases of this disease. Three cases of St. Louis encephalitis have been confirmed this year. One of the 3 cases of western equine encephalitis was presumably contracted in Santa Clara County, which is outside of the usual endemic area for arthropod-borne encephalitis, but the individual was reported to have been in Utah during the summer although the exact dates of his stay were not known.

The Colorado Communicable Disease Summary for the week ended September 6 contains a report that 4 cases of arthropod-borne encephalitis have been confirmed as the western equine type. Four other cases have been ruled out by laboratory tests as cases of arthropod-borne encephalitis.

Competition for Treatise on Rheumatic Diseases.—The 4th International Award AQUI TERME (Hot Springs) of Rheumatology, under the auspices of the Italian Society of Rheumatology, has been announced. The international competition is for a prize for an unpublished treatise on the rheumatic disease (award 1,000,000 lire [$1,600]) and for a publication in the form of a composition or monograph on the subject of rheumatology (award 500,000 lire).

Rules are as follows:

Treatises seeking the prize of lire 1,000,000 must discuss problems involving the articular physiopathology, the clinical aspects or treatment of the arthritic or rheumatic diseases.

Publications seeking the prize of lire 500,000 must discuss rheumatologic arguments in a form of a composition or monograph.

This competition is open to all Italian and foreign physicians.

The prize of Lire 1,000,000 might be awarded to one publication or divided between two publications. The prize of lire 500,000 is indivisible.

The committee of award will consist of six authorities on rheumatic and arthritic diseases.

The jury will have the right to cancel this competition if in its judgment the quality of the publications will not be up to standards.

Publications may be written in Italian, French, English, German, or Spanish. It is desirable to make an abstract of the publication in either Italian or French.

Publications must be counter-signed with a motto; the same motto must be repeated on the sealed envelope on which the following indications must be written: motto, the name and address of the author or authors.

Publications must be typewritten (for award of lire 1,000,000); typewritten or printed (for award of lire 500,000) and send in 8 copies, postage prepaid and insured to: Azienda Autonoma di Cura di Acqui Terme (Piemonte, Italy).

The closing date of the competition is December 31, 1958.

EXAMINATIONS AND LICENSURE

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates, Inc.: Medical schools in the United States and Foreign Countries, Feb. 17 and Sept. 22. Executive Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alaska:[*] On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

California: *Oral Examination.* San Francisco, November 15. *Oral and Clinical Examination for Foreign Medical School Graduates.* San Francisco, June 15; Los Angeles, August 17; San Francisco, November 16. Sec., Dr. Louis E. Jones, 1020 N Street, Sacramento.

Colorado: *Endorsement.* Denver, Oct. 14. *Written.* Denver, Dec. 9-10. Exec. Sec., Mrs. Beulah H. Hudgens, 715 Republic Bldg., Denver 2.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Maine: *Examination and Reciprocity.* Portland, Nov. 12-14. Sec., Dr. Adam P. Leighton, 142 High St., Portland.

New Mexico:[*] *Examination and Reciprocity.* Santa Fe, Nov. 17-18. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

Ohio: *Examination.* Columbus, Dec. 16-18. *Endorsement.* Columbus, Dec. 16-18. Sec., Dr. H. M. Platter, Wyandotte Bldg., Columbus 15.

South Carolina: *Endorsement.* Columbia, Dec. 9. Sec., Dr. H. E. Jervey, Jr., Blanding Bldg., Columbia.

Texas:[*] *Examination and Reciprocity.* Fort Worth, Dec. 4-6. Sec., Dr. M. H. Crabb, 1714 Medical Arts Building, Fort Worth 2.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: *Examination.* Juneau, Nov. 4. Sec., Dr. R. Harrison Leer, Room 204, Alaska Office Bldg., Juneau.

District of Columbia: *Reciprocity. Examination.* Washington, Nov. 13-14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N. W., Washington 6.

Kansas: *Examination and Reciprocity.* Kansas City, Nov. 24-25. Sec., Dr. L. C. Heckert, Pittsburg.

Oklahoma: *Examination.* Oklahoma City, Mar. 27-28. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Texas: Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Milwaukee, Dec. 6, Madison, Apr. 4. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

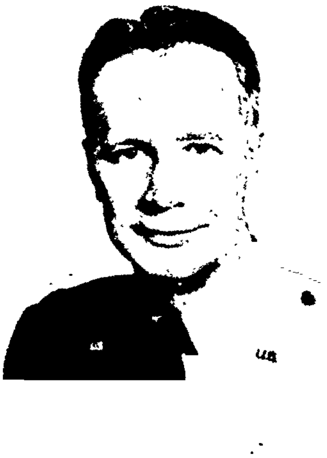
[*] Basic Science Certificate required.

GOVERNMENT SERVICES

AIR FORCE



Colonel Benford Named Director of Medical Publication Agency.—Col. Robert J. Benford, M. C., has been named director of the Armed Forces Medical Publication Agency and editor of the *U. S. Armed Forces Medical Journal.* He succeeds Capt. Bennett F. Avery, M. C., U. S. N., who has been appointed national coordinator of the Medical Education for National Defense program.

Colonel Benford, who recently completed a tour of duty in the Office of the Assistant Secretary of Defense (Health and Medical), served as staff surgeon of the XX Bomber Command in World War II. He is a member of the editorial advisory board of *Aero/Space Engineering*, a monthly journal of the Institute of Aeronautical Sciences, and the author of "Doctors in the Sky," a history of aviation medicine.

General Harry Armstrong Retires.—Major Gen. Harry G. Armstrong, formerly surgeon general of the U. S. Air Force, retired Sept. 1, after almost 30 years of military service. While commandant of the School of Aviation Medicine, he established, on Feb. 9, 1949, the first Department of Space Medicine. In 1935 he was the first physician to attempt a delayed opening parachute jump, of which a report was published in The Journal, Oct. 5, 1935. He was the first to recognize explosive decompression as one of the most hazardous problems in the use of pressurized cabins and, in many of those experiments, he himself was the test subject.

General Armstrong received a Master of Arts degree in internal medicine from the University of Cincinnati and a Master of Science degree in physiology from the University of Toronto. He was elected president of both the Aero Medical Association and the Association of Military Surgeons in 1951. For the past three years he has been surgeon of the U. S. Air Forces in Europe.

ARMY

Personal.—On Oct. 1, Col. Howard W. Doan, M. C., became surgeon of the First Army, with headquarters at Governors Island, New York, succeeding Brig. Gen. Roger G. Prentiss who retired on Sept. 30. Colonel Doan's previous assignment was deputy commander of the Fitzsimons Army Hospital in Denver.

General Prentiss Retires.—Brig. Gen. Roger G. Prentiss, surgeon of the First Army with headquarters at Governors Island, New York, retired Sept. 30, after more than 30 years' service as a medical officer. When World War II broke out, General Prentiss was called to the surgeon general's office in Washington, D. C., to become director of medical research and development. Later he went to Europe with a special intelligence team whose mission was to enter captured German towns to collect data on technical advances by the Germans. In 1950 he became chief of the Historical Division in the surgeon general's office and in 1951 executive officer of the surgeon general's office. At a parade in his honor on Sept. 24, First U. S. Army Commander, Lieut. Gen. B. M. Bryan, presented to General Prentiss the second award of the Legion of Merit. General and Mrs. Prentiss plan to make their home in Florida.

Establish Medical Research and Development Command.—The surgeon general's office has announced the activation of the Army Medical Service's new Research and Development Command. Brig. Gen. Joseph H. McNinch has been appointed Commanding General of the new command and will assume his duties about Nov. 1. General McNinch is returning to Washington from his post as surgeon, Armed Forces Far East, U. S. Eighth Army, Japan.

Research studies with which the new command will be concerned include the medical effects of ionizing radiation; the prevention and treatment of communicable diseases in overseas areas; surgical problems in the care of the burned and wounded; medical problems of operations under temperature extremes and other adverse environmental conditions; and the physiological and neuropsychiatric problems of military operations.

NAVY

Medical Corps Retirements.—Capt. William W. Ayres, M.C., was placed on the retired list on Sept. 1, 1958, after completing more than 20 years' active service. Having been specially commended by the head of the executive department for his performance of duty in actual combat, he will be advanced on the retired list to the rank of rear admiral.

Capt. Victor G. Colvin, M.C., was placed on the retired list on Sept. 1, after completing more than 27 years' active service.

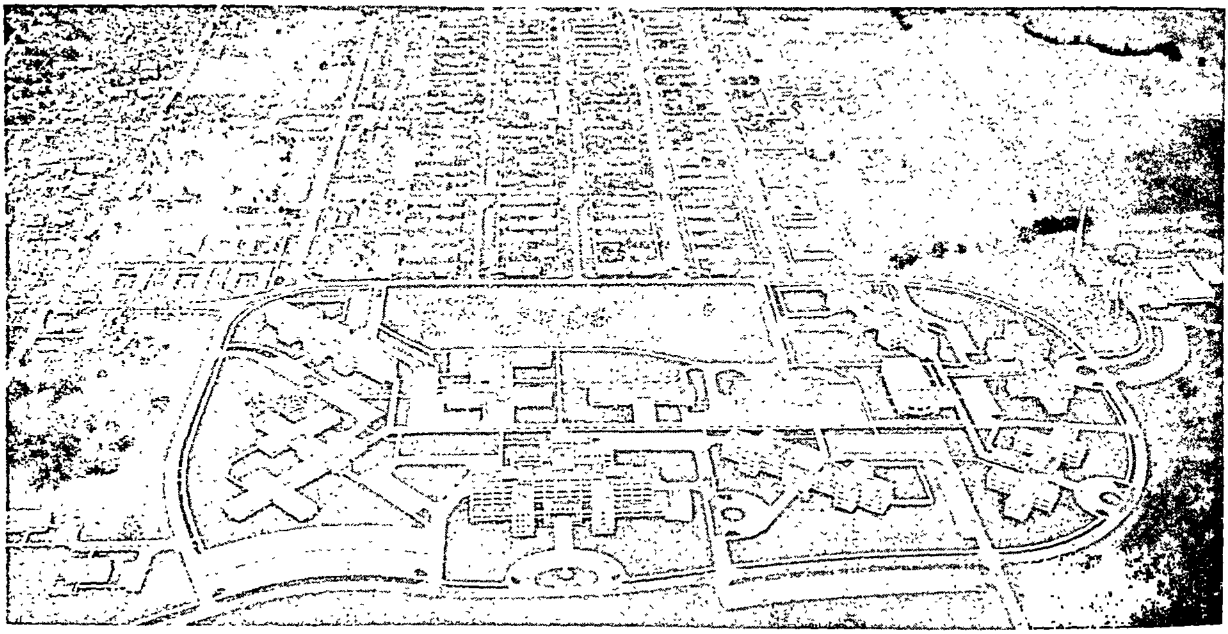
Capt. Thomas M. Foley Jr., M. C., was placed on the retired list on Sept. 1, after completing more than 20 years' active service.

VETERANS ADMINISTRATION

Proposed Neuropsychiatric Hospital at Brecksville, Ohio.—The VA announced Sept. 19 that bids will be accepted up until Nov. 4 for the construction of an estimated $20,500,000 veterans' hospital at Brecksville, Ohio. Aside from the buildings to be constructed, the project includes roads, walks, drainage, landscaping, grading, and wrecking and removal of certain existing structures. In general, the buildings will have concrete and steel frames, reinforced concrete foundations and floors, and exterior brick and masonry walls with stone trim and built-up roofs. Specifications are available from the Director, Design Service, Veterans Administration, Munitions Building, Washington 25, D. C.

The Sixtieth Hospital Since World War II.—The Veterans Administration dedicated a new 1,011-bed hospital for neuropsychiatric patients on Aug. 24, at Topeka, Kan. This, the 60th VA hospital built since World War II, replaces the temporary structures built for the Army in 1943 and later turned over to the Veterans Administration. The new hospital is on Gage Boulevard, three miles from the center of Topeka, on a site of about 150 acres. The hospital proper comprises about 20 buildings of reinforced concrete, with brick facing. The cost of construction approximated 20 million dollars. It will be staffed by about 1,150 employees. Among the speakers at the dedication were Dr. Karl A. Menninger of Topeka and Dr. William S. Middleton, VA chief medical director. The U. S. Army Band from Fort Riley, Kansas, provided music, and Mr. David Neiswanger, chairman, Executive Committee, Menninger Foundation, was master of ceremonies.

Personal.—Dr. Edward F. Zimmerman, director, professional services, VA hospital, Coral Gables, Fla., has been appointed manager of the West Side VA Hospital in Chicago, succeeding Dr. Lee H. Schlesinger, who was appointed VA area medical director at Columbus, Ohio. The West Side hospital is a 495-bed facility for general medical and surgical patients. Dr. Louis B. Newman, chief, physical medicine and rehabilitation service, VA Research Hospital, Chicago, has been presented the agency's Meritorious Service award. Dr. Newman was cited for outstanding service in organizing the research hospital's physical medicine and rehabilitation service and the VA center for rehabilitation of blinded veterans at the Hines, Ill., VA Hospital. Dr. Newman is president of the American Academy of Physical Medicine and Rehabilitation. Dr. A. W. Kruger, formerly manager of the Brooklyn, N. Y., VA Hospital, has resigned from the Veterans Administration to accept the post of consultant on health services to the National Committee on Aging of the National Social Welfare Assembly, 345 E. 46th St., New York City.



Veterans Administration Hospital, Topeka, Kan.

PUBLIC HEALTH SERVICE

Research Grants Awarded in July and August.—Research grants and fellowships totaling $42,665,767 were awarded during the months of July and

August by the National Institutes of Health, Bethesda, Md. In all, 2,793 grants were made to 489 institutions in 48 states, the District of Columbia, 2 territories, and 12 foreign countries. More than half of the money went for the support of research projects concerned with allergy, infectious diseases, heart disorders, and various basic problems in the medical and biological sciences. About one-third of the total number of grants were for new projects, of which 224 are in the field of biological sciences basic to medicine.

Two and One-half Billion Dollars Spent on Hospital Construction.—In a publication on the nation's health facilities, just issued by the Public Health Service, is a summary of the Hill-Burton program up to Jan. 1, 1958. During the first 10 years of the program, 3,047 projects—general hospitals, nursing homes, diagnostic and treatment centers, rehabilitation facilities, public health centers, and state health laboratories—were approved for construction. Of the total cost of 2.5 billion dollars, the state and local share was nearly 1.7 billion. The number of people in the United States without ready access to general hospitals has dropped from 10,000,000 to 2,800,000 since 1948, the Public Health Service reported.

More Than 9,000 Grants in One Year.—The National Institutes of Health, Bethesda, Md., awarded 9,534 grants for research, training, and construction in nonfederal institutions during the fiscal year ended June 30. Of the total, $136,112,014, more than two-thirds—$99,480,968—went to support 7,028 research projects concerned with major diseases and problems in the medical and biological sciences. The grants were made to 699 institutions in 48 states, the District of Columbia, 2 territories, and 28 foreign countries. Grants to help build, equip, or expand 177 research facilities, totaling $30,200,095, were awarded on a matching basis to 134 institutions throughout the country. Research fellowships totaling $6,430,951 were awarded to 2,329 fellows. Eighty-four United States scientists were awarded fellowships for study abroad, while 16 scientists from other countries received fellowships for study in outstanding institutions in the United States.

Grant Support for Training in Psychiatry.—The National Institute of Mental Health is offering grant support for a training program for general practitioners and other physicians engaged in the practice of medicine other than psychiatry. Funds are available during the current year (fiscal year 1959) and training institutions may submit applications at any time. The program has two purposes:

1. To foster the development of postgraduate training in psychiatry for practitioners who wish to increase their psychiatric knowledge and skills in order to be able to deal more effectively with the emotional aspects of illness generally and to play a more effective role in the treatment and prevention of mental illness. These courses will be designed for the physician who plans to continue practicing in his own field.

Grant support is being offered to medical schools, hospitals, clinics, and medical and psychiatric societies for the development and expansion of such postgraduate training in the form of courses, institutes, and seminars. This support does not include fees, subsistence, or travel for the physicians who attend.

Support of this type of training may be for a particular professional group over a given period, or for training offered regularly as part of the postgraduate curriculum of a medical school, hospital, or clinic, or as part of the educational program of a medical or psychiatric society.

Physicians interested in obtaining this type of training should apply to medical schools, hospitals, clinics, and medical or psychiatric societies which have, or are developing, such training opportunities.

2. To provide support at an adequate level for psychiatric residency training for physicians in practice who wish to become psychiatrists. Training stipends up to a maximum of $12,000 a year are available. The level of payment will be determined by the training institutions who will also make the award to the individual physicians. The National Institute of Mental Health will make awards of grants for this purpose to training institutions and not to individuals.

Physicians interested in support for this type of training should apply to training institutions which are approved for psychiatric residency training.

Inquiries about the program should be sent to Dr. Seymour D. Vestermark, Chief, Training Branch, National Institute of Mental Health, Bethesda 14, Md.

SELECTIVE SERVICE

Physical Examination of Physicians for the Armed Forces.—The director of the Selective Service System, Lewis B. Hershey, issued the following operations bulletin on Sept. 22.

1. It is currently reported that too few physicians are volunteering for active duty and residency programs to meet service requirements.

2. If the present trend continues, the Selective Service System will be called upon to deliver physicians on a special call. Local boards will be expected, in anticipation of a possible special call for physicians (but not dentists), to proceed with the physical examination of all physicians who are in class I-A or class I-A-O and have not been examined or who are in class IV-F under the provisions of section 1622.44 (a) of the regulations.

3. Operations Bulletin no. 181, issued Aug. 19, 1957, on the subject "Postponement of Armed Forces Physical Examination and Induction of Physicians and Dentists," is being amended to discontinue the postponement of the examination and induction of physicians.

4. For the purposes of this bulletin a physician is any registrant who has received the degree of bachelor of medicine or doctor of medicine.

DEATHS

Ahroon, Carl Richard Jr. Ⓜ Bloomington, Ill.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1932; veteran of World War II; associated with St. Joseph's and Mennonite hospitals in Bloomington and Brokaw Hospital in Normal, where he died Aug. 25, aged 53, of coronary artery disease.

Ausban, Henley Brown Ⓜ Doyle, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1912; died July 19, aged 79.

Baldwin, Arthur Kirby Ⓜ Long Beach, Calif.; born in Berwick, Ill., July 12, 1888; Rush Medical College, Chicago, 1916; certified by the National Board of Medical Examiners; enlisted in the Army and served with the American Occupational Forces in Siberia in 1919 and 1920; member of the American Society of Anesthesiologists and the Illinois Society of Anesthesiologists; served four times as president of the Green County (Ill.) Medical Society; the Illinois State Medical Society selected him as "General Practitioner for 1958"; practiced in Carrollton, Ill., where he was associated with Carrollton Hospital; died in the Seaside Memorial Hospital May 12, aged 69, of carcinoma of the liver.

Bennett, Marion Horton Ⓜ Big Spring, Texas; Tulane University School of Medicine, New Orleans, 1921; veteran of World War I; chief of staff, Howard County Hospital Foundation; died Aug. 25, aged 63, of ventricular fibrillation.

Booher, James Mathew, Chicago; Kentucky University Medical Department, Louisville, 1905; died in the Manteno (Ill.) State Hospital May 12, aged 78.

Bowman, James Luther Ⓜ Montgomery, Ala.; University of Virginia Department of Medicine, Charlottesville, 1897; served as secretary-treasurer of the Montgomery County Medical Society; veteran of World War I; formerly county health officer; for many years assistant head of the Montgomery County Health Department; died Aug. 24, aged 84.

Calkins, Irving Romaro Ⓜ Springfield, Mass.; Baltimore Medical College, 1896; died Aug. 26, aged 82, of cerebral hemorrhage and mitral stenosis.

Case, Frank William, Cincinnati; Miami Medical College, Cincinnati, 1907; member of the Ohio State Medical Association; served as resident physician at the Christ Hospital where he died Aug. 25, aged 76.

Chalfant, Estalee Martha, Shinnston, W. Va.; Illinois Medical College, Chicago, 1904; American College of Medicine and Surgery, Chicago, 1905; died in Clarksburg Aug. 19, aged 89.

Dahlstrom, Arthur William, Albuquerque, N. M.; Marquette University School of Medicine, Milwaukee, 1916; member of the American Trudeau Society; joined the U. S. Bureau of Indian Affairs in 1935; served as special physician at large for the Indian Service, and as superintendent of the Indian Sanitarium; died Aug. 26, aged 68, of bilateral subdural hematoma and arteriosclerosis.

Daley, Thomas Robert, Oakland, Calif.; University of Wisconsin Medical School, Madison, 1951; interned at the Highland-Alameda County Hospital, where he served a residency; served a residency at the Samuel Merritt Hospital in Oakland and the Herrick Memorial Hospital in Berkeley; associated with the Veterans Administration Hospital; died Aug. 30, aged 33, in an automobile accident near Winters.

Ekstrom, John E., Chicago; Rush Medical College, Chicago, 1909; for many years on the staff of the Ravenswood Hospital; died in the Burnham City Hospital in Champaign Aug. 24, aged 75.

Gaberman, Peter Ⓜ Los Angeles; born in Odessa, Russia, Feb. 28, 1904; University of Illinois College of Medicine, Chicago, 1928; formerly practiced in Chicago, where he was associate professor of medicine at the Chicago Medical School, and on the staffs of the Cook County and Mount Sinai hospitals; veteran of World War II; member of the Illinois State Medical Society and the American College of Cardiology; specialist certified by the American Board of Internal Medicine; died in Cedars of Lebanon Hospital Sept. 7, aged 54, of acute coronary thrombosis with myocardial infarction.

Gault, Edwin Sartain Ⓜ Philadelphia; born in Philadelphia Dec. 23, 1893; Hahnemann Medical College and Hospital of Philadelphia, 1920; on the faculty of Temple University School of Medicine; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists; fellow of the College of American Pathologists; consultant for the U. S. Public Health Service; joint author of "Essen-

Ⓜ Indicates Member of the American Medical Association.

tials of Pathology"; associated with Episcopal Hospital and the Temple University Hospital, where he died Sept. 1, aged 64.

Goff, William Hunter Ⓜ Rockford, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1935; served as health officer of Coosa County; died July 15, aged 50, of coronary occlusion.

Grant, John Joseph Ⓜ Freeport, Ill.; University and Bellevue Hospital Medical College, New York City, 1911; past-president of the Stephenson County Medical Society; fellow of the International College of Surgeons and the American College of Surgeons; veteran of World War I; served as president of the medical staff at St. Francis Hospital, where he died Aug. 23, aged 72.

Gray, Robert, Philadelphia; Temple University School of Medicine, Philadelphia, 1912; died May 1, aged 79, of pulmonary embolism and rheumatic heart disease.

Greene, George A., Yates Center, Kan. (licensed in Kansas in 1901); died in the Newton Memorial Hospital, Winfield, Aug. 22, aged 85, of diabetes mellitus, bronchopneumonia, and congestive heart failure.

Hardesty, Henry O. Ⓜ Jennings, Kan.; Kansas Medical College, Topeka, 1900; served overseas during World War I; died Aug. 17, aged 88, of coronary artery disease.

Heyroth, Francis Farnham Ⓜ Cincinnati; University of Cincinnati College of Medicine, 1925; associate professor of industrial health and biological chemistry at his alma mater, where he received his Ph.D. in 1929; retired as assistant director of the Kettering Laboratory at his alma mater; formerly vice president of the Cincinnati Board of Health; a member of the National Advisory Dental Research Council of the U. S. Public Health Service; a member of the American Chemical Society which in 1953 presented him with its fourth annual Eminent Chemist Award; died Aug. 18, aged 63, of cerebral hemorrhage and hypertension.

Hill, Ralph Lee, Alexander, Va.; born July 6, 1876; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1900; an associate member of the American Medical Association; past-president of the Pennsylvania Psychiatric Society; specialist certified by the American Board of Psychiatry and Neurology; past-president of the Berks County (Pa.) Medical Society and the Pennsylvania Psychiatric Society; member of the American Psychiatric Association; veteran of World War I; medical superintendent of the Allegheny County Home and Hospital in Woodville, Pa., from 1914 to 1927 and the Wernersville (Pa.) State Hospital from 1927 to 1954; in 1940 received an honorary doctor of science degree from Franklin and Marshall College, Lancaster, Pa.; died in the Jamestown (N. Y.) Hospital Aug. 22, aged 82, of uremia.

Howell, Asa, Uvalde, Texas; University of the South Medical Department, Sewanee, Tenn., 1899; died May 19, aged 85.

Hurd, Annah Ⓜ Minneapolis; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1900; died July 24, aged 86.

Hurd, Laura B., San Francisco; Hahnemann Medical College of the Pacific, San Francisco, 1897; served on the staff of the Hahnemann Hospital, where she died Aug. 31, aged 88, of pulmonary embolism.

Hydrick, John Lee, Phoenix, Ariz.; born Oct. 25, 1888; Jefferson Medical College of Philadelphia, 1915; field representative of the Rockefeller Foundation in New York City from 1916 to 1953 and worked extensively in South American countries; a member of the World Health Organization expert advisory panel on health education of the public, and received decorations from the Netherlands, Peru, and Ecuador governments; on Sept. 1, 1956 was appointed acting city health director and the following year became co-director of the city and county health department; in 1954 received an honorary degree of doctor of law from Wofford College, Spartanburg, S. C.; died Aug. 29, aged 69.

Ingarra, Thomas Salvatore Ⓜ Kingston, N. Y.; New York University College of Medicine, New York City, 1949; fellow of the American Society of Anesthesiologists; in 1955 served in the Army, stationed at Fort Riley, Kan., as chief of the department of anesthesiology until 1957; on the staffs of the Kingston Hospital and the Benedictine Hospital, where he died Aug. 28, aged 40, of lymphosarcomatosis.

Kauffman, Kalman L. Ⓜ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1938; died Aug. 16, aged 46.

Kavaler, Samuel, Brooklyn; Long Island College Hospital, Brooklyn, 1922; member of the Medical Society of the State of New York; died Aug. 1, aged 64, of coronary occlusion.

Kavle, Carleton Porter Ⓜ Niagara Falls, N. Y.; University of Buffalo School of Medicine, 1932; also a graduate in pharmacy; president of the Niagara County Medical Society; associated with Mount St. Mary's Hospital and the Memorial Hospital, where he died Aug. 24, aged 57, of hepatitis.

Key, William Frank Ⓜ Fort Worth, Texas; Baylor University College of Medicine, Dallas, 1919; died Aug. 23, aged 67, of arteriosclerotic heart disease.

Mackey, Robert Bliss, Springville, Pa.; Medico-Chirurgical College of Philadelphia, 1908; veteran of World War I; died Aug. 25, aged 74, of rupture of an aneurysm of the abdominal aorta.

McDonald, John Thomas Ⓢ Monroe, Tenn.; University of Nashville Medical Department, 1900; died in the Lady Ann Hospital in Livingston July 24, aged 90.

McGarry, Thomas Francis, Rutland, Vt.; University of Vermont College of Medicine, Burlington, 1921; associated with the Rutland Hospital; died Aug. 19, aged 61, of myocarditis.

McLean, Hugh Clayton, San Diego, Calif.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1903; served in the Canadian Army during World War I; died Aug. 14, aged 90, of arteriosclerosis.

Marsh, Charles Lafayette Ⓢ Valley, Neb.; University of Nebraska College of Medicine, Omaha, 1941; member of the American Academy of General Practice; for 15 years a member of the Selective Service System; served on the District 33 board of education; on the staff of the Nebraska Methodist Hospital in Omaha; died in Portland, Ore., Aug. 26, aged 45, of fatty degeneration of the liver.

Mentzer, John F. Ⓢ Ephrata, Pa.; Jefferson Medical College of Philadelphia, 1882; on the staff of the Ephrata Community Hospital; for many years trustee of the Harrisburg (Pa.) State Hospital; served as a member of the board of health, school director, postmaster, deputy coroner, and county treasurer; chairman of the board of directors and past-president of the Ephrata Farmers National Bank; died Aug. 28, aged 96, of cerebral thrombosis.

Michaelis, Lucia Ⓢ Shaker Heights, Ohio; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1922; died in the Mount Sinai Hospital Aug. 19, aged 61.

Monk, Louis, New York City; Fordham University School of Medicine, New York City, 1911; an associate member of the American Medical Association; died in the Royal Hospital July 25, aged 81, of coronary thrombosis and arteriosclerosis.

Morris, Benjamin Franklin, Paducah, Ky.; Louisville (Ky.) Medical College, 1898; also a druggist; died in Riverside Hospital, Aug. 16, aged 81, of cerebral hemorrhage.

Morris, Elliston Joseph, St. Davids, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1886; an associate member of the American Medical Association; for many years associated with the Episcopal Hospital in Philadelphia; died in Devon Aug. 31, aged 95.

Muller, Lula Johnson Power, Montclair, N. J.; University of Virginia Department of Medicine, Charlottesville, 1946; interned at the Lenox Hill Hospital in New York City and served a residency at St. Luke's Hospital in New York City; associated with Mountainside Hospital; died near Susanville, Calif, Aug. 28, aged 37, of injuries received in an automobile accident.

Murphy, Leonard J. Ⓢ Chicago; Northwestern University Medical School, Chicago, 1916; veteran of World War I; retired in 1956 as director of the Murphy Clinical and X-Ray Laboratory; died in the Swedish Covenant Hospital Aug. 29, aged 76, of diabetes mellitus and arteriosclerosis.

Nelson, Cedric Henry Ⓢ Billings, Mont.; University of Nebraska College of Medicine, Omaha, 1923; past president of Yellowstone Valley Medical Society; served as past-president and vice president of the state board of medical examiners; past chairman of District 2 School Board; veteran of World War I; since 1951 health officer; a staff member at St. Vincent and Deaconess hospitals; died Aug. 20, aged 61, of complications following surgery for aortic aneurysm three months previously.

Noyes, Harriett Louella Ⓢ Rumford, Maine; College of Physicians and Surgeons, Boston, 1911; died in the Rumford Community Hospital July 18, aged 69, of sarcoma.

Parker, Rupert Merrill Ⓢ Moline, Ill.; Northwestern University Medical School, Chicago, 1896; formerly practiced in Chicago; died in the Lutheran Hospital Aug. 28, aged 88, of injuries received in an automobile accident.

Pennell, Franklin Howard Ⓢ Fostoria, Ohio; Ohio State University College of Medicine, 1920; associated with Fostoria City Hospital; died Aug. 17, aged 63, of coronary occlusion.

Poppen, Joseph A. Ⓢ Burr Oak, Kan.; St. Louis University School of Medicine, 1908; served for many years on school boards in both Ionia and Burr Oak; at one time superintendent of schools at Glen Elder; on the staffs of Beloit (Wis.) Community Hospital and St. Joseph's Hospital, Concordia, where he died Aug. 16, aged 82, of cerebral hemorrhage.

Reed, Wendell Phillips Ⓢ Buffalo; University of Buffalo School of Medicine, 1932; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; consulting urologist Wyoming County Community Hospital, Warsaw, and Our Lady of Victory Hospital, Lackawanna; past-president of the medical staff, Millard Fillmore Hospital, where he died Aug. 20, aged 54.

Reeves, Emory West, Cotulla, Texas; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; veteran of World War I; died June 14, aged 79.

Rohr, Joseph Ⓜ New York City; University and Bellevue Hospital Medical College, New York City, 1908; died July 20, aged 76, of coronary artery disease.

Runge, Otto Ernst, Ridgewood, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1914; died July 30, aged 69, of carcinoma of the rectum with metastasis to the liver and lungs and diabetes mellitus.

Sappington, William Fulford Ⓜ Lieut., Colonel, U. S. Army, retired, Waco, Texas; University of Maryland School of Medicine, Baltimore, 1901; veteran of World Wars I & II; entered the medical corps of the U. S. Army in 1920; service member of the American Medical Association; retired March 31, 1942; died June 3, aged 79.

Schabinger, Charles, Philadelphia; Medico-Chirurgical College of Philadelphia, 1899; also a graduate in pharmacy; an associate member of the American Medical Association; died Aug. 24, aged 86, of pneumonia and arteriosclerosis.

Schwartz, William H., Houston, Texas; Dunham Medical College, Chicago, 1902; Hering Medical College, Chicago, 1904; died in St. Luke's Hospital May 19, aged 81.

Seth, Raymond Ephraim Ⓜ Seattle; University of Minnesota Medical School, Minneapolis, 1929; member of the Industrial Medical Association; veteran of World War II; on the staff of the Swedish Hospital; died Aug. 24, aged 54, of a self-inflicted bullet wound in the head.

Slayton, Frederic Hosea, Wichita, Kan.; Rush Medical College, Chicago, 1901; served on the staff of the Wesley Hospital; died Aug. 14, aged 83, of heart disease.

Southard, Mabel Austin, Los Altos, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1900; died Aug. 5, aged 76, of coronary thrombosis.

Stout, Henry Isaiah Ⓜ Sherman, Texas; George Washington University School of Medicine, Washington, D. C., 1907; on the staff of the Wilson N. Jones Hospital; died Aug. 29, aged 74, of acute myocardial infarction and arteriosclerosis.

Thompson, Joseph Ⓜ Creedmoor, N. C.; Kentucky University Medical Department, Louisville, 1904; died Aug. 22, aged 76.

Tietze, Herman Christian, Edwardsville, Ill.; Bennett Medical College, Chicago, 1913; past-president of the Madison County Medical Society; veteran of World War I; died in the Veterans Administration Hospital, Jefferson Barracks, Mo., Aug. 24, aged 73.

Turner, Andrew Jackson Ⓜ Garnett, Kans.; Kansas City (Mo.) Medical College, 1902; veteran of the Spanish-American War and World War I; died Aug. 4, aged 79, of chronic brain syndrome and cerebral arteriosclerosis.

Underwood, Robert Alfred Ⓜ Delta, Colo.; College of Medical Evangelists, Loma Linda and Los Angeles, 1933; certified by the National Board of Medical Examiners; member of the American Academy of General Practice; at one time city physician in Lincoln, Nebr.; on the staff of the Delta Memorial Hospital; died Aug. 17, aged 55, of coronary thrombosis.

Vaughan, Merritt Carlton Ⓜ Buffalo; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1911; associated with Deaconess, Millard Fillmore, Sisters of Charity, and Lafayette General hospitals; died Aug. 22, aged 68, of bronchopneumonia.

Weinstein, Max Irving Ⓜ Methuen, Mass.; Middlesex College of Medicine and Surgery, Waltham, 1936; served during World War II; associated with Bon Secours Hospital in Methuen, Clover Hill Hospital in Lawrence and the Lawrence (Mass.) General Hospital where he died Aug. 15, aged 47, of coronary thrombosis.

Wood, William Ellege Ⓜ Elgin, Texas; University of Georgia Medical Department, Augusta, 1902; died Aug. 1, aged 78, of heart disease.

Yadkowsky, Emanuel Ⓜ Newark, N. J.; University and Bellevue Hospital Medical College, New York City, 1903; served on the staff of the Beth Israel Hospital, where he died Aug. 23, aged 74, of a heart attack.

Young, Harry Hopple, Robertsburg, W. Va.; Medical College of Ohio, Cincinnati, 1900; veteran of World War I; first director of the George Washington Life Insurance Company in Charleston; one of the founders of the original Charleston General Hospital; died in Charleston General Hospital Aug. 28, aged 80.

BRAZIL

Exfoliative Cytology of the Stomach.—Dr. Flavio San Juan compared the value of chymotrypsin lavage with the results of x-ray examination, gastroscopy, and estimation of gastric acidity in 82 patients (*O hospital* 53:513, 1958). The patients were divided into four groups: a control group of 20 with radiologically normal stomachs, 15 with peptic ulcers, 23 with benign nonulcerative lesions, and 24 with malignant neoplasms. In 77 patients (93.9%) the results of cytology were correct; in 3 (3.7%) they were inconclusive; and one patient gave a false-positive and another a false-negative result. The results of radiology were correct in 63 patients (76.8%), false-positive in 9 (11.0%), and inconclusive in 10 (12.2%). Gastroscopy, performed in 43 cases, gave correct results in 38 patients, or 88.4%. In the control group with normal stomachs the results of cytology, radiology, gastroscopy, and gastric acidity were always in complete agreement. In the group with benign gastric ulcers the results were correct in 100% of the cytological examinations, in 80% of the radiological examinations, and in 71.4% of the gastroscopies; but for the exact diagnosis, radiology had the first place, followed by gastroscopy. For the determination of the benign or malignant nature of the lesion, cytology was superior to other methods. Gastric acidity was the least valuable. Gastroscopy was the best method for diagnosing chronic gastitis in general, followed by cytology and gastric acidity as the best means of diagnosing extensive atrophic gastritis. Radiology was the best method for other types of benign lesions. In the investigation of the possibility of malignant transformation of benign lesions, cytology was the most accurate.

In the group with malignant neoplasms of the stomach, cytology gave correct information in 87.5%, followed by radiology (79.1%), and gastroscopy (76.9%). In this group cytology and radiology together gave the correct diagnosis in 91.7%, and when cytology, radiology, and gastroscopy were combined, a correct diagnosis resulted in 100%. In six patients in whom the diagnosis of cancer was made in an early stage, cytology gave correct information in all, radiology in 4, and gastroscopy, carried out in only three patients, gave one false-negative result. There was no correlation between the degree of malignancy and the cytological findings.

Broad-Spectrum Amebicide.—Amaral and Pires, (*O hospital* 54:75, 1958) treated a series of eight patients who were carriers of several species of intestinal amebas, including Entamoeba histolytica, with a new drug derived from phenantroline (preparation 11-925 C). After a seven-day treatment with 300 mg. taken three times a day, all amebas disappeared.

Hepatosplenomegaly in Children.—Dr. Denise Altenhein and co-workers of the São Paulo State University Hospital presented to the Associacão Paulista de Medicina a paper stressing the importance of the hepatosplenomegalic syndrome in children in diverse conditions with a certain pathogenic affinity. Icterus and anemia are frequent accompanying symptoms. In their series of 116 patients the abundance of signs, symptoms, and laboratory findings demonstrated the probable impossibility of making a diagnosis on the basis of hepatosplenomegaly alone, because such enlargements may be vascular, inflammatory, infiltrative, or tumoral. Anyway, it serves at least as a starting point for the diagnostic deductions. The patients were classified as having (1) diseases of the liver, including cirrhosis and malformations of the biliary ducts (32 patients); (2) diseases of the blood such as hemolytic anemias, leucemia, and reticuloendotheliosis (31 patients; (3) congenital syphilis (24 patients); (4) infections and parasitic infestations, including leishmaniasis and schistosomiasis (11 patients); and (5) vascular accidents such as thrombosis (4 patients). There were 14 cases of errors and omissions of diagnosis, including two patients with sympathoblastomas with metastasis in the liver.

FRANCE

Aortography.—P. Betoulières and co-workers (*Montpellier Médical*, vol. 52, no. 2, 1957) used a trocar with a short-bevel needle, a mandrel for obturation, and a sounding line fitting into a metallic conductor for aortography. As one passes the sounding line along the metallic guide in the trocar, an assistant injects a small quantity of a contrast medium to make sure of the exact location of the sounding line. The aortic tree may be made opaque by this method from the aortic arch to the iliac bifurcation. To visualize an arterial branch, bent sounding lines are used. The advantage of this method lies in the possibility of injecting the contrast medium at the de-

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

sired height and in the fact that a minimum of the medium is required. The technique presents no danger; it is safer than the usual method of aortic angiography.

Treatment of Drowning.—L. Fournier at the Concours Médical in March described a new treatment of drowning consisting of (1) parilaryngeal infiltration with a local anesthetic to stop spasm, (2) laryngeal intubation, and (3) precordial massage or intracardiac injection with epinephrine or arterenol.

Emergency Treatment of Corrosive Esophagitis.—Flottes and co-workers (*Annales d'oto-laryngologie*, March, 1958) treated a series of nine patients who had corrosive esophagitis with cortisone and ACTH. In each case a swallowed thread acted as a guide on which a sound could be passed. The thread was introduced through the nose and retained for at least one month or until cicatrization was complete. Thus alimentation was maintained without gastrostomy. This method permits the physician to follow the course of the cicatrization. Eight patients recovered without sequelae. The one failure was due to introducing the guiding thread too late.

Carcinogenesis.—In the *Bulletin de l'Association Française pour l'Etude du cancer* (vol. 44, no. 4) Lacassagne and co-workers reported a series of experiments comparing the cancerogenic action of cellophane, graphite, and mica. The authors found that sarcomas were produced in those rats in which a leaf of cellophane was wrapped around the kidney. In those with inclusions of mica and graphite no tumors developed, but a lamella of glass produced a fibrosarcoma.

Treponemic Antigens.—Vaisman and Hamelin (*Presse méd.* 66:1397, 1958) stated that the serodiagnosis of syphilis has been facilitated by new methods making use of treponemic antigens in contrast with classic tests which use lipidic reagents. Hemolytic reactions with Ritter's treponemic antigen are more sensitive and more specific than those with the lipidic reagents but are difficult to perform. Hemolytic reactions with pathogenic Treponema pallidum as antigen (Portnoy's and Magnuson's antigen) gave results approximating those obtained from the Treponema immobilization test. The antigen is very stable. The adhesion-disappearance reaction consists in adhesion to human erythrocytes of the treponemas sensitized by the specific antibody in the presence of a complement. The test is difficult to evaluate. The Treponema immobilization test is already widely used. The authors concluded that it is the best because of its high specificity and great sensitivity.

INDIA

Coronary Disease.—A study of coronary heart disease by Malhotra and Pathania (*Brit. M. J.* 2:528, 1958) does not support the commonly held view that it is less frequent in Eastern countries and that it is associated with a high fat intake. Data on 867 patients with coronary heart disease in the Punjab were collected from 3,054 patients with cardiac disease. Thus, coronary disease accounted for 28.4% of these. The maximum incidence of the disease was in the 50-to-59-year age group, which is a decade younger than the age group of maximum incidence in Western countries. In Western countries women suffer much less than men from coronary disease. The sex ratio in the literature varies from 1:4.2 to 1:6.6. In the Indian series the ratio was much the same, namely 1:6.7; yet in India women lead a comparatively sheltered and indoor type of life, and they are mostly vegetarians, nonsmokers, and teetotallers. The fat content of the diet taken by most of the Indian patients was low, compared with American and European standards; yet the incidence of coronary disease would appear to be of the same order. The authors found it difficult to believe that dietary fat could play any significant part in the causation of coronary disease. Their observations showed that vegetarians living on a low fat diet are no less likely to develop coronary disease than meat eaters. Tobacco did not appear to be a factor, as one half the patients were Sikhs, whose religion forbids smoking. They were no less susceptible to coronary disease than Hindus, whose religion does not proscribe it. Obesity has long been recognized as an associated factor in coronary disease. This was found to be so only in Indian women.

Patients were classified according to their socioeconomic status. The incidence of coronary disease was highest in the middle classes, intermediate in the upper, and least in the lower classes. As in Western countries those leading a "chairborne" life showed a higher incidence than those earning their living by hard physical work. The condition was far more common in the urban than in the rural population, but interpretation of the data obtained was difficult because the rural patient, unlike the town dweller, seeks medical advice only when he is severely disabled. A genetic factor plays a prominent part in the cause of coronary disease, according to the authors, who found a family history of ischemic heart disease in 33% of the patients. As in patients seen in the West, it was found that hypertension and diabetes were commonly associated with coronary disease.

Osteoarticular Lesions in Smallpox.—K. S. Bose (*J. Indian M. A.* 31:4 [Aug. 16] 1958) stated that, although the incidence of osteoarticular lesions after smallpox is small, he observed 12 such cases in one year; 9 of them occurred in the subacute stage of the smallpox attack two to six months after desquamation of scabs, and 3 occurred 1 to 12 years after the attack. Those observed in the subacute stage resembled pyogenic arthritis and osteomyelitis. Affection of the elbow and bilateral involvement were common features. One patient developed a sinus formation followed by bony ankylosis. The radiologic appearance resembled a chronic pyogenic osteomyelitis, but the ends of bones were also involved. Small cystic changes and subperiosteal bone formation without sequestrums or marked necrosis and new bone formation were characteristic. Both the epiphysis and metaphysis were involved along with joints. One patient, however, showed isolated bone involvement, while sequestrums and typical changes of osteomyelitis were seen in the patient who had developed a sinus. Joint changes consisted of erosion of articular ends, periarticular soft tissue swelling, and increase in joint spaces.

In two late cases, growth at the involved joint was interfered with, although movement was preserved to a great extent. In late cases in general the joint space was decreased with deformed articular ends and unequal growth causing valgus deformity. Microscopic examination of aspirated material and biopsy of synovial membrane, muscle, and capsule showed a few degenerated cells but no microorganisms. Culture of the aspirated material was also sterile. On microscopic examination, the bones showed changes resembling those of osteitis fibrosa. Pure bone lesions healed after curettage and scraping. Partial excision of the elbow joint was performed on two patients, one of whom did well. One patient who had developed genu valgum was subjected to a corrective osteotomy and obtained a good result. Sequestrectomy was performed on the patient with sinus formation. In five patients with comparatively early changes and swollen elbow joints, the joints were immobilized in plaster. A gradual improvement in movement of the joints with no recurrence was met with, although the movements of the elbow were not restored completely in any case.

Mental Deficiency.—Manchanda and Sagar (*Indian J. Child Health* 7:7 [July] 1958) reviewed 200 cases of mental deficiency in children and found that idiopathic mental deficiency accounted for 71.5%. About 50% of the rest gave a history of meningitis or encephalitis. Of the 200 children, 140 belonged to the poorer class; 77 came from rural areas, and the rest came from cities. The number belonging to the age group 0 to 1 was smallest, and about 67% were aged 2 to 5 years; 42.5% of the children were either first or second born and most of these were in the idiopathic group. Of the 69 mothers above 30 years of age, 26 were mothers of children with mongolism; thus 74.3% mothers of the 35 with mongolism were above 30 years of age. There were 184 children born full term, 15 were premature, and 1 was postmature. Thus prematurity was not a major factor in the causation of mental deficiency. A history of difficult labor was available in 44 cases, and 28 mothers had had some illness during the antenatal period, the commonest being fever of short duration. One had jaundice due to infectious hepatitis. One mother confessed attempted abortion. A family history of mental illness and epilepsy was obtained from only four patients, and none gave a history of consanguinity. Nineteen of the children had difficulty in breathing and cyanosis soon after birth; 11 of these had cerebral palsy, 6 had jaundice in the first week, and 6 had epileptiform fits in the neonatal period. Trauma, infection, and malnutrition occurred after birth in 31. The presence of mental deficiency was suspected by the parents of only 25% of the children below the age of 2 years. Most were brought to the doctor for some physical defect such as rickets, flat feet, or general debility. The idiopathic group included those with mongolism and microcephalics. This series did not contain a single case of congenital syphilis, although serologic tests for syphilis were made in all suspected cases. According to mental tests, 77 were idiots, 110 imbeciles, and 23 feeble minded; 107 were difficult and unmanageable.

Clinical Trials with Chloramphenicol.—S. M. Merchant (*Indian J. Child Health* 7:8 [Aug.] 1958) gave chloramphenicol monostearoylglycolate-3 to 77 children with various infections. The ester was found to give the same blood level as that obtained by administration of free chloramphenicol in animal experiments and in tests on human beings. The series included 29 patients with whooping cough, 21 with enteric infection, 16 with bacillary dysentery, and 11 with neonatal infection. Twenty-one of the 29 with whooping cough obtained excellent results, but in 3 there was no improvement; 4 developed mild diarrhea which did not call for withdrawal of the drug. All but two of those with enteric infection did well, the temperature returning to normal within 72 hours; four developed slight diarrhea. All of those with bacillary dysentery responded well, both the fever and diarrhea being controlled within 24 hours. Eleven neonatal patients with undiagnosed infection responded well.

Neomycin-Sulfadimidin for Infant Diarrhea.—Gupta and Pohowally (*Indian J. Child Health* 7:8 [Aug. 18] 1958) treated 40 unselected children under the age of 2 years for diarrhea with a suspension containing neomycin, sulfadimidin, pectin, and kaolin, and the results were compared with those obtained in a control group of 60 children also under 2 years of age who received sulfadiazine, chloramphenicol, or streptomycin, singly or in combination. Patients were considered cured when the number of stools was less than five in 24 hours, consistency was solid or semisolid, no blood or mucus was seen on macroscopic examination of stools, and microscopically there was no blood or mucus and less than two pus cells per high-power field. There was no difference in the incidence of diarrhea in breast fed infants and those reared on mixed or artificial feeding. In each group 55% obtained a five-day cure. Stool culture showed a predominance of Escherichia coli, and these patients responded well to the neomycin-sulfadimidin therapy. This combination, however, did not seem to have any advantage over the standard therapy for diarrhea.

Liver Function Tests.—K. H. Nair and co-workers (*J. A. Physicians of India* 6:3 [July] 1958) studied 52 patients with cirrhosis of the liver, congestive splenomegaly, hepatitis, and carcinoma of the liver in persons above the age of 12 years. The maximum age incidence was between 20 and 40 years. About 44 complained of anorexia and pain in the abdomen. Ascites was present in 29. The enlargement of liver varied from just palpable to five fingerbreadths below the costal margin. The spleen was also enlarged in about 10, and it was noticed that in all patients with associated splenomegaly, ascites was present. There was no relation between the size of the liver and the presence of ascites. The thymol turbidity test varied from 2 to 10 units and was not related to the degree of enlargement of the liver and presence or absence of ascites. In patients with a raised icterus index and a direct immediate Van den Bergh's reaction, it was above 7 units. The serum protein level varied from 6.0 to 10.2 Gm. per 100 ml., and variation in total protein levels were not related to the thymol turbidity test, Van den Bergh's reaction, and icterus index. The total serum protein levels were lowered in only three patients, but there was a change in the normal albumin-globulin ratio, the latter being raised. This ratio was not normal in any patient and varied from 1:1 to 1:3. The alkaline phosphatase estimation gave normal values, while the protein content of the ascitic fluid was found to be below 1.5 Gm. per 100 ml. The Kahn reaction was positive in 12 patients. The authors suggested that in addition to protein deficiency, exposure to infection and the stress and strain of life are probable etiological factors. Most of the patients with a high serum protein level and a diminished albumin-globulin ratio were highly toxic and even cholemic, the degree of cholemia being related to the increase in globulin. The case fatality rate was also higher in patients with a high globulin level.

Complications of Measles.—Silhar and Maru (*Indian J. Child Health* 7:7 [July] 1958) reported a series of 315 patients who had measles with complications. The maximum age incidence was seen in children between 1 and 2 years old, the youngest patient in the series being 4 months old; 80% were under 4. In this series 50% had respiratory complications; 30% had alimentary complications; and 6% had central nervous system complications. Otitis media, supposed to be a common complication of measles, was comparatively rare (less than 3%). Respiratory complications included bronchitis, bronchiolitis, bronchopneumonia, upper respiratory tract infection, and reactivation of pulmonary tuberculosis. Most of these occurred within the first 10 days of appearance of the rash. All the patients with bronchiolitis were under 18 months of age. While a combination of penicillin and streptomycin was found useful in the treatment of these complications, adequate doses of sulfonamides given in time were also effective. The main alimentary complications were enteritis, gastroenteritis, and dysentery. Stool examination was uniformly negative. Sulfadiazine, streptomycin, and chloramphenicol were useful in the treatment of these complications. The central nervous system complications included 14 patients with encephalitis, 3 with tuberculous meningitis, and 1 with a flare-up of febrile convulsions; 11 cases of encephalitis occurred within two weeks of appearance of the rash, 1 after three weeks of appearance of the rash, while in 2 it preceded the appearance of the rash. Other complications included skin infection in 10 and eye and ear infection in 10. As sequelas of measles, anemia developed in 14 patients and malnutrition in 8. The largest number of patients in this series came from treatment in the second week; 90% had had no treatment in the preeruptive or eruptive phase. There were three deaths, all occurring within 48 hours of hospitalization, two patients dying of encephalitis and one of tuberculous meningitis.

Effect of Soluseptasine on Blood Sugar.—Bhattacharya and Goswami (*Antiseptic* 55:7 [July] 1958) studied the effect of intravenous injections of Soluseptasine (a sulfonamide) on the blood sugar level of 50 men in hospital. Patients with liver, kidney, and heart diseases were excluded. A preliminary glucose tolerance test was done in all patients, four days later fasting blood samples were taken, and then 5 cc. of 20% Soluseptasine was given intravenously; 50 Gm. of glucose was given orally after the injection, and blood samples were collected every half hour for two and one-half hours and after three and one-half hours. Urine was also collected at half-hourly intervals and examined for sugar. Some urine samples in 13 patients showed sugar. The blood-sugar lowering effect of Soluseptasine was evident in 30 minutes and reached its maximum in one and one-half to two and one-half hours. Four patients showed signs of hypoglycemia, and two had only glycosuria. The authors suggested that a liberal supply of carbohydrates should be given to patients who are receiving sulfonamides intravenously.

Sanitary Engineering.—The government agreed to the payment of stipends, fees, and other expenses to sanitary engineers and auxiliary sanitary engineering personnel for training in the implementation of a national water supply and plans for sanitation. In the year 1958-1959 such stipends will be given to 45 trainees for training as engineers for a period of 10 months. Those taking the course will be eligible for the stipends from the date they join the course. Another group of 150 engineers will get stipends for a three-year course at the All-India Institute of Hygiene and Public Health, Calcutta, and the Engineering Colleges at Roorkee and Guindy, where stipends will also be given to 180 engineering subordinates for a three-year course. Other personnel who will be receiving assistance include 100 waterworks operators and 50 sanitary inspectors to be given short courses at various regional centers.

Tuberculosis.—In an address before the Tuberculosis Association of Madras in July, the minister of health said that about 500,000 persons died every year of tuberculosis and 2,500,000 were suffering from it at any given time in this country. The health panel of the planning commission had estimated that the needs of the country in this field at the start of the first five-year plan were 4,000 tuberculosis clinics, 500,000 beds, 15,000 physicians, 50,000 nurses, and 12,000 home visitors. The gap between the needs and the available resources could be seen from the fact that there were only 160 tuberculosis clinics and 7,000 hospital beds at the beginning of their planning. While it was necessary to increase these facilities, most of the emphasis must be on prevention rather than cure, on domiciliary services rather than hospital care, and on early diagnosis rather than on surgery. The transmission of the infection must be prevented through isolation at home as well as hospital treatment. There is a great need for voluntary assistance in this sphere. The Tuberculosis Association of India, a voluntary organization, has done a great service in this connection. Public interest has been awakened to the importance of the problem.

Epidemic Encephalitis.—In Nagpur, with a population of 500,000, between June 26 and July 4 there were 20 children between 1 and 10 years of age admitted to hospital (*Indian Journal of Child Health*, Aug., 1958). All 20 died. Some gave a history of acute diarrhea, vomiting, dehydration, and convulsions; others had hyperpyrexia, vomiting, and convulsions. Death occurred within 24 hours of admission. Children with this disease admitted between July 4 and 8 were not as sick, and some survived. All of those admitted after July 8 survived. The admission rate then declined rapidly. Similar cases were also seen in private practice, but their mortality was low, one death being reported in 24 cases. Physicians reported having seen such patients almost every year at this season, although their number was smaller and the treatment was mostly symptomatic. At the hospital, these children received chloramphenicol routinely, and those that survived could be discharged on the third day. The only neurological sign in these patients was muscular rigidity of the neck and back. The spinal fluid showed no definite abnormality, and blood, stool, and urine specimens and throat swabs revealed no causal organism on culture. The cause could be a virus. No residual paralysis or any other neurological sign was seen in the survivors.

UNITED KINGDOM

Triamcinolone.—A clinical trial with a new Δ^1 cortisone analog containing fluorine (triamcinolone) was made by Hart and coworkers (*Lancet* 2:495, 1958) in 30 patients with rheumatoid arthritis, systemic lupus erythematosus, and ulcerative colitis to compare it with prednisolone and ascertain its side-effects, particularly those affecting the stomach. The dose of the drug was four-fifths that of the prednisolone given previously. All the patients with rheumatoid arthritis kept daily records of pain, stiffness, the number of analgesic tablets needed daily, and the time it took to loosen up in the morning on rising. Observations were also made every three or four days of joint tenderness in the fingers, finger swelling, and strength of grip. The sedimentation rate was determined weekly. Of the 25 patients with rheumatoid arthritis 11 improved, but in only 5 was improvement more than slight; 11 preferred triamcinolone to prednisolone. Of seven patients who complained of dyspepsia while taking prednisolone, three improved when they changed to triamcinolone and three were made worse by the change. The condition of the patients with lupus erythematosus and ulcerative colitis was unchanged after being given triamcinolone.

The authors concluded that triamcinolone is another effective steroid with no particular therapeutic virtue, except that it does not cause salt and water retention. One of the side-effects noted was postprandial flushing. Wells gave the drug to 14 patients, previously maintained on therapy with prednisolone, for various conditions (*Lancet* 2:498, 1958). Of nine with no previous history of joint symptoms, three developed arthritis, which in two resembled acute rheumatoid arthritis. He suggested that the change of therapy from one steroid to another was responsible. Apart from this episode, he considered the therapeutic effectiveness of triamcinolone to be superior to that of prednisolone.

CORRESPONDENCE

TOXICITY AND ANTIPYRETIC ACTIVITY OF SALICYLAMIDE AND ASPIRIN

To the Editor:—In The Journal of Aug. 9, 1958, page 1821, the article "Antipyretic Effectiveness of Salicylamide and Acetylsalicylic Acid in Infants" by Vignec and Gasparik contains a number of misleading statements. These become even more disturbing after the reading of their references and the pertinent literature.

The authors say: "Actually, if one can extrapolate from the observed LD_{50} for mice . . . it is difficult to see how a child might ingest dangerous amounts [of salicylamide]." This extrapolation is then accepted as a scientific fact, because in their conclusions they state that "the greater margin of safety of salicylamide must also be taken into account." The authors refer to Seeburg and others (*J. Pharmacol. & Exper. Therap.* 101:275-282 [March] 1951) as their basis for stating that the LD_{50} of salicylamide is "approximately twice that of aspirin." Actually, Seeburg presents no data on LD_{50} in this article.

Table 1.—*LD_{50} Values in Mice, in Grams per Kilogram of Body Weight, After Ingestion of Salicylamide and Aspirin*

	Salicylamide (SAM)	Aspirin (ASA)	Ratio SAM:ASA
Drebinger (Medizinische 7:795-797 [June 7] 1952)	1.14	1.87	0.61
Carron and others (Therapie 7:27-36, 1952)	0.60	0.83	0.75
Hart (J. Pharmacol. & Exper. Therap. 89:205-209 [March] 1947)	1.40	1.10	1.27
Bavin and others (J. Pharm. & Pharmacol. 4:872-878 [Nov.] 1952)	1.39	1.30	1.22
Boxill and others (J. Am. Pharm. A. Scient. Ed. 47:479-487 [July] 1958			
Fasting	1.20	0.96	1.26
Nonfasting	1.50	1.00	1.50
Matsumura (Fol. Pharmakol. Japan 50:60, 1954 [From Bekemeier, Arzneimittel-Forsch. 5:572-575 (Oct.) 1955])	1.15	0.75	1.53

A search of the literature discloses six reports (table 1) on the oral LD_{50} values in mice in grams per kilogram of body weight. Two of the reports show salicylamide as the more toxic, and four show aspirin as the more toxic. However, in no case is aspirin reported to be twice as toxic.

Justification for the statement that aspirin is approximately twice as toxic as salicylamide has not been found, even when a thorough search of the literature was made for all species. Oral LD_{50} values reported for the rat, rabbit, guinea pig, and cat in grams per kilogram are shown in table 2.

It can be seen from these values that the relative toxicity of salicylamide and aspirin administered orally varies in the same species under different conditions and in different species. In rats, two authors found salicylamide to be more toxic and two others found aspirin the more toxic. Oral LD_{50} values in cats show that salicylamide is approximately three times as toxic as aspirin; while on the other extreme in the rabbit salicylamide is reported as approximately 0.6 as toxic as aspirin. It is difficult to see how any extrapolations from these reported values in animals could provide a valid relative toxicity ratio for humans that would show one drug to be less toxic than the other.

Table 2.—*LD_{50} Values, per Kilogram of Body Weight, in Experimental Animals*

	Species	Salicylamide (SAM)	Aspirin (ASA)	Ratio, SAM:ASA
Hart (J. Pharmacol. & Exper. Therap. 89:205 [March] 1947)	Rat	1.40	1.50	0.93
Boxill and others (J. Am. Pharm. A. Scient. Ed. 47:479-487 [July] 1958)	Rat	0.98	1.43	0.68
Drebinger (Medizinische 7:795-797 [June 7] 1952)	Rat	1.49	1.24	1.20
Ichniowski and Heuper (J. Am. Pharm. A. Scient. Ed. 35:225-230 [Aug.] 1946)	Rat	>2.00 2.00	>2.00 1.00	1.00 2.00
Boxill and others (J. Am. Pharm. A Scient. Ed. 47: 479-487 [July] 1958)	Guinea pig	1.73	1.07	1.60
Hart (J. Pharmacol. & Exper. Therap. 89:205-209 [March] 1947)	Rabbit	>3.00	1.80	>1.69
Bekemeier (Arzneimittel-Forsch. 5:572-575 [Oct.] 1955)	Cat	0.1-0.15	0.40†	<0.25 to 0.37

---

* The widely different results reported require clarification.

† Value of 0.4 is for salicylic acid which is more toxic than aspirin.

The statement of Vignec and Gasparik, in their summary and conclusions, that "a comparative study of the effectiveness of salicylamide (Liquiprin) and acetylsalicylic acid (aspirin) indicated that both drugs controlled pyrexia . . . equally well and with the same number of doses," is extremely misleading. Though approximately the same number of doses were required, each dose of salicylamide was twice that of aspirin. Therefore, twice as much salicylamide was administered over the same period of time. With evidence that salicylamide and aspirin are each more toxic than the other under certain conditions and in certain species, the use of twice the dose of salicylamide in their study would appear to be the more hazardous procedure. Actually, the doses of salicylamide used in their study were two to three times the recommended doses as stated on the label and package (table 3). No explanation was given for the use of these larger doses.

Table 3.—*Doses as Used by Vignec and Gasparik and as Recommended by Manufacturer*

Age	Dose, Mg.		Ratio, Dose Used: Dose Recommended
	Used	Recommended	
0-6 mo.	64	20	3.2
6-12 mo.	128	60	2.1
1-2 yr.	256	120	2.1
2-3 yr.	384	200	1.9

It is well known that the temperature of children is quite labile and that fever "breaks" and disappears spontaneously in many instances. The absence of any control untreated children in the study is indeed unfortunate. The many items cited above justify withholding judgment on the comparative toxicity and antipyretic activity of aspirin and salicylamide until adequately controlled studies are available.

Memphis 3, Tenn.

PATHOLOGIST'S DEATH CERTIFICATE

To the Editor:—An interesting and timely article, "What Is 'the Cause of Death'?" by Erhardt, appeared in THE JOURNAL (168:161-168 [Sept. 13] 1958). The author is primarily making a plea for accurate death certificates so that they can have valid meaning in compiling scientific, medical, and public health reports. He states, "Solely the physician in attendance, therefore, can judge adequately which of several conditions was the most important factor in the death of the patient."

As a pathologist, I wish to challenge the validity of this statement and to offer some constructive suggestions. Many people die without benefit of medical attendance except terminally, especially when death is sudden, as it often is. Many people change physicians for their terminal illness, calling in the nearest physician or the first physician they succeed in contacting. Many patients are transferred from the neighborhood physician to a strange physician in a nearby hospital for their terminal illness. Many people die and are certified by coroners who are sometimes laymen and often without benefit of autopsy. People move to new communities and have new doctors. It is said that one-fifth of the population of the United States moves to a new home each year.

Even when people die in hospitals and have been fully and adequately studied, the cause of death, as certified, is incorrect in a high percentage of cases when there is no autopsy. The accuracy of "the cause of death" as determined by clinical findings alone is probably no greater than 40%, a charitable estimate. There are many possible discontinuities in the clinical study of a patient which cannot always be avoided.

The point is that death certificates are not very accurate and cannot be expected to be very accurate even under the highest standards of present-day clinical practice. I have known of instances where the physician did not know the cause of death and freely admitted this. Coroners usually refuse autopsies on this ground alone and inform the physician to make the best guess he can, which usually turns out to be "heart failure."

There is only one effective way to make death statistics accurate and that is to base them, where possible, on the findings of autopsies performed by competent pathologists. The large mass of accurate autopsy data which is accumulated in hospitals today is mostly wasted as far as death statistics are concerned.

Question No. 20 on the standard death certificate —Autopsy? Yes, No—is of little help. The inference is that if there was an autopsy, the death certificate was completed on the basis of the autopsy findings. This is not necessarily so. The physician is not required to use the autopsy findings and frequently does not do so. The death certificate is sometimes completed when the person is pronounced dead, without waiting for autopsy findings and without knowing whether there will be an autopsy. In some places, this is standard practice and is encouraged or enforced by administrative rule. In addition, "the death certificate cannot wait." It must be completed promptly for the convenience of the funeral director and the survivors so that prompt funeral arrangements and burial can be made. It may take several days or even weeks to complete the scientific autopsy studies.

If the states, the public health people, and the vital statistics workers want accurate death statistics they can have them and they can have them in abundance. Supplemental death certificates, which might be called "Pathologist's Death Certificates" should be legally authorized. Pathologists should be required to complete such certificates for all autopsies that they perform and submit them to the vital statistics officer concerned within a reasonably limited period of time, such as 60 or 90 days.

A legislative program such as this would produce a large volume of highly accurate data on the causes of death and should, in the long run, result in many scientific medical advances. At least, we would have an accurate scientific picture of what the most important medical problems are. Autopsies do not always disclose the true cause of death, but their accuracy, when they are properly performed, is about 98 to 99%.

Today, the pathologist completes his scientific labors in his rather highly accurate field of work, writes his report, and finds it buried in the hospital record room, just as effectively buried as the body on which he performed the autopsy. A small percentage of these reports are used locally for teaching purposes. A still smaller percentage, usually the rarest cases, are published.

The supplemental death certificate is not without precedent. They are used in a limited way in a few jurisdictions. It is my understanding that the city and county of San Francisco started using such certificates on an optional basis many years ago. There should be a separate and mandatory "Pathologist's Death Certificate" in all cases of autopsy. Such a death certificate might occasionally cause embarrassment to a few physicians. It should be no greater than that which tissue committees now cause occasionally in the case of surgeons. Any small individual embarrassment would be a small price to pay where the greater public welfare is at stake. When the realities of the matter are studied, there should be no embarrassment at all for any physician. In the present state of development and utilization of medical science, no physician should be expected to have an omnipotent ability to determine "the cause of death."

THE LEISURE CORNER

GEMS AND PRECIOUS STONES

During periods of peace and prosperity gems and precious stones have many purchasers. All minerals and stones that are used for jewelry and other ornamental purposes are called gems. During war and depression the more valuable gems are sold, traveling from one owner to another and from one country to another. Historically speaking, there seems to be an interrelation between war and jewelry. Centuries ago warriors frequently carried their jewels with them into the thick of battle. Not too long ago the royal sale of jewels and precious stones provided funds for the conduct of war, while private individuals sold their gems so that they might survive. It still works both ways today—for martial governments on the march and for ordinary mortals. Heirlooms cherished for generations by families often find methods and means for entering exclusive shops on Fifth Avenue—the purpose, of course, to be sold. War has a characteristic way of poking greedy fingers into jewel boxes and then tossing the loot where it may.

Hardness, color, brilliance, rarity, and demand determine the value of gems. As a rule, diamonds are prized gems because they surpass all others in hardness and brilliance. Probably the most famous and celebrated diamond in the world is the Kohinoor, which was presented to Queen Victoria, in 1850, by the East India Company. The Cullinan diamond was famous because it was the world's largest at one time, weighing a little over 1.5 lb. before it was cut into 2 large stones, 7 smaller ones, and 96 others of lesser size. The largest of these, the 530-carat Star of Africa, is among the crown jewels of England and is set in the royal scepter.

A diamond of the highest degree of purity and fineness is said to be "of the first water." Color is the most important factor in judging a diamond. Those of the finest quality are perfectly clear. Some varieties of diamonds are green, orange, red, yellow, or blue. The most valuable ones are those in which the tint is decided and equal throughout. Even the lightest tint of a different color in a diamond affects its commercial value unfavorably and the finest gems can be spoiled by poor cutting. Rubies are more valuable than sapphires because they are rarer, although both have the same degree of hardness. The value of sapphires depends on the quality of their blue color. The emerald is often as valuable as the diamond, and its value is determined by size, freedom from flaws, and the shade of the green color. Pearls are graded by size, color, and perfection of shape, while opals are valued according to their color flashes. The so-called black opals are the most valuable.

In general, experts identify different kinds of gem minerals by the shape of the uncut crystals, color, index of refraction, hardness, specific gravity, and other properties. The shape of crystals differs with each gem material, but the shape of all crystals in any one mineral is usually the same. Color is one of the major factors in determining the beauty and splendor of gems. There are two types of colors in gems, essential and nonessential. Essential color is the color of the mineral itself, when pure, while nonessential color is the result of an impurity in the mineral. Minerals with a low index of refraction (the measurement of the speed of rays of light passing through a mineral) usually display a low luster. Hardness is an important quality of gem minerals. Few stones can become valuable gems unless they will wear for a long time. A scale has been established to indicate the sequence of hardness of each gem material, and it numbers from 1 to 10. Only minerals with a rating of seven or more wear well as gems. The diamond is the hardest and has a rating of 10.

The underlying rock type is the prime factor largely determining the kind of gem minerals found all over the world. Turquoise is found in great quantities in the southwestern part of the United States as well as in Tibet. Opal and turquoise are found where there is little rainfall. Emerald, topaz, and tourmaline are found in areas where erosion has exposed old, once molten rocks at the surface. Emeralds are found in the Ural Mountains, Colombia, and South Africa, while the finest topaz comes from Brazil. The best rubies come from Burma and the best sapphires from Kashmir. The finest opals come from Australia, and the most desirable pearls are derived from the waters of the Persian Gulf and the South Pacific Islands.

The beauty of a gem stone depends largely on its luster; hence, the appearance of a gem is somewhat equivalent to the texture of a flower. As a matter of fact, the word gem comes from the Latin word gemma meaning bud, and the story of precious stones can be compared to the blooming of flowers. An authority on gems recognizes the following eight different types of luster: (1) adamantine: a luster characteristic of diamonds; (2) vitreous: having an appearance of broken glass (as sapphire, ruby, topaz, tourmaline, and rock crystal, which are all transparent, vitreous in luster); (3) metallic (only opaque gem stones, for example, hemetyte and pyrite); (4) pearly: like a pearl (as moonstone and opal); (5) waxy (as turquoise); (6) resinous (as garnets); (7) silky (as green malachite); and (8) oily (as chrysolite).

The craftsman—sometimes a painstaking hobbyist—who cuts, polishes, and engraves gems is known as a lapidary. The word itself is derived from the Latin word lapis, meaning stone. Lapidaries flourished in Assyria and Babylonia several thousands of years ago. A sapphire point was used in cutting until about 3,000 B. C., when the bow drill was introduced. Contemporary gem cutters employ a lathe with a point or disk of soft iron, coated with diamond dust and oil. Before the 1300's most gems were polished smooth and closely retained the original size and color of the stone. The practice of cutting flat surfaces or facets is fairly modern.

Since nature yields her precious stones reluctantly and only the comparatively well-to-do may own them, the craving for gems has gone on for centuries. This, in part, has been satisfied by the glassmaker, the alchemist, and the chemist. Imitation gems have a wide market. Today, the basis of most imitation gems is a soft glass called paste or strass. This glass is clear and brilliant, and is made of pure powdered rock crystal, red lead, and dry potassium carbonate. Imitation gems made from this paste can be scratched easily. White sapphires, colorless zircons, and clear quartz make inexpensive substitutes for diamonds. An old-time formula for making a sapphire reads as follows: "Take a crystal, 1 lib., grind it very fine and sift it, afterward put ½ lb. of the powder of stags bones burnt, if you can procure them, if not of other animals, or sal. alkali lib. ½, grind all very fine, and mix them well together. Take this powder and put it into a strong pot, covered and luted outside; when you have cooked this in a glassmakers' furnace, allow it to remain for 5 or 7 days, and it is there melted like glass. Afterwards place good 'azurio ultramarino' (made from lapis lazuli) and being mixed together will make the beautiful blue tone for making sapphires." Certainly, the old-timers had a formula for it.

Today, the chemist does not go in for hunting a stag and burning its bones to assist him in creating artificial gems. In recent years, synthetic gems of good quality have been produced in the laboratory. Rubies and sapphires have been made with chemical and physical properties that simulate the original. Nonetheless, the artificial gem cannot qualify as a true gem. Nothing can take the place of a mineral that nature has formed, unassisted by chemists. The dominant qualities that stand out in a true gem include outstanding beauty, sufficient hardness to retain that beauty, and the rarity that only the wonders of nature can produce.

BUSINESS PRACTICE

This is the fourth in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

LOCATING THE OFFICE

The next action a doctor must take who has selected his community and checked into licensing questions is to find an office. He has to decide whether to build, remodel, or rent space.

Building an Office

Although the idea of planning the ideal medical office from the ground up is appealing, few doctors starting out in practice have enough money to do so. Some doctors think it is wiser to practice in a community and definitely determine practice needs before building. Too often a doctor who has hurried into building programs discovers later that the office meets neither his nor his patients' needs.

For the physician who can build his own office there are some words of advice: 1. Consider the most ideal location from your standpoint as well as the patients' standpoint. 2. Check with a reliable realtor about property availability. 3. If the building site is in a residential zone, check with the zoning commission to find out if medical offices are allowed. 4. Make sure the sewer, water supply, electric service, telephone service, and gas service are adequate. This is particularly vital in suburban areas. 5. Get the consulting services of an architect to help make the final decision about purchase of the property. Utilize his services in design of the proposed building. (In most communities services of a member of the American Institute of Architects can be secured.) 6. Building an office is a business venture, involving expenditure of considerable cash. The whole process should be conducted in a business-like manner with the aid of experts secured to make sure it is a sound investment.

Renting an Office

The doctor who decides to rent is sometimes limited in the selection of a location by what space is available. In the suburbs and smaller towns adequate office space may be hard to find. He probably will be offered these possibilities: space in a downtown medical center or office building, a suburban location, or a combination home-and-office arrangement (see table).

It is best to analyze all the possibilities in terms of the kind of practice envisioned and the doctor's own personal desires.

Office Essentials

In deciding on an office location, there are several factors which should serve as a yardstick. Is it accessible and convenient from the patients' standpoint? Obviously, if it is six blocks from the end of the bus line or if patients have to run outside to deposit pennies in a parking meter every few minutes its location leaves something to be desired. Is it adequate space-wise and convenient from the doctor's standpoint? The beginning doctor generally can manage with a reception room, examining room, and consulting room for the first year, but he soon will need more room. If the layout of the office is inconvenient for the physician, he'll waste valuable minutes and tire himself out working in it. It probably is wiser to take a long-range approach to selection of an office location and pay rent on an extra room or two at the outset rather than try to secure more space later or move to a new location.

The less remodeling required, the better. However, remodeling is sometimes a quick, easy, and fairly inexpensive way to establish a new medical office unit. Store buildings and large residences often can be converted into medical offices with a fairly small original investment. The feasibility of remodeling should be determined only after consulting experts—builders and architects who can appraise the structure, the adequacy of heating, plumbing, electrical systems, and the possibilities for efficient office layout.

A physician who remodels or makes minor alterations in leased or rented space should protect himself with a long-term lease, since all the money he invests is the landlord's gain. If the landlord pays for improvements, the cost shows up in higher rents. If the tenant pays, he can amortize the investment over the period of the lease for tax purposes.

Office Planning Guide

A detailed planning guide for establishing medical practice units, complete with checklists for evaluating possible office locations, plans for various types of offices, and lists of necessary equipment, is available to physicians on loan from the American Medical Association's Council on Medical Service. The U. S. Public Health Service also has available an office planning guide for physicians.

Plan carefully when setting up an office. The kind of practice and the speed with which it is built depend to a large extent upon the location and arrangement of the office.

Leases

"Look before you lease" is good advice for any tenant. It pays the physician to go over a lease line by line, preferably with an attorney, so that he knows exactly what he is signing.

Every lease should contain a description of the premises, including rooms and other storage space, and list any furnishings to be provided with a description of their condition. It should stipulate what services are to be furnished by the landlord in the way of utilities, janitor, and elevator service (if any) and who pays for decorating, alterations, and the expense of restoring the premises to their original condition when the doctor moves out.

Pros and Cons of Office Locations

Pro	Con
Downtown Medical Center	
Space designed for M.D.'s usually available Other M D.'s available for referral; good for specialists Auxiliary medical services available nearby	May be costly, cramped Patients may not be able to find a doctor marooned in a downtown "ivory tower" Parking space may be difficult to obtain
Neighborhood or Suburban	
Good for GP's, internists who draw patients from the area; more specialists also settling here Space for parking usually available May not be many other doctors in the area Office can be more home-like, informal	Space may be at a premium or available offices may need extensive remodeling May not be near public transportation; not all families have two cars Neighborhood may appear to be good but beginning downhill slump May have to settle for upstairs office which is not ideal for patients
Home and Office Combination	
Saves time and money	Seldom satisfactory, not enough privacy for patients, and doctor never escapes from practice; check zoning

Provisions should be included for subletting part or all of the premises in the event that the physician is unable to continue as a tenant. The doctor should also be relieved of any further liability should another tenant be assigned the lease. A right to terminate the lease is also advisable should a physician find it necessary to move for professional or other reasons.

An option to renew, specifying that the notice to renew the lease must be in writing, and submitted on or before a certain date, is a definite advantage to the doctor. Another possibility to consider is this: in leases covering more than three years it sometimes can be arranged that the monthly rental to a doctor just setting up practice is lower during the first year with the difference made up by higher monthly rentals later. Sometimes a landlord, anxious to secure a doctor-tenant, will provide a month or two of free rent. All possibilities should be investigated before signing, and any verbal promises should be put on paper.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Aplastic Anemia: An Analysis of 50 Cases. D. N. Mohler and B. S. Leavell. Ann. Int. Med. 49:326-362 (Aug.) 1958 [Lancaster, Pa.].

The authors studied 50 patients with aplastic anemia, their ages ranging from 4 to 82 years, at the University of Virginia Hospital in Charlottesville between 1933 and 1956. All the living patients have been followed for at least a year, and only 2 have been lost to follow-up. The other 35 were followed until the time of death, and autopsies were performed on 14. The peripheral blood and bone marrow of each patient were examined, and in each instance there was evidence of defective blood production. Patients were excluded from this study if they had chronic infection, malignancy, malnutrition, renal disease, or liver disease, conditions known to depress bone marrow functions, or if they had been treated with agents such as nitrogen mustard derivatives, urethane, and irradiation. Patients with myelofibrosis and myeloid metaplasia were also excluded. The most common symptom was weakness associated with a bleeding tendency, such as epistaxis, menorrhagia, and bleeding from the gums. All the patients with hemorrhagic manifestations had thrombocytopenia, but not all the patients with thrombocytopenia had abnormal bleeding. Most of the patients had pancytopenia, macrocytic anemia, relative lymphocytosis, and hypocellular bone marrow. However, in 13 patients the bone marrow was normocellular or hypercellular, and 7 patients had anemia that was not associated with leukopenia or thrombocytopenia. Although the most important factor in the anemia in these patients was deficient erythrocyte production, the presence of an associated hemolytic component, manifested by increased fecal urobilinogen excretion and mild reticulocytosis, was not unusual. Exogenous hemochromatosis was found in 6 of the 14 patients on whom autopsies were conducted. Brownish-gray skin pigmentation, lymphadenopathy, hepatomegaly, and splenomegaly occurred commonly in patients who received multiple transfusions. Toxic exposure was thought to be the etiological agent in 7 patients, while the cause was unknown in 43.

The prognosis was most favorable in patients with anemia alone and in those with hypercellular bone marrow. However, an illness of long duration was not uncommon in those with pancytopenia and hypocellular bone marrow. Although 12 of the 37 patients who presented with pancytopenia died within a year, 6 lived more than 5 years and 1 survived 20 years. A complete remission occurred in 6 patients, and a partial or temporary remission in another 6 patients. Both the spontaneous remissions and those that followed corticosteroid therapy and splenectomy occurred most often in patients who had anemia alone.

New Results in Treatment of Acute Leukemia with Metacortandracin. R. Picard, J. Horeau, J. Guillon and C. Robin. Presse méd. 66:1064-1067 (June 14) 1958 (In French) [Paris].

The authors present a follow-up of 6 patients with acute leukemia, whose cases were previously reported (*Presse méd.* 64:301-302 [Feb. 18] 1956, an abstract of which was published in THE JOURNAL 161:648 [June 16] 1956), and the results obtained in 19 additional patients, all of whom were treated with prednisone (Metacortandracin). The incidence of this disease in subjects less than 40 years was 70%; 18 patients died after periods of illness ranging from 4 days to 13 months. The average survival time was somewhat more than 4 months. The deceased patients were classified in 3 groups according to the duration of the disease; 5 with acute forms, who had a survival time of less than 1 month; 10 with subacute forms, who had a survival time of 1 to 6 months; and 3 with prolonged forms, who had a survival time of about 1 year. Two patients were lost to follow-up, and 5 patients are still alive. Of 2 surviving patients who have had remissions lasting several months, 1 is still alive after a follow-up of 20 months, and the other after 17 months. The other 3 living patients have had a follow-up of about 10 months.

The prednisone therapy was started with a standard dose of 100 mg. (larger doses of 250 or 500 mg. did not seem to be more effective), which was administered for 3 or 4 days and then gradually decreased by 10 mg. at a time until a maintenance level was reached in about 2 weeks. The mainte-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

nance dose was just enough to prevent reappearance of signs of the disease. This dose may be given, in principle, for an unlimited time. Prolonged treatments, lasting from 1 to 10 months, have been carried out by the authors in 12 patients. The current total doses in this series were of the order of from 5 to 7,000 mg. of prednisone. A record high of 12,000 mg. was given to 1 patient. Treatment had to be interrupted in only 2 patients.

The initial dose of prednisone was evidently of the greatest importance in regard to the restoration of a normal body temperature. It also had a good effect on the general well-being of the patients, except in those who died within a few days. Failure to obtain a good effect on the temperature by the treatment indicates a rapidly fatal outcome of the disease. Treatment with this drug, however, is not only ineffective but may even be dangerous in patients with fever of infectious origin; consequently, a careful and thorough search for a focal infection should be made, and in doubtful cases the systematic administration of antibiotics is advisable. Beneficial effects of the administration of prednisone on osteoarticular pain have been observed, except in a few patients with localized foci which, on the contrary, responded remarkably to local roentgenotherapy. The effect of the drug on the hematopoietic system is difficult to evaluate because of the almost constant use of transfusions. Nevertheless, definite improvement was obtained in the peripheral blood by prednisone alone, as shown by the values of both the red blood and the white blood cells. Complete normalization of the blood picture was even obtained in 2 patients. Stress must be laid on the excellent quality of the remissions from the functional point of view, which gave the patients a feeling of complete recovery.

A Toxic Agent in the Etiology of Leukemia. R. Scheuer-Karpin. Ztschr. ges. inn. Med. 12:416-423 (June 15) 1958 (In German) [Leipzig, Germany].

The author reports on clinical observations made on 40 patients with granulocytopenia or acute myelosis at the first clinic for internal medicine of the Hufeland Hospital in Berlin-Buch. Of these 40 patients, 14 had taken dimethylaminophenyldimethyl-pyrazolon (Pyramidon), 6 acetophenetidin (Phenacetin), and 8 various other medications, such as methylthiouracil, phenolphthalein, quinacrine hydrochloride (Atabrine), and analgesics. Twelve had taken no medication as far as could be determined. Examination revealed that toxic granulocytopenia and acute myelosis are always associated, since they have a common etiology. Granulocytopenia may develop into acute leukosis if the patient lives long enough. Hypercellular bone marrow with numerous immature forms in a patient with granulocytopenia is not a sign of regeneration, and the prognosis in such a patient is not favorable, for in most cases acute myelosis has been found later. The administration of Pyramidon in combination with other etiological agents can produce granulocytopenia and then myeloblastic leukemia. Phenacetin and its derivatives are suspected of causing similar blood dyscrasia.

Severe Effects of Influenza Virus Infection. J. A. Forbes, M. J. Australia 2:75-79 (July 19) 1958 [Sydney].

The Asian, type A, influenza epidemic in Melbourne, Australia, prompted the author to make a study of 672 patients admitted to Fairfield Hospital in that city during July and August, 1957. These patients showed clearly some of the relatively infrequent, more severe effects of influenza virus infection. Of the 672 patients, 169 had uncomplicated influenza, with a great variety of symptoms. About 120 of these complained of severe headache, often associated with generalized aches and pains, and in 31 patients the combination of headache and meningism was such that lumbar punctures were performed revealing normal cerebrospinal fluid. No evidence was thus found of direct cerebral or meningeal involvement by the influenza virus. One hundred twenty-seven patients were admitted to hospital with severe laryngeal obstruction, 93 of them being children, aged 9 years or less. Influenza in young children may well predispose to secondary bacterial laryngotracheobronchitis; it can accelerate the obstruction of the airways, for they are small and likely to be impaired by the inflammation and edema which are produced by a pathogen with a predilection for respiratory epithelium and lymphoid tissue. The remaining 376 patients were admitted with pneumonia. Although younger patients predominated in this group, bacterial complications were proportionately more frequent among those over 40 years of age.

It was considered that the over-all isolation rate of pathogens from all the patients of this study provided a useful practical index of the causative agents as a basis for the initial treatment of these patients. It was apparent that the commonest pathogenic agent was Diplococcus pneumoniae, and this was confirmed by the clinical details, by x-ray appearances, and even by postmortem findings which showed it to be most commonly involved in death. Streptococcus, group A, appeared to be the next important causative agent, and Staphylococcus organisms were involved to a minor extent. Penicillin was used alone in the treatment of 82 patients who were admitted at an early stage of the disease. Tetracycline was combined with penicillin in the treatment of 201 patients in whom a broader antibiotic spectrum seemed desirable. According to subsequent bacteriological findings, combinations of penicillin, streptomycin, erythromycin, and Chloromycetin were used in those patients in whom it was considered that delay in the selection of the appropriate antibiotic would result in death. Adult patients with severe pneumonia were given 2 million units of penicillin every 2 hours; it was apparent that these large doses caused more rapid subsidence of fever and toxemia than did the administration of 1 million units every 6 hours.

Thirty-eight deaths occurred among the 672 patients. Most patients died as a result of associated diseases, such as congestive cardiac failure, cerebrovascular accidents, nephrosclerosis, emphysema, and myocarditis. Twelve of the 38 patients died of severe pneumonia. These data suggest that the influenza virus (Asian, type A) infection caused death occasionally in the absence of associated bacterial infection, while the severity of the secondary pneumonia suggested that without antibiotics, and particularly without penicillin, the mortality rate would have been even higher.

Hyperventilation Syndrome. J. Calvo Melendro and P. Sánchez-Malo Calvo. Rev. clín. españ. 69:205-210 (May 31) 1958 (In Spanish) [Madrid].

The syndrome of spontaneous (or idiopathic) pulmonary hyperventilation is of psychic origin. It is mainly due to emotions and linked to anxiety. It can be either acute or chronic. The predominant symptom is hyperpnea, which appears in association with dizziness, a feeling of emptiness of the head, cloudy state of the mind or complete loss of consciousness, certain sensorial and digestive signs, tachycardia, and precordial pain. In the course of the attack the arterial blood pressure falls; the electrocardiogram shows extrasystoles and abnormalities of the S-T segment and of the T wave, signifying a diminished output of the left ventricle. The electroencephalographic tracings are also changed. A diagnosis is made by the results of the pathognomonic test, which consists of the induction of provoked hyperpnea. The test is made by having the patient breathe deeply at a rate of 40 respirations a minute. In the presence of the syndrome a typical attack occurs within 15 or 30 seconds. In normal persons the test gives negative results even after 3 minutes. The contratest consists in making the patient breathe into a paper bag during an attack, thus compelling him to rebreathe his own expelled air. By these means the attack is aborted, and the act of breathing becomes normal within 15 or 20 respirations. The syndrome is frequent in women and rare in men.

The authors report 6 cases of hyperventilation syndrome in women, between the ages of 27 and 37 years. In all the patients the test of provoked hyperpnea and the contratest gave positive results. Emotions, excessive physical work, or mental anxiety were the eliciting factors of the attacks, which were repeated at very long and irregular intervals of time. In all the patients, also, the attacks lasted for a period that varied between 1 hour and 24 hours, during which more or less subdued hyperpnea continued. The hyperpnea stopped only if the attack ended, if the patient became unconscious, or if the contratest was carried out. The authors believe that the syndrome is caused by associated circulatory disturbances and disturbances of the centers of respiration. The main circulatory disorders involved in the development of the syndrome are an increased reflux of venous blood to the heart and a diminished arterial blood pressure.

Five-Year Follow-Up Study of Patients with Bleeding Duodenal Ulcer with and without Surgery. R. M. Donaldson, J. Handy and S. Papper. New England J. Med. 259:201-207 (July 31) 1958 [Boston].

Of the 1,149 clinical records of patients admitted to the Cushing and Boston Veterans Administration hospitals with conditions classified as "duodenal ulcer with hemorrhage," "gastrointestinal hemorrhage" without other symptoms, and "duodenal ulcer," 142 were selected for study, as they presented indubitable evidence of gastrointestinal bleeding and duodenal ulceration. Each of the patients had had one or more of the following: black stools (positive guaiac test), hematemesis, bloody gastric aspirate (positive guaiac test), and roentgenographic demonstration of a deformed duodenum or a definite ulcer. For purposes of study the patients were divided into 2 groups. The first group consisted of 100 patients who were first seen during their initial episode of gastrointestinal bleeding; the second group consisted of 36 patients who gave a history of one or more previous gastrointestinal hemorrhages. Before their present admissions, 71 patients had received transfusions of whole blood, and in 61 cases a diagnosis of duodenal ulcer had been made by x-ray examination; 22 patients, however, had not experienced abdominal pain or any other symptoms referable to the gastrointestinal tract. Roentgenographic confirmation of duodenal ulcer was accomplished in 127 patients, duodenal-bulb crater in 73, deformed duodenal bulb in 46, and postbulbar ulcer in 8.

Of the 100 patients in the first group, 38 suffered hemorrhage within 5 years of the initial episode, 10 of the patients bleeding on more than one occasion. Of the 13 patients operated on during the initial episode, bleeding was the major indication for surgery in 11, and associated pyloric obstruction in 2. An additional 25 patients were subjected to subtotal gastrectomy sometime during the 5-year period. Eleven of the 100 patients died within 5 years of the initial bleeding episode, 8 deaths being directly attributable to uncontrolled hemorrhage. Six of the deaths occurred during the initial hemorrhage, and 2 were due to proved gastrojejunal marginal ulcers developing 5 days and 2 months, respectively, after gastrectomy. In the first group there were 37 survivors at the end of 5 years who had had neither gastrectomy nor recurrent hemorrhage, a number which was reduced to 32 almost 2 years later. Of the 36 patients in the second group, 15 had further bleeding episodes within 5 years of the initial episode. There were no deaths in this group in the follow-up period, and at the end of this period 10 patients still had had neither gastrectomy nor recurrent hemorrhage. Recurrent bleeding within a 5-year period occurred in approximately 40% of the patients not operated on. There was a significant recurrence of bleeding after subtotal gastrectomy, 10 of 48 patients operated on experiencing hemorrhage within 5 years of operation.

SURGERY

Mitral Commissurotomy: Fifty Consecutive Cases with No Operative Mortality. A. M. Sabety and H. M. Ewing. J. M. Soc. New Jersey 55:418-421 (Aug.) 1958 [Trenton].

The authors report on their experience in the performance of 50 consecutive mitral commissurotomies without a single operative death. The present-day success of the surgical procedure is attributed to a better understanding of the abnormal physiology of mitral valvular stenosis and its alteration toward normal by surgery and to the tremendous strides that have been made in the selection of patients, operative technique, preoperative and postoperative care, and anesthetization. For purposes of classifying patients as to need for commissurotomy, those in this series have been divided into 4 groups: (1) patients who were asymptomatic, 0; (2) patients whose main symptom was dyspnea, 20; (3) patients with pulmonary hypertension, 26; and (4) patients with chronic right-heart failure, 4. An appreciable amount of calcification was found in 9 patients; no calcification was found in 19 patients; a regurgitant jet was noted in 13 patients; and 36 patients were operated on during chronic atrial fibrillation. The operative technique was essentially that which has become routine procedure in mitral commissurotomy; it emphasizes meticulous attention to every detail in opening the stenosed valve to its fullest extent and separating the chordae tendineae if they are found to be fused.

Failure and Replacement of Abdominal Aortic Grafts. M. R. Gaspar. Am. J. Surg. 96:202-212 (Aug.) 1958 [New York].

The author reports on 5 men, between the ages of 55 and 75 years, 4 of them with aneurysm of the abdominal aorta and 1 with thrombotic occlusion of the abdominal aorta, in whom grafts were used to bridge the defects resulting from the surgical removal of portions of the aorta. Nylon grafts were used originally in 2 patients and freeze-dried homografts in 3. Failure of the original aortic grafts occurred in all 5 patients. Thrombosis was the pathological process in the 2 patients with nylon grafts and in 1 patient with homograft. Failure occurred over a wide span of time, varying from the time of operation to 14 months after operation. Residual arteriosclerosis was the cause of failure of the 2 nylon grafts and 1 homograft. Obviously all of an aneurysm should be resected. Residual arteriosclerosis is more easily overlooked but must be removed or bypassed because it fosters occlusion of the graft. A poorly fashioned cloth synthetic graft was instrumental in the failure of the graft in 1 patient, thus showing that imperfect fashioning of grafts may be another cause of failure. Imperfect anastomoses also contributed to thrombosis within grafts. Defective freeze-dried homografts were the cause of failure in 2 of the 5 patients; in one patient the homograft ruptured at operation and in the other on the 4th postoperative day. Freeze-dried homografts appear to be unreliable unless some more satisfactory method of preparation is found. Four other ruptures of grafts were observed by the author, 2 in patients in whom freeze-dried human aortic grafts were used and 2 in cases of freeze-dried dog homografts. Synthetic grafts have not shown a tendency to rupture.

When abdominal aortic grafts fail, the entire grafts should be replaced. Bifurcation homografts were used for replacement in 2 of the 5 patients in whom the original grafts had failed, and thoracic aortic homografts were used for replacement in 3. Thoracic aortic homografts provide a larger diameter than bifurcation grafts and can be fitted more easily at the proximal end of the anastomosis. The replacement was successful in 4 of the 5 patients. Although this series is small, these results suggest that an attempt should be made to replace abdominal aortic grafts which fail. Additional years of observation will show which material is to be considered the best graft material for arterial substitutes.

The Outlook of Vascular Surgery Upon the Aged. C. R. Hitchcock and T. O. Murphy. Journal-Lancet 78:329-335 (Aug.) 1958 [Minneapolis].

Of 260 patients with vascular disease operated on at the University of Minnesota Hospitals and the Minneapolis General Hospital up to Sept. 1, 1957, 250 (96%) were 55 years of age or older. There were 150 patients with occlusive arterial disease; of these, 107 (71%) were between the ages of 60 and 75 years, and 29 (18%) were between the ages of 75 and 90 years. One hundred ten patients were operated on for arterial aneurysm; 74 (67%) of these were between the ages of 60 and 75 years, and 25 (22.7%) were over 75 years of age. In 83 (76%) of the 110 patients operated on for correction of a major arterial aneurysm, the procedure was successful. In the 18 patients operated on for ruptured aneurysm, 14 deaths occurred, and successful repair was done in only 4 (29%). Of the 92 patients operated on electively for aneurysms, only 10 died and the operation was successful in 80 (87%). These data emphasize the significant difference in the success rate of resection of aortic aneurysms in the elective stage as compared with the ruptured stage. Of the 150 patients who were operated on for segmental occlusive arterial disease and in whom bypass shunt grafts were used, the operation was successful in 16 (82%) of 21 patients with aorta-femoral bypass shunts, in 58 (79%) of 74 patients with femoral-popliteal bypass shunts, and in 2 patients with popliteal bypass shunts. The bypass type of arterial reconstitution is easier to accomplish technically than an in-line graft establishing direct continuity of the blood flow, since the arteries involved in the extremities are usually relatively normal, and end-to-side anastomoses are done with ease. The important small collateral arteries are not damaged by the bypass shunt technique; in the event of a subsequent thrombosis of the bypass shunt graft, the original vascular supply to the extremity is not significantly damaged, and the extremity, therefore, is not jeopardized.

These findings emphasize the tolerance of the elderly patient toward extensive vascular surgery. With advanced methods of anesthesia and prevention of hypotension during and after the surgical intervention, the results appear to be excellent. Arterial wounds and skin incisions in such patients have healed rapidly, and usually hospitalization has not been required longer than 14 to 18 days. The current surgical approach to serious vascular disease, a palliative one in the over-all problem of the treatment of arteriosclerosis, has a significant part to play in the attempt to prolong the life of patients in a manner permitting maximum usefulness of all their faculties.

Repair of Injury to the Common Bile Duct: Results in 69 Cases. G. L. Hoffman and G. Crile Jr. Cleveland Clin. Quart. 25:126-132 (July) 1958 [Cleveland].

Between 1950 and 1955, 89 operations for injured bile duct were performed at the Cleveland Clinic Hospital, of which 69 (performed on 58 patients) were classed as reparative. Of the 69 reconstructive procedures, 21 were hepaticoduodenostomies; 19 were simple dilatations with insertion of a T-tube; 12 were end-to-end anastomoses; 7 were hepaticojejunostomies; 5 were Roux-Y procedures; and 5 employed either a Vitallium-tube prosthesis, a skin grafting, or the Grindlay procedure. The best results were obtained in the first group (hepaticoduodenostomy), in which 18 patients were classified as having obtained good results—feeling well with no chills, fever, or jaundice. Two of the 3 patients in the first group, in whom operative results were not good and who had intermittent symptoms of cholangitis without jaundice, subsequently underwent gastric resection (Billroth 2) to exclude the biliary tract from the direct alimentary flow. The remaining procedures produced satisfactory results in less than 60% of the cases. The simplest approach to the damaged bile duct is through a subcostal incision, dissecting the undersurface of the liver from right to left. Fine chromic catgut is the suture material of choice. The most acceptable type of internal splint is the standard T-tube which, whenever possible, should be brought out through a separate opening and not through the anastomotic line, as is done when the stump of the proximal part of the duct is short.

Clinical Experiences with the Surgical Treatment of Acquired Aortic Vascular Disease. O. Gwathmey, H. C. Pierpont and B. Blades. Surg. Gynec. & Obst. 107:205-213 (Aug.) 1958 [Chicago].

A series of 53 patients with a variety of aortic vascular lesions treated during the past 4 years is reviewed in an attempt to correlate the authors' earlier impressions concerning the restoration of the aorta with more recent concepts. A total of 14 aneurysms involved all or part of the aortic arch. Syphilis was the etiological agent in 6, atherosclerosis in 3, and trauma in 3, the agent being undetermined in 1. The following adjunct techniques were used: hypothermia, staged segmental occlusion, and extracorporeal circulation. Three of the 14 were classified as emergency cases. Homologous freeze-dried grafts were used in 8 cases, while 2 cases required only aneurysmorrhaphy; 3 patients died prior to the grafting stage, and 1 patient was considered inoperable. There were no late complications in this group. Four patients were discharged as improved and are at present alive and well at 45, 44, and 30 months and 2 weeks after the operation. There were 3 delayed complications, and 7 cases were classified as immediate complications. There were 3 cases of aneurysm of the descending thoracic aorta—2 fusiform and 1 saccular lesions. A homologous and Vinyon "N" graft was used in 1 case, and Vinyon "N" and Orlon grafts were implanted in the other 2 cases. Hypothermia was used as an adjunct technique in 2 cases, and the aorta was cross-clamped under normothermic conditions in the other case. There were 2 late complications in this group and 1 immediate complication.

Thirty-seven patients with acquired lesions of the abdominal aorta were operated on. Thirty-two of these lesions were true aneurysms, all of them being basically fusiform in type but having saccular components superimposed. The etiological factor prevailing throughout the entire group was atherosclerosis. Thirty-five patients had resection of the diseased aortic segment with grafting. The only adjunct technique was hypothermia, which was used in 1 case only. Five types of grafts were used —homologous, Dacron, nylon, Orlon, and nylon crimp. Approximately 86% of the 35 abdominal lesions were aneurysms, the remaining 14% being due to thrombo-occlusive disease. In the elective group of 16 aneurysms there were only 3 complications (1 immediate, 1 delayed, and 1 late), in contradistinction to the 14 complications (4 immediate, 9 delayed, and 1 late) in the emergency group of 16 cases. In the 5 cases of thrombo-occlusive disease there were 3 immediate complications and 1 delayed complication. Thrombosis occurred in all 3 patients of the immediate group who underwent reexploration with reestablishment of circulation and required still a third procedure. Thrombosis as a complication in abdominal grafts occurred more frequently in thrombo-occlusive disease than in aneurysmal lesions.

Multiple Epiphysial Dysplasia. H. Barrie, C. Carter and J. Sutcliffe. Brit. M. J. 2:133-137 (July 19) 1958 [London].

Fairbank defined multiple epiphysial dysplasia as "a rare developmental error characterized by mottling or irregularity in density and outline of several of the developing epiphyses, dwarfism, and stubby digits." Symptoms invariably begin in childhood, the youngest recorded case being that of a 19-month-old infant. In the present series the ages ranged from 2 to 71 years. The most prominent symptoms are joint pain and stiffness with a variable degree of disability. Since the lesions are multiple rather than generalized, symptoms predominate in specific joints, the hip and knee joints being the most commonly affected as they are the most liable to weight-bearing strain. The distribution of symptomatically involved joints does not necessarily parallel the roentgenographic distribution, which is more often than not severest in the epiphyses of the wrist, hands, and ankles. The degree of disability varies from slight discomfort to marked impairment of function, and although the changes in the epiphyses are permanent, the symptoms are characteristically transient and fluctuating. Osteoarthritis is an inevitable complication, and severe hip trouble may cause difficulty in natural childbirth. Similar symptoms and signs as well as roentgenographic features prevail in affected members of the same family. The familial pattern suggests that dominant genes are responsible for all examples of the disorder, although more than one mutation would seem to be necessary to explain the differing degrees of severity in different families. Patients who receive physical therapy early in life are afforded considerable relief at the time and subsequently develop less disability.

A New Therapeutic Concept of the Exstrophied Bladder. C. S. Snyder. Plast. & Reconstruct. Surg. 22:1-10 (July) 1958 [Baltimore].

The author reports on 2 boys, aged 1 year and 6 months, respectively, who were operated on for exstrophy of the urinary bladder. The intestinal tract was prepared with a combined sulfo-neomycin medication 3 days before the surgical intervention, and enemas were given 2 days before the operation. With the aid of general endotracheal anesthesia, the abdomen, perineum, buttocks, and thighs were surgically cleansed and aseptically draped. A catheter was placed in each ureter. The bladder was dissected from the abdominal wall, isolating the ureters and preserving the vesical blood vessels. The rectum was elevated from the posterior part of the pelvic wall, and a site of transection was selected 2 in. above the anal outlet. A fenestration was made in the posterior part of the bladder wall between the ureters, and the distal end of the rectal segment was coapted to it with 2 layers of sutures. The ureteral catheters were brought through the anal orifice by way of the new urinary rectal receptacle. An incision was made posterior to the anal outlet but within the external and internal anal sphincters. The proximal end of the rectal segment was pulled through the levator ani sling and within both anal sphincters. It was sutured to its recipient site, leaving a redundancy of intestine present externally. The bladder was closed over an indwelling catheter which was brought through the abdominal wall. The abdomen was closed in layers without tension. Each patient lost approximately 150 cc. of blood, which was replaced during the operative procedure. On the second postoperative day the ureteral catheters were removed, and the next day the remaining indwelling catheter was extracted. Both patients had uneventful recoveries.

The fact that due to this operation the urinary stream is completely separate from the fecal discharge is of definite advantage, as it eliminates ascending renal infection which has been the most common complication of operative procedures previously in use. There is no problem of ureteral obstruction at a site of anastomosis, because the ureters are left intact to empty their contents as they should into the bladder. The patients of this report have been followed for 1 year postoperatively, and no complications have occurred to give reason that these 2 boys operated on for bladder exstrophies should not enjoy a normal life expectancy. Two other patients have been operated on since the author's paper was submitted for publication, and both are doing well. Follow-up intravenous pyelograms have illustrated normal functioning genitourinary tracts.

Operations for Extreme Mitral Stenosis in Patients over 45 Years of Age: Preoperative and Postoperative Study of 35 Cases. P. Soulié, F. Joly, P.-E. Gareau and P. Corone. Arch. mal. cœur 51:616-625 (July) 1958 (In French) [Paris].

The authors report on 26 women and 9 men, between the ages of 45 and 54 years, with extreme mitral stenosis in that the mitral orifice was reduced to a cross sectional area 1 sq. cm. or less. Although all the patients had had moderate dyspnea on effort for a prolonged period varying from 2 to 20 years, their activity was hardly impaired until the clinical and hemodynamic symptoms of mitral narrowing became much more severe after the age of 40. Pulmonary edema on effort or subacute edematous attacks were observed in 31 patients. Hemoptysis occurred in 11 patients, and bloody sputum was observed in 6. Pulmonary embolism occurred in 7 patients and other systemic embolic attacks in 5. Complete arrythmia was noted in 20 patients. Signs of overload on the right ventricle were revealed by the electrocardiograms obtained from 31 patients. The volume of the heart was increased in 23 patients, and the pulmonary arteries were dilated in all the patients. The pressure in the pulmonary capillaries varied between 20 and 30 mm. Hg. The pressure in the pulmonary arteries also was increased; the systolic pressure varied between 80 and 140 mm. Hg in 12 patients, and the average pressure was above 50 mm. Hg. Commissurotomy was performed with the knife on 24 patients and by digital fracture on 11. Three patients died, 2 of ventricular fibrillation in the course of surgical intervention and 1 of cardiac decompensation 3 months after the operation.

The 32 patients who survived the operation were followed for 9 to 24 months. Functional disturbances subsided in varying degree in almost all of them. Pulmonary edema disappeared and hemoptysis did not occur. Dyspnea on effort was completely absent in 13 patients, nearly completely in 10, and partly in 9. Postoperative electrocardiographic changes were studied in 27 patients. Four of these had not shown preoperatively signs of overload on the right ventricle, and their postoperative electrocardiograms were not changed. Of the remaining 23 patients, the condition of 19 was improved in that there were less signs of overload on the right ventricle, and only 4 were not improved. Most improved were those in whom the preoperative overload on the right ventricle had been most pronounced. Of 15 patients who underwent catheterization postoperatively, the pressure in the pulmonary capillaries was reduced by 12 to 20 mm. Hg in 10 and by 7 to 10 mm. Hg in 3; the pressure in the pulmonary arteries also was reduced in all these patients, and it was restored to normal in 3. Two patients did not show hemodynamic improvement because of a systolic reflux which had become more pronounced.

These observations show that the results of commissurotomy, performed on patients in the 5th and 6th decades of life when moderate mitral narrowing has become more severe, remain satisfactory. It might be that the operative risk is somewhat greater and that complete regression of the hemodynamic and electrocardiographic symptoms may occur less frequently than in younger patients, but the differences are not significant. Such patients should, therefore, not be denied surgical intervention because of their advanced age alone.

NEUROLOGY & PSYCHIATRY

Pelizaeus-Merzbacher Disease: A Clinical Study. H. R. Tyler. A. M. A. Arch. Neurol. & Psychiat. 80:162-169 (Aug.) 1958 [Chicago].

The author reports the cases of 3 Negro boys, between the ages of 9 and 16 years, with a slowly progressive hereditary form of cerebral diplegia characterized by early development of nystagmus, ataxia, and spasticity. The 3 patients were brothers and belonged to a large family in which 27 members in 7 generations were affected with this disease in a fairly stereotyped and predictable manner. The disease was always transmitted through an unaffected female, and the affected male never reproduced. No female member with the disease was known. If the male was not affected, then his children, including the daughters, did not reproduce the disease. About 50% of the females had affected children, but the cases of the 3 boys were the only definitely known ones. Other members of the family called these affected persons "head nodders" and "eye waggers." The condition was usually observed about 8 to 10 days after birth, and sometimes as late as 3 months. The parents noted that the eyes were constantly moving and that the head was moving in a repetitive side-to-side tremor. The children were hypotonic and rarely learned to sit or stand. Placing reactions were usually lost by 18 months of age. Some of the patients could propel themselves by a peculiar writhing, snake-like motion of the body, with head held extended. This was the only demonstration of a righting reflex noted. By the age of 3 to 6 years, kyphoscoliosis, spasticity in the lower extremities, athetosis, intention tremor, and slight regression in the mental state were noted. The upper extremities became slightly spastic by the age of 10 to 12 years. Thin arms and legs were noted in some members of the family. The rate of progression of the disease seemed to become slower and slower with each year until it appeared almost as though, in some of the older affected persons, it occasionally became stationary. Most of the patients died of intercurrent infections in early years. One lived to 51 years of age.

The symptoms of the patients in this study were those of diffuse sclerosis of the subcortical white matter, which were first described in 14 members of a family by Pelizaeus and Merzbacher, after whom the disease has been named. The only points of difference between the 2 families with this rare hereditary disease were that the pattern of onset of symptoms appeared more rigid in Tyler's patients, that none of the female members were affected in contrast to 2 females in the original family, and that remissions were less obvious in the original family. The early development of nystagmus and other brain-stem signs distinguishes the illness from the familial forms of Schilder's disease (progressive subcortical encephalopathy) and metachromatic leukoencephalopathy.

Lobotomy: A Fifteen-Year Study. A. McCausland and D. M. Wickware. Canad. M. A. J. 79:168-170 (Aug. 1) 1958 [Toronto].

Two hundred patients who had been subjected to a standard bilateral lobotomy have been followed for 3 to 15 years. The age range of the patients, 146 females and 54 males, was from 18 to 77 years, the greater number of patients falling in the 30-to-59-year age group. The average length of time from onset of illness to operation was 143.6 months, while the total hospital stay prior to operation averaged 47 months. The mortality rate to date for the entire series of 300 cases has been 0.3%. Schizophrenia accounted for a greater proportion of failure and a correspondingly lesser degree of improvement than did manic-depressive psychosis. The results for involutional melancholia and schizoaffective psychosis cannot be accurately assessed because of the small number of patients in these groups. Classification by age group indicates that results were better for patients in the 40-to-59-year age group and less favorable for the 20-to-39 and 60-to-70-and-over age groups. The latter results would seem to reflect the preponderance of schizophrenic disorders in the 20-to-39-year age group.

Anorexia Nervosa: A Somatic Disorder. E. Williams. Brit. M. J. 2:190-195 (July 26) 1958 [London].

The author reports on 53 female patients, between the ages of 12 and 40 years, with anorexia nervosa who were admitted to the London Hospital; 49 were admitted between 1897 and 1953, and 4 between 1953 and 1957. Marked weight loss and amenorrhea were present in all. Despite extensive investigation, none showed evidence of primary organic disease. The patients were hospitalized for periods ranging from 7 to 130 days, except one patient who was comatose on admission and who died the next day. Few patients were confined to bed, and for most of them no special diets were prescribed. Renourishment of 7 patients was accomplished by feeding with the stomach tube, and in these patients the immediate results were so good that on discharge each had gained, on the average, 22 lb. (10 kg.). Of the 46 patients who were not treated with intubation, 7 gained more than 14 lb. (6.4 kg.) in weight while in the hospital, but the weight was restored to normal in only 5 of these. The other 39 patients in this group gained, on the average, only 9 lb. (4.1 kg.) per patient.

Seven of the 53 patients who were treated for anorexia nervosa were lost to follow-up. Of the 46 patients who were followed, 10 have died, 3 have not improved, 6 have improved, and 23 have completely recovered. It is still too early for an evaluation of the 4 patients who were admitted after 1953, but they have all been treated with intubation which is the most effective in-patient treatment. The deaths of 8 of the 10 patients who died resulted solely from malnutrition. Other patients who were just as severely undernourished recovered spontaneously after having been refractory for a varying number of years. They resumed eating of their own volition, mostly after their environment had deliberately or accidentally been changed.

Promising Results in Cryptococcal Meningitis. H. Rubin and M. L. Furcolow. Neurology 8:590-595 (Aug.) 1958 [Minneapolis].

The authors report on their experience in the treatment of 10 cases of cryptococcic meningitis with Amphotericin B. Cryptococcus neoformans was isolated from the spinal fluid of all the patients and from the skin lesions of 2 patients. The pathogenicity of all isolated strains was confirmed by the demonstration of capsule formation and growth of budding yeast forms at 37 C; 9 of the 10 isolated strains were also shown to be pathogenic for mice, with the development of hydrocephalus after cerebral inoculation. Amphotericin B was administered intravenously to all the patients in doses ranging from 50 to 100 mg. for a total dose of 1.4 to 3.7 Gm. Eight of the 10 patients are alive at follow-ups ranging from 2 to 14 months. In the 2 fatal cases both patients were comatose and moribund before treatment and never regained consciousness. Two of the surviving patients are pursuing normal activities and have normal spinal fluids which have remained sterile upon repeated culture; 3 patients have shown clinical improvement with either normal or improved spinal fluid indexes; 1 patient has remained stable in spite of previous long-standing central nervous system disease; and 2 patients have suffered relapses. Toxic side-reactions to Amphotericin B have been minimal, although therapy was suspended in one patient because of symptoms ascribed to liver toxicity. Chemical phlebitis occurred. Fever, chills, and nausea sometimes accompanied the initial intravenous infusion but were diminished or avoided by premedication. The most promising finding, upon evaluation of therapy, is the consistent sterility of the spinal fluids in 7 of the 8 surviving patients.

Intracranial Hemorrhage in Cerebral Arteriovenous Anomalies. M. W. Wood and H. J. Svien. A. M. A. Arch. Neurol. & Psychiat. 80:170-172 (Aug.) 1958 [Chicago].

Of 51 patients with cerebral arteriovenous anomalies which were revealed either at surgical intervention or by angiography at the Mayo Clinic, 16 patients, 8 male and 8 female, between the ages of 6 and 60 years, had 20 attacks of subarachnoid hemorrhage. The average age at the time of hemorrhage was 31 years. Three of the 16 patients had more than 1 attack of bleeding, 1 having 3 attacks and 2 having 2 attacks each. In all 20 episodes the patients had severe headache at the onset, and nausea and vomiting appeared early in about two-thirds. The patients were unconscious in 8 of the 20 attacks of hemorrhages, and in 2 of the 8 for less than 1 day. Recovery occurred in 6 of the 8 instances, but 2 patients died during the hemorrhage. Seven patients had no definitive surgical treatment for their lesions. The 2 deaths from subarachnoid bleeding which occurred in this group gave a mortality rate of 12.5% for the entire series, which was about the same as that reported by other workers. No bleeding recurred for 7 to 16 years in the other 5 patients who were not surgically treated for their lesions. Of these 5 patients, 3 have no residual paralytic or speech defects, but 2 have some degree of residual hemiparesis. Nine of the 16 patients were treated surgically. No deaths from bleeding occurred in this group, but 4 of these patients have had attacks of subarachnoid bleeding since operation.

Although this group of 16 patients with intracranial hemorrhage is small, certain characteristics of bleeding from arteriovenous anomalies can be deduced as follows. The bleeding from a cerebral arteriovenous anomaly is not nearly as fulminating as that from a cerebral aneurysm; bleeding from an arteriovenous anomaly is not nearly as likely to be fatal as that resulting from a ruptured cerebral aneurysm. Residual neurological deficit is neither frequent nor often profound.

It is generally conceded that subarachnoid bleeding from a cerebral aneurysm is an indication for surgical treatment in patients who survive the initial attack and in whom such factors as age are not contraindications. Subarachnoid bleeding from an arteriovenous anomaly does not have the same ominous connotation as that resulting from a cerebral aneurysm. Hence, one must be cautious in considering subarachnoid bleeding from an arteriovenous anomaly as an indication for surgical removal of the lesion. Another reason for caution is the appreciable operative mortality rate. Furthermore, even though total excision is thought to have been accomplished at operation, long-term follow-up observations may prove this to be untrue, leaving the same set-up for bleeding as before. It should be kept in mind that the residual neurological deficit in most of the surgically treated patients is bound to be appreciable because of the frequent location of the anomaly in the vicinity of the Sylvian and Rolandic fissures.

GYNECOLOGY & OBSTETRICS

Progesterone-Induced Withdrawal Bleeding as a **Simple Physiologic Test for Pregnancy.** G. E. Hayden. Am. J. Obst. & Gynec. 76:271-278 (Aug.) 1958 [St. Louis].

The author presents a study on the differentiation of early pregnancy from secondary amenorrhea of short duration. The use of progesterone as a diagnostic and a therapeutic agent in the management of amenorrhea has been evaluated, and the application of progesterone-induced withdrawal bleeding as a diagnostic test for pregnancy has been employed in 102 women whose ages ranged from 18 to 35 years. The patients were selected only on the basis of previously regular menstrual periods and the distinct possibility that a conception had occurred. They were amenorrheic for 35 to 70 days. Forty-four patients were given anhydrohydroxyprogesterone orally in a dose ranging from 200 to 400 mg. per day for 4 or 5 days. In 43 patients progesterone, U.S.P., was administered vaginally in a dose ranging from 75 to 250 mg. per day for 4 or 5 days, and in 15 patients 17-alpha-hydroxyprogesterone caproate was injected intramuscularly in a dose ranging from 125 to 500 mg. per day for 2 to 5 days. Sixty-four patients failed to respond, and pregnancy was confirmed in each instance. All the pregnancies continued uneventfully, and normal-term infants resulted. In 38 patients withdrawal bleeding occurred. In 23 (85%) of 27 patients who had received progesterone preparations either by mouth or vaginally, the onset of withdrawal bleeding occurred between the 3rd and the 7th day from the day of cessation of medication. In 8 (72%) of 11 patients to whom the progesterone preparation had been administered intramuscularly, the onset of withdrawal bleeding occurred between the 8th and the 14th day; in 1 patient the onset occurred even on the 16th day. Thus, the oral or vaginal mode of administration may be preferred to the intramuscular route. The amount and duration of bleeding could not be correlated with the mode of administration or amount. No alteration in the course of pregnancy was noted with either standard or excessively large dosage. Of 36 patients on whom follow-up examinations were carried out, 26 (72%) returned to normal menstrual cycles, and no further evaluation or therapy was indicated or needed. Two patients were lost to follow-up. Thus, because of its diagnostic as well as its therapeutic value, progesterone may be used even more extensively in patients with the brief or functional type of amenorrhea.

Current Treatment of Carcinoma of the Cervix. H. L. Kottmeier. Am. J. Obst. & Gynec. 76:243-251 (August) 1958 [St. Louis].

According to Kottmeier, the intracavitary radium treatment for carcinoma of the cervix must be individualized. Thus, the radium application in a patient with a narrow vagina should be quite different from the application in a patient with a large vagina; the intrauterine application of radium is to a much greater extent responsible for the dosage in the paracervical tissue and in the pelvic nodes than is the vaginal application of radium, and the contrary is true as far as the paravaginal spread of the cancer is concerned. This applies to cases of endocervical carcinoma or to those with a paracervical spread of the neoplasm. The intrauterine dose of radium should be considerably increased in such cases and the vaginal dose decreased. Thus, in a case of endocervical carcinoma, stage 1, the application of radium should be quite different from that in a case of disk-shaped carcinoma in the part of the uterine cervix which protrudes into the vagina.

The current individualized technique was started in 1949 at the Radiumhemmet in Stockholm. The treatment time was determined in the individual case by a direct reading of the dosage in the posterior wall of the bladder and the anterior wall of the rectum. A small ionization chamber contained in a curved probe was inserted first in the bladder and then in the rectum to a depth of 14 cm. With the probe in the midline and with gentle pressure on the wall, it was slowly withdrawn, and the dosage rate at each centimeter of distance was recorded. With the high intensity used, the optimal dose in the bladder was about 5,500 gamma r and in the rectum 4,000 gamma r, provided that attention was given to the dosage in an area of 3 cm. or more. A higher dose would increase the risk of proctitis or bladder damage. Overradiation of normal tissue should be avoided. Fractionated irradiation was preferable.

In uncomplicated cases, the intracavitary application was divided into 2 treatments, with an interval of 3 weeks. In infected cases, it was expedient not to apply the intrauterine and vaginal doses of radium simultaneously. In cases of endocervical carcinoma, of spread of the cancer to the paracervical tissue, and of pelvic lymph node metastases, an increase in the intrauterine dose was desirable. This might be realized by an increase in the time the radium was left in place or by an increase in the amount of radioactive material applied. From 100 to 200 mg. of radium was inserted into the uterine cavity, depending on the length of the sound. The diameter of the applicator was increased in order to avoid necrosis in the uterine wall. The application was controlled by the probe inserted into the rectum. It was preferable not to exceed a dosage of 2,500 gamma r in 24 hours to the anterior wall of the rectum and, furthermore, not to give external radiotherapy immediately after such an application. Additional roentgentherapy was given to the pelvic wall of every patient from 2 anterior and 2 posterior portals. The dosage ranged from 2,000 to 2,400 r in 24 to 32 days, although sometimes it was desirable to increase the dose to the pelvic wall. Prior to this additional therapy, however, a urovenogram was required for the purpose of obtaining information on pelvic anatomy. The marked improvement in the results obtained with this type of therapy supports the importance of individualization.

One thousand eighty-one patients were treated in Stockholm during the 3 years from 1949 to 1951. The oldest patient was 96 years of age, with a stage 1 carcinoma. Fifty-three patients were 30 years of age or younger. Palliative radiotherapy, i. e., one radium treatment or a few x-ray treatments, was given in 7.4% of the cases. Radical hysterectomy was carried out later in 43 cases of persistent or recurrent carcinoma, and fulguration was performed in 83 cases. The 5-year apparent recovery rate was 89.0% in stage 1, 64.4% in stage 2a, 45.2% in stage 2b, 33.5% in stage 3, and 7.8% in stage 4. Since 1949 a case has been allotted to stage 4 only if invasion of the bladder or rectum was proved histologically or distant metastases were present. Thus, the average 5-year cure rate was 51.1%, as compared with an average 5-year cure rate of 42.3% among patients treated between 1936 and 1945 and of 42.5% among those treated between 1946 and 1948.

The Importance of Highly Purified Bacterial Lipopolysaccharides for the Therapy of Inflammatory Diseases of the Adnexa. H. Fricke, V. Probst and G. Schumacher. Schweiz. med. Wchnschr. 88:691-698 (July 12) 1958 (In German) [Basel, Switzerland].

Whereas in the past vaccine preparations were chiefly used in nonspecific fever therapy, the authors are concerned with the use of the highly purified lipopolysaccharide Pyrexal that is extracted from Salmonella abortus equi. The preparation is free from protein and nucleic acid and consists largely (60%) of sugars and (40%) of lipids (lipid A). An intravenous injection of 0.1 to 0.2 mcg. of

Pyrexal produces a temperature increase of from 1 to 2 degrees (C). The temperature elevation appears after a latent period of 1 or 2 hours and subsides again from 6 to 8 hours after the injection. The pyrogenic threshold dose is the intravenous injection of 0.002 to 0.003 mcg. per kilogram of body weight. The fever-inducing effect gradually decreases after repeated injections, and so it becomes necessary to increase the dose gradually to insure the same effect. Pyrexal induces leukocytosis, activates fibrinolysis, and increases the serum properdin twofold to threefold.

The authors demonstrate on the basis of clinical studies that the intravenous administration of bacterial lipopolysaccharides produces excellent therapeutic results in the treatment of adnexitis. A comparison of the results obtained in 50 patients who were treated with the lipopolysaccharide Pyrexal with those obtained in 385 patients who were treated with the customary conservative methods demonstrated not only that the over-all results in acute and chronic cases were better with the intravenous fever therapy but that, in contrast to experiences in earlier years, patients treated during the acute and the subacute stage have better chances of recovery. In view of the anatomic and topographic peculiarities of the involved adnexa (small organ—large peritoneal surface) with extensive fibrinous exudates, adequate treatment of the inflammatory masses seems to depend on increase in resistance, on stimulation of the properdin system, on activation of the reticuloendothelial, leukocytic, and anterior-pituitary/adrenocortical systems, and particularly on the stimulation of fibrinolytic processes. The uniform course of the reaction that can be expected regularly after the intravenous injection of highly purified bacterial lipopolysaccharides greatly facilitates their clinical use. Side-effects usually take the form of headaches that can be readily controlled by suitable drugs. The occurrence of painful reactions at the site of the inflammation may be employed for differentiating adnexitis from tumors of the adnexa.

Treatment of Functional Uterine Bleeding with 17-Alpha-Hydroxyprogesterone Caproate (Efficiency and Limitations of Therapy). H. Zorn. Geburtsh. u. Frauenh. 18:924-933 (July) 1958 (In German) [Stuttgart, Germany].

The author reports on 224 female patients with functional uterine bleeding who were treated with a mixture of estradiol benzoate, estradiol valerate, and 17-alpha-hydroxyprogesterone caproate given parenterally. One hundred thirteen patients were admitted to the gynecologic clinic of the City Hospital in Berlin-Friedrichshain, Germany, and the remaining 111 patients were treated ambulatorily. Thirty-five of the 224 patients were immature girls, 35 were mature women, and 154 were at the termination of their reproductive period. Sixty-two patients received 125 mg. of hydroxyprogesterone caproate and 10 mg. of estradiol benzoate, 60 patients received 250 mg. of hydroxyprogesterone caproate and 10 mg. of estradiol benzoate, 24 patients received 375 mg. of hydroxyprogesterone caproate and 10 mg. of estradiol benzoate, 58 patients received 250 mg. of hydroxyprogesterone caproate and 10 mg. of estradiol valerate, and 20 patients received 250 mg. of hydroxyprogesterone caproate, 10 mg. of estradiol benzoate, and 10 mg. of estradiol valerate. Independently of the duration of bleeding before treatment and independently of the dosage employed, primary hemostasis was obtained within 24 to 36 hours as a rule, and within 48 to 60 hours at the latest, in 209 women (93.3%). The treatment failed in 5 patients, and in 7 additional patients bleeding was arrested later with conservative measures. Three women were lost to follow-up and were also considered as failures. Definitive arrest of bleeding without withdrawal bleeding occurred in 4 women, between the ages of 41 and 51 years; it may be assumed that an exclusive estrogen effect was exerted on an almost exsanguinated mucosa in these 4 patients. Withdrawal bleeding occurred in 201 patients within 10 days, on the average, and its course was uneventful in 189 (84.3%). Further intervention was not required. The withdrawal hemorrhage lasted, on the average, for 8 days. Failure of the treatment nearly always indicated an organic endometrial disorder as the cause of the hemorrhage.

Thirty-five women with histologically proved organic disorders, such as polyps of the uterine cervix or the body of the uterus, endometritis, and inflammatory processes of the adnexa associated with bleeding, were given the same treatment as the patients with functional bleeding. Arrest of bleeding occurred for a short time in 18 patients and was followed by withdrawal bleeding in some of them; the latter often was severe and prolonged. Administration of large doses of 17-alpha-hydroxyprogesterone caproate not only delayed the onset of withdrawal bleeding by 4 to 6 days but also markedly reduced the blood loss. With combined administration of 17-alpha-hydroxyprogesterone caproate and long-acting estradiol valerate, there was a delay before the hemostatic effects became manifest, but withdrawal bleeding was shortened by 2 or 3 days. The delay in the hemostatic effect may be prevented by the combined administration of estradiol benzoate and estradiol valerate with 17-alpha-hydroxyprogesterone caproate. Although treatment with the estradiols and 17-alpha-hydroxyprogesterone caproate had beneficial effects in patients over 45 years of age, the author cautions against its routine use in these patients unless microscopic examination has excluded the possibility of carcinoma. Recurrent hemorrhages were observed in 5 (6.2%) of 89 patients who were followed up for more than 6 months after the treatment. Judged by this incidence of relapses, hormonal therapy does not appear to be inferior to surgical procedures in the treatment of functional uterine bleeding.

Prognosis in Acute Renal Insufficiency Originated After Delivery. J. H. Thaysen, S. Gjørup and O. Munck. Ugeskr. læger 120:899-905 (July 10) 1958 (In Danish) [Copenhagen].

The prognosis for patients with acute renal insufficiency depends partly on the nature of the basic disease and partly on the duration and degree of severity of the complicating uremia. Reports from dialysis centers in Denmark emphasize that the high lethality in patients with acute renal insufficiency is almost entirely to be ascribed to the basic disease which causes the renal insufficiency. The prognosis for uncomplicated renal insufficiency is relatively good, even with uremia of long standing. Report is given on 9 women with acute renal insufficiency post partum, admitted to date in the dialysis section of the medical division of the Rigshospital. The basic disorder was in most cases reversible. The prognosis in such cases depends almost wholly on the treatment of the uremia. One patient with bilateral renal cortical necrosis died; after 51 days of conservative and dialytic treatment no restitution of renal function had resulted. In several of the survivors the reduction of renal function was prolonged. Combined conservative and dialytic treatment has changed the prognosis for acute renal insufficiency. Further reduction of the mortality in patients with acute renal insufficiency must first of all depend on active treatment of the basic disease when it continues to dominate the picture and threatens life. Only hemodialysis affords the possibility of bringing the patients into such a condition that this treatment can be carried out. All patients with acute renal insufficiency, irrespective of the character of the basic disease, should be transferred to a dialysis section as soon as possible.

Listerosis in Mother and Child. O. Kranendonk. Nederl. tijdschr. geneesk. 102:1202-1206 (June 21) 1958 (In Dutch) [Amsterdam].

The first-born child of a woman, who had felt "grippy" some weeks before delivery, appeared healthy until the 4th day of life. Then the infant refused to drink, an exanthem was observed, and the head was bent backward. Spinal puncture yielded fluid containing some erythrocytes, and some slender, gram-positive rods were observed. Colonies of a bacterial organism grew in a culture of the spinal fluid. Intraperitoneal injection of the culture into mice resulted in death of the animals after from 1 to 4 days, and focal necroses were seen in the livers of the mice. The strain of the injected organism could be cultured from the livers and the heart-blood of the animals. The organism was identified as Listeria monocytogenes. Studies on the mother revealed that she harbored L. monocytogenes in the vagina 10 days and 3 weeks after delivery. The strain isolated from the mother was serologically identical with that cultured from the spinal fluid of the newborn infant. It is suspected that the mother was infected by a pet dog which some weeks before delivery had had fever and a stiff neck, although its sickness was not bacteriologically studied. Literature reports are cited to prove that more attention is being paid to L. monocytogenes as a pathogenic agent in man and in animals.

Staphylococcal Infection in Mothers and Infants: Maternal Breast Abscesses and Antecedent Neonatal Sepsis. J. A. Monro and N. P. Markham. Lancet 2:186-190 (July 26) 1958 [London].

Most epidemics and sporadic infections have been caused by antibiotic-resistant strains of staphylococci belonging to the phage-type 80/81, which are now firmly entrenched and widely distributed in New Zealand. Thirty-seven cases of maternal breast abscess developing in the weeks after childbirth and known to have followed confinement in maternity homes were investigated. Of the 37 patients, 31 required hospital admission for incision and drainage, and in 32 patients bacteriological investigations were carried out. Coagulase-positive staphylococci were obtained from 31 of the 32 patients investigated, 24 of the strains being identified as phage-type 80/81 and 21 exhibiting a characteristic antibiotic-sensitivity pattern. The time of onset in 23 of the 33 abscesses was between 2 and 4 weeks after confinement, although no relationship in time was discernible regarding the advent of or any change in lactation. A history of cracked nipples (14) in the mothers or infection (25) in the infant or both was forthcoming from 27 of 29 patients interrogated. Antibiotics given to 22 patients afforded them no relief, and in no case did antibiotics facilitate remission, once a mass was formed. Both breasts were affected in 5 patients, and 16 patients required incision on 2 or more occasions. While the strain of the organism from the abscess was isolated from the mother's nose on only 2 of 12 occasions, the "abscess strain" was carried by the infant in almost all the cases studied. This same strain was isolated from the breast milk in almost half of the patients examined. The incidence of staphylococcic skin lesions has been reduced from 11 to 6% since the introduction of new nursing techniques. No frank examples of umbilical sepsis were encountered. The proportion of nursing and other hospital staff personnel carrying coagulase-positive staphylococci varied between 22 and 48%, the proportion of penicillin-resistant carriers remaining at about 70%. Similar figures were obtained from the medical staff. The over-all maternal carrier rate of coagulase-positive staphylococci ranged from 30 to 36%; however, the incidence of penicillin-resistant strains among the mothers (35%) was half that among the nurses. No coagulase-positive staphylococci were isolated from the dust and air samples taken from the nurseries and theaters in one hospital, although in another older institution 9 of 43 specimens were positive, 2 being identified as phage-type 80/81. The authors conclude that a nursery may be "seeded" with staphylococci from a nasal carrier among the staff and that a nursery "reservoir" of staphylococci may persist by hand or air transfer from infant to infant.

The Indications for Conservative Therapy for Intraepithelial Carcinoma of the Uterine Cervix. J. S. Krieger and L. J. McCormack. Am. J. Obst. & Gynec. 76:312-320 (August) 1958 [St. Louis].

The authors report on clinical observations made between 1950 and 1957 at the Cleveland Clinic Hospital on 114 patients in whom the diagnosis of cervical carcinoma in situ had been established. The cervical smear was used for the clean, normal-appearing cervix, and the cervical smear and multiple biopsies were used for the abnormal cervix. Sixty-five of the 114 patients were first suspected of having carcinoma in situ from routine cervical smears; diagnosis was established in 28 patients by means of smear and biopsy; in 21 patients with a concomitant disease diagnosis of carcinoma in situ was made incidentally. Until late in 1951 the treatment for cervical intraepithelial carcinoma was total hysterectomy performed within 6 weeks after diagnosis by conization had been made. Since 1952 the treatment of choice, in the absence of other diseases that may require hysterectomy, has been radical conization. To assess the adequacy of the conization, it should be followed up by systematic cytological examination if the lesion is noninvasive in the conization specimen, if the cervix remains patent after conization, and if repeated smears remain negative. Hysterectomy is reserved for those patients in whom cervical smears remain positive after conization, the cervix closes and renders smears unreliable, or other major uterine disease is present. Radical conization was carried out in 65 of the 114 patients; in 30 conization followed by hysterectomy or trachelectomy was performed; in 10 hysterectomy was done after biopsy, and in 2 hysterectomy only was performed; 2 patients received radium therapy, and 5 were not treated after consultation. Of the 65 patients with radical conization, 4 were lost to follow-up, and 61 were followed for 6 months to 7 years; cervical smears have been negative repeatedly in all but 2 patients. Of the 30 patients who underwent hysterectomy or trachelectomy after the conization, 26 had no residual disease in the excised cervix, and 4 had evidence of persistent carcinoma in situ. The hysterectomy had been performed in 3 of the latter patients because of the evidence of unusually extensive disease in the conization specimen. These data suggest that hysterectomy is not a therapeutic necessity in treating cervical carcinoma in situ. Treatment can be individualized and is usually limited to radical conization with systematic cytological follow-up.

Occurrence and Significance of Free Tissue Fluid in the Female Mammary Gland. M. Ratzenhofer. Geburtsh. u. Frauenh. 18:893-906 (July) 1958 (In German) [Stuttgart, Germany].

Under physiological conditions, such as the menstrual cycle and particularly during pregnancy, the interlobular, collagenous, supportive tissue of the mammary gland contains microscopically demonstrable amounts of free interstitial fluid (tissue fluid) rich in protein. The amount of the fluid was found to be considerably increased to a macroscopically recognizable edema of the breast in women with painful swelling of the mammary glands, in those with mammary fibrosis, and in those with chronic fibrous mastopathy. Increased amounts of this interstitial fluid in the connective tissue were also observed in patients with cancer of the breast and associated fibrous mastopathy and particularly in women with obstruction of the lymph passages by cancerous growth. Chemical examination of the blood-free tissue fluid obtained from patients with such noninflammatory, benign or malignant, changes of the mammary gland revealed a surprisingly high protein content (on the average 4.5 to 5 Gm. per 100 cc.); the proportion of the protein fractions was about the same as that in the blood serum, but the albumin-globulin ratio was higher. The isoagglutinins and the electrolytes were the same as in the serum, although their concentration was slightly lower. These findings indicate that the tissue fluid originates from the blood serum.

The considerable accumulation of fluid in the connective tissue spaces of the mammary glands in pregnant women and in patients with certain types of disease of the breast is the result of increased permeability of the vascular walls; this, in turn, is probably caused either by the altered endocrine balance during gestation or by a hormone imbalance in patients with mastodynia and mastopathy, and primarily by hyperesterinism. The transient presence of large amounts of fluid rich in protein in the mammary tissue, observed during pregnancy and lactation, is probably related to the nutrition and function of the mammary glands whose activity is increased during these periods. The excessive accumulation of this extracellular fluid in patients with hormone imbalance and other disturbances is a pathological manifestation; its persistence causes fibrosis and hyaline degeneration of the interstitial tissue by the transformation of globular proteins in fibrous proteins and by the synthesis of solid mucopolysaccharides. There were no qualitative differences in the composition of the tissue fluids obtained from patients with benign and malignant processes.

PEDIATRICS

Neonatal Varicella: A Case Report with Isolation of the Virus. R. M. Ehrlich, J. A. P. Turner and M. Clarke. J. Pediat. 53:139-147 (Aug.) 1958 [St. Louis].

Varicella during the newborn period is uncommon, only 16 cases having been reported in which the disease occurred during the first 10 days of life. The authors present the history of an infant in whom the rash appeared on the 7th day. This is the third reported infant with neonatal varicella, on whom a complete autopsy was done, and it is the 4th fatality among 17 reported cases. In all 4 of the fatal cases the disease had its onset more than 5 days after birth. The infants born with the rash or with an early onset of the rash survived. A possible explanation for this is that in the infant who develops lesions soon after birth the viremia occurred in the mother at an earlier date. This may allow antibodies to be formed and then to pass the placental barrier to the infant, resulting in a more attenuated form of the disease. At postmortem examination of the infant studied the characteristic lesions were demonstrated in most organs. Endothelial as well as epithelial cells were involved. The spread of the virus probably occurred via the blood stream. Two conclusions can be drawn from this case: 1. Neonatal varicella may be more severe than generally thought, with a mortality of 20% as shown by the literature. 2. The onset of varicella between 5 and 10 days after birth appears to be more severe than when the disease occurs at an earlier age.

Clinical Study of Oral Phenoxymethyl Penicillin and Parenteral Procaine Penicillin G: Comparative Study of Results in 1266 Children. A. A. Mintz, C. Bashaw and L. L. Hill. A. M. A. J. Dis. Child. 96:179-183 (Aug.) 1958 [Chicago].

The recent introduction into clinical medicine of phenoxymethyl penicillin (penicillin V) provided a penicillin that is virtually insoluble and thus stable in the acid pH range of the stomach but soluble and readily absorbable in the alkaline pH range of the intestine. Reports indicate that orally administered phenoxymethyl penicillin produces blood concentrations considerably higher than an orally administered dose of the salts of penicillin G and concentrations somewhat lower than an equivalent parenterally administered crystalline dose, although the blood levels obtained with orally administered phenoxymethyl penicillin are superior to the levels obtained with comparable doses of intramuscularly administered procaine penicillin G. The group studied included 2,132 children who were admitted to the pediatric clinic with the usual infectious diseases found among a large indigent population and of whom 1,266 (59%) returned on the last day for evaluation. The patients were subjected to either of the following regimens: (1) procaine penicillin G—children less than 1 year of age were given 300,000 units intramuscularly daily, while children over 1 year of age were given 600,000 units daily for a period of 5 days and (2) phenoxymethyl penicillin —125 mg. (200,000 units) was administered orally every 6 hours for 5 days. No differences were noted as to the status of the patients after the 2 types of penicillin therapy in regard to initial clinical diagnosis, bacterial organisms isolated prior to therapy, and white blood cell counts. No pneumococci were present on repeat culture regardless of the type of penicillin used. Beta-hemolytic streptococci were still present in 30% of the patients on the 5th day regardless of therapy but were not present after the 10th day. On repeat culture as many or more Staphylococcus organisms (Staph. pyogenes var. aureus) were present after therapy as were present before. There were no significant differences in the number of side-reactions with the 2 types of penicillin.

Kwashiorkor: Report of Four Cases from Louisiana. V. M. Henington, E. Caroe, V. Derbes and B. Kennedy. A. M. A. Arch. Dermat. 78:157-170 (Aug.) 1958 [Chicago].

The protein-deficiency disease of children, referred to as kwashiorkor, has been reported from every part of Africa and from China, India, Malaya, Indonesia, Fiji, and the Philippines. It has also been reported from Hungary and Italy, from the Caribbean Islands, and from various parts of Central and South America. The 4 children presented are believed to be the first cases of kwashiorkor reported in this country. All 4 were Negro girls, ranging in age from 20 months to 11 years. The 1st and 4th patients presented findings which are regarded as reasonably typical of kwashiorkor as it is observed in equatorial Africa, while the 2nd and 3rd patients presented milder forms of the disease. The 1st patient (11 years old) had continuous vomiting and diarrhea, with passage of semiformed stools containing undigested food, ascariasis, profound inanition, generalized edema associated with hypoproteinemia and anemia, enlargement of the liver, a reddish tinge to the hair at the ends, apathy and mental retardation, and scaly follicular skin changes over the chest. The 4th patient, a very much younger child (20 months), also suffered from vomiting, ascariasis, loss of weight, generalized edema, weakness, and pronounced mental apathy. Her hair did not show a reddish tinge but was lighter, sparser, and dryer than usual Negroid hair. The 2nd and 3rd patients, sisters of the 1st, presented typical manifestations of the disease but in a milder (forme fruste) form. Inanition and apathy were conspicuous. The scaly rash present over the buttocks of the 3rd child seemed to be similar to the changes observed in the early stage of kwashiorkor. The 2nd patient had the most marked reddish tinge to her hair.

All 4 children have improved with an improved dietary regimen, though they are still below normal in weight and height, particularly the 1st child who is the oldest of the 4 patients. The 4th child has been under observation too short a time to permit conclusions, but she has improved greatly on a high-protein diet. Provision of food of high-protein and high-vitamin content by the Louisiana State Health Department has undoubtedly prevented a relapse of kwashiorkor in the first 3 of these patients. On the other hand, all the children, especially the younger ones, still eat dirt, and for this reason, plus their lack of cleanliness, intestinal parasitism still presents an unsolved problem. The authors believe that other patients in the United States have kwashiorkor, and they hope that this communication will call attention to the importance of recognizing and treating them.

Early Diagnostic Criteria of Congenital Hypothyroidism. G. H. Lowrey, R. H. Aster, E. A. Carr and others. A. M. A. J. Dis. Child. **96**:131-143 (Aug.) 1958 [Chicago].

A series of 49 cretinous patients, ranging in age from 12 months to 32 years, have been followed from 1 to 32 years. The average age at the time of diagnosis was 12 months. A survey of these patients, three-fourths of whom were female, has revealed that 54% had at least 3 prominent symptoms of their disease by the end of the first month of life and 75% by the end of the third month. For purposes of comparison, 100 normal infants were followed in the well-baby clinic for at least 6 months. The most commonly observed findings, in order of frequency, were lethargy, constipation, feeding problems which included slow feeding, choking, failure to gain weight, and lack of interest, umbilical hernia, and skin changes. Sluggishness of intestinal peristalsis was a quickly recognized characteristic of the hypothyroid patient, only 4 of the cretins in this study failing to manifest this difficulty. Respiratory distress associated with cyanosis appeared in 15 patients in the first months of life, 6 of the parents reporting cyanosis at some time during the first 24 hours after delivery and oxygen being administered to 3 of the cretins for periods exceeding 24 hours. Noisy respirations were not an uncommon complaint. Abnormal dryness of the skin was noted within the 1st month of life by one-third of the parents and within the 4th month by more than three-fourths. Thickening of the tongue to the point that it protruded from the mouth and interfered with respiration or feeding was noted in two-thirds of the infants in this series, the abnormality being observed for the most part prior to the 3rd month and always by the 5th month. Four of the patients were observed to have goiters either at birth or in early childhood. Umbilical hernia, which seldom developed later, was noted during the first week of life in two-thirds of the series. Not one of the infants had attained an expected or normal linear growth for his chronological age in comparison with tables of Stuart and Meredith. A hoarse or deep cry was noted in half of the patients, and loud or difficult breathing in a like number. The heart rate in 35% of the patients was 100 or below and was at this age indicative of true bradycardia. In 11 patients (55%) rectal temperatures persisted below 98 F (36.6 C) until therapy was instituted. Less frequently noted skin changes included pallor, 10; mottling and "coldness," 8; carotenemia ("yellow skin"), 4; and prolonged icterus neonatorum, 6. Alkaline phosphatase determinations gave results below normal in 11 patients, and after one year of age the cholesterol levels were significantly elevated in the majority of the untreated cretins. The only pertinent hematological finding was that of a moderate hypoplastic anemia in half of the patients. The evaluation of bone maturation was a valuable screening device, since every patient adequately examined by x-ray for "bone age" had easily measured retardation. The diagnosis of cretinism can usually be made, with the aid of a careful history, adequate physical examination, and a few laboratory procedures, by 3 months and certainly before 6 months of age.

Incontinentia Pigmenti (Bloch-Sulzberger's Disease). M. Lamy, R. Garcin, B. Duperrat and others. Arch. franç. pédiat. **15**:577-585 (No. 5) 1958 (In French) [Paris].

The authors report a case of incontinentia pigmenti in a female infant who at birth had 2 bullae filled with a clear fluid, one on the right hand and the other on the left leg. More bullae appeared during the following days. These lesions were very small but were associated with red papules, apparently pruriginous, varying in size from that of a millet seed to that of a lentil. At the age of 1 month the bullae had disappeared, but there was an eruption of papules of lichenoid type and occasionally verrucose, mainly on the extremities. This eruption became generalized, but the thighs and legs were particularly affected; the pattern of the eruption was definitely linear. The family history was entirely negative. Blood studies revealed a considerable eosinophilia on repeated examinations, varying from 23 to 32 per 100 cc. A skin biopsy was made and revealed the characteristic triad of bullae, eosinophilia, and dyskeratosis. Repeated bouts of the eruption occurred in the course of the following months, but with decreasing severity. The eosinophilia became less pronounced and was restored to normal (2 per 100 cc.) when the infant was 8 months old. At the age of 10 months the clinical picture again was changed, and the diagnosis of incontinentia pigmenti was made. The papular eruption was replaced by pigmentary spots of a chocolate-brown color, of spattered shape, and arranged in stripes, particularly at the sides of the thorax. The mucous membranes were not involved. The development of the infant's body, as well as her mental development, was normal. Ocular or nervous disturbances were not observed. There was only a slight delay in dentition. The skin of the infant was brittle and sensitive to sunshine.

The causation of incontinentia pigmenti is unknown. There is a general tendency to consider the condition as a congenital malformation of nevoid type. This concept is based on the appearance of the eruption at birth or during the first days of life, the occurrence of familial cases which may be rare but definite, suggesting a Mendelian dominant, and the frequent association with malformations of the eyes and the nervous system, suggesting a true congenital neuroectodermosis. Other concepts proposed include an infectious and an allergic origin. In agreement with most of the workers, the authors consider incontinentia pigmenti a dysembryoplasia, often associated with other congenital malformations, occasionally familial, the mechanism of which is unknown.

Lymphangioma of the Genitalia in Children. S. A. Gueukdjian. Pediatrics 22:247-249 (Aug.) 1958 [Springfield, Ill.].

The author reports on a 3-year-old boy with a swelling of the penis and left groin which had been present recurrently since birth, without pain or ulceration. Exploration was carried out through a left inguinoscrotal extended incision. The subcutaneous tissues down to, but not including, muscle were found to be invaded by a network of multiple cysts containing lymph. The walls of the cysts were thin, glistening, and frail. The limits of the infiltrated area were well defined. En bloc excision was carried out. A polyethylene catheter was inserted subcutaneously, and the skin was closed with interrupted silk sutures. Continuous suction was maintained for 3 days, the catheter being gradually withdrawn every day. Antibiotics were given parenterally as prophylaxis. At subsequent examination as an outpatient, the boy was considered cured; there were no signs of lymphorrhea or recurrence, up to 1½ years after the operation. Microscopic examination of the operative specimen revealed cysts lined with a single layer of endothelium and surrounded by loose fibrofatty tissue. The diagnosis was lymphangioma. There was no evidence of malignancy. Lymphangioma is an uncommon benign neoplasm of the lymphatic system. If surgical and pediatric interest were directed to it, the condition would be diagnosed more often. Localization of these tumors in the region of the groin and external sex organs is unusual and presents diagnostic problems. Most of the cases occur in childhood. Treatment is by excision, but recurrences are to be feared.

Appendicitis in Childhood: A Study of 1,358 Cases. L. A. Longino, T. M. Holder and R. E. Gross. Pediatrics 22:238-246 (Aug.) 1958 [Springfield, Ill.].

The author reports on 1,358 patients who were admitted to the surgical service of the Children's Hospital in Boston with acute appendicitis and were treated between July 1, 1944, and Jan. 1, 1957. Seven hundred forty-three patients (56%) were boys. Six hundred eleven (45%) had a ruptured appendix. Of these, 369 were less than 6 years of age, 231 were between the ages of 6 and 12 years, and 11 were over 12 years of age. The younger the child, the greater the likelihood of rupture. Only 1 patient, who was less than 2 years of age, died, a mortality rate of 0.07%. There have been no deaths in the last 12 years during which 1,309 patients were operated on. Patients with an unruptured appendix were hospitalized for less than 6 days, and those in whom the appendix had ruptured were hospitalized for about 12 days. Almost all the complications which were observed occurred in patients with a ruptured appendix. The most common complications were abscesses and other infections. Prompt appendectomy is the treatment for all children with appendicitis. Early diagnosis is of utmost importance, although in small children this may be difficult. The triad of abdominal pain, fever, and vomiting should be considered indicative of appendicitis until proved otherwise. To operate on these children with safety, adequate preoperative preparation and postoperative care are of greatest importance. The appendix was removed and the abdominal cavity drained in all the patients with ruptured appendix. Postoperative obstruction of the small intestine occurred in 45 patients; the obstruction occurred 5 to 10 days after the operation in 44, and 6 months after appendectomy and drainage in 1. Most of the immediate postoperative obstructions were managed successfully with a long intestinal tube.

The fact that nearly 50% of the patients had rupture of the appendix before the time of hospitalization is strong proof that diagnostic methods need to be improved. The early recognition of this disease would permit surgical intervention before rupture and peritoneal soiling has occurred. The most important effort that can be made in this direction is to recommend 24 to 48 hours of observation in a hospital for any child in whom appendicitis is suspected. At little expense, this allows frequent checking by appropriate members of the resident or visiting staff of the hospital. If findings suggestive of inflammation of the appendix disappear, the child generally can be sent home the following day. For one in whom the abdominal findings become more impressive under observation, operation can be performed while there is still an opportunity to do so before rupture of the appendix has taken place.

Neurological Complications of Pertussis Immunization. J. M. Berg. Brit. M. J. 2:24-27 (July 5) 1958 [London].

The sequelae after active immunization against whooping cough have ranged from transient convulsions with complete recovery to gross crippling, mental retardation, and death. The author reports the case of an 8-month-old male child who received a first inoculation of 1 ml. of combined diphtheria-pertussis vaccine containing a plain suspension of 20,000 million Hemophilus pertussis bacilli and 25 Lf of fluid diphtheria formol toxoid. Within 48 hours convulsive episodes began. At 11 months of age the child was severely retarded mentally, and the administration of 16 mg. of phenobarbitone twice daily was required to control his convulsions. At 15 months grand mal episodes became associated with the original convulsive pattern, and it was found necessary to increase the phenobarbitone dosage to 1 Gm. At 3 years the child remained grossly mentally retarded, with no speech or understanding of speech, inability to do anything for himself, and an IQ of 23 on the Griffiths mental developmental scale.

The author has reviewed a total of 107 cases in the literature, from some 25 sources, pertaining to pertussis immunization. The age of inoculation ranged from 4 days to 3 years. In 28 children a pertussis vaccine alone was used, and in 28 a combined pertussis-diphtheria vaccine. No significant difference is accorded the use of either preparation, although there is general agreement that the pertussis antigen is responsible for the reported neurological sequelae. The dosage of H. pertussis bacilli ranged from 1.5 to 45,000 million with no particular tendency for reactions to be associated with the larger doses. In 61 instances a reaction occurred with the first injection, and although the data indicate that a reaction may occur with any injection, there is a decreasing likelihood of reaction to subsequent injection, provided that previous injections have not elicited some activity. The early onset of symptoms was characteristic, although not invariable, the greater majority of reactions occurring within 12 hours. Convulsions were an almost invariable and striking feature. Paralyses were reported in 19 of the 107 cases. Death occurred within 48 hours of inoculations in 8 cases, 7 of the deaths occurring within 24 hours. Additional features, other than the neourological, included diarrhea, vomiting, cyanosis, and hiccups. Complete recovery was reported in 41 patients (38%) and presumably occurred in at least 9 other instances. A total of 31 children (29%) were reported as having physical and/or mental signs of cerebral involvement 1 month to 5½ years after immunization. Follow-up revealed a mortality of 14% (15 of 107 children). Included among the various hypotheses advanced to account for the complications are: (1) sensitization phenomenon; (2) specific toxin or toxins produced by H. pertussis; (3) constitutional predisposition in affected children; (4) pyrogens contaminating vaccines; and (5) accidental intravenous injection of vaccine.

Persistence of Fetal Ductus Function After Birth: The Ductus Arteriosus as an Avenue of Escape. H. L. Abrams. Circulation 18:206-226 (Aug.) 1958 [New York].

The author reports on 9 infants, between the ages of 6 days and 9 months, with various congenital cardiac anomalies in whom the fetal venoarterial flow through the ductus arteriosus persisted after birth. The conditions associated with persistence of fetal ductus function after birth included isolated patent ductus arteriosus with marked increase in pulmonary resistance, patent ductus arteriosus associated with congenital pulmonary disease, pulmonary vein atresia, mitral atresia, mitral stenosis, aortic atresia, interruption of the aortic arch, and preductal coarctation. In all these conditions, the pulmonary arteriolar resistance must be significantly elevated to permit flow into the descending thoracic aorta. Beyond this, the common denominator of the malformations, in which right-to-left flow through the ductus arteriosus persists after birth, is the presence of a site of obstruction to blood flow in the pulmonary vessels, left heart, or aorta at some point beyond the pulmonary origin of the ductus arteriosus but proximal to its aortic insertion. The ductus serves as an "avenue of escape" in most of these lesions; in no other way could blood leaving the right ventricle reach all or part of the systemic circulation without precipitating or increasing right or left heart failure.

That the ductus arteriosus, however, does not provide an effective method of sustaining life indefinitely in these circumstances is clear from the fact that 7 of the 9 infants died; the average duration of life was above 13 months, and 3 infants died before the age of 1 month. In one of the surviving patients, in whom surgery was not permitted, a state of balance consistent with life has apparently been reached; this patient is still alive at the age of 4½ years. The other surviving patient, who had coarctation of the aorta, with a right-to-left shunt through a patent ductus arteriosus complicated by a ventricular septal defect, was operated on. Surgical closure of the ductus and excision of the coarctated segment were followed by improvement. Closure of the ventricular septal defect is contemplated after a period of stabilization. Increased resistance in the pulmonary vascular bed is reversible in some cases of coarctation associated with reversed flow through the distal part of the ductus. This may have significant implications for all lesions in which reversal of flow through the ductus is based on the primary increase in resistance beyond the pulmonary arteriolar bed. With improved techniques of open heart surgery, complete correction for all these anatomic malformations may be feasible, and it seems reasonable to suppose that closure of the ductus arteriosus, when normal anatomic channels elsewhere have been restored, need not necessarily be a hazard despite the obvious increase in pulmonary resistance.

Familial Thalassemia and Erythremic Myelosis. I. Olshin and A. Sawitsky. Pediatrics 22:250-258 (Aug.) 1958 [Springfield, Ill.].

The authors report on a 10-year-old boy of Italian background who had been well until an attack of mumps followed by weakness, lassitude, and pallor. Two months later scleral icterus, enlarged liver and spleen, and tenderness over the sternum and long bones were noted. The findings of anemia, erythrocytosis, anisocytosis, poikilocytosis, target cells, and basophilic stippling in the patient and his parents, a shift of the saline fragility curves to the right in the parents, and anemia and erythrocytosis in a brother and a sister of the patient made it evident that the hereditary leptocytosis (thalassemia) trait was present in the family. Marked erythroid hyperplasia, however, was found in the patient's bone marrow, with many proerythroblasts and abnormal immature erythrocyte precursors. These findings were reflected in the patient's peripheral blood in which 100 nucleated erythrocytes were counted for every 100 leukocytes. The presence of atypical, primitive erythrocyte precursors in the marrow and peripheral blood and the late onset of symptoms in the patient made it unlikely that the disease was thalassemia but rather suggested a more malignant process, namely, malignant erythrocytosis (Gugliemo's disease).

Treatment of the patient's condition with cyanocobalamin (vitamin B_{12}), folic acid, and cortisone was ineffective. Monthly blood transfusions were required to maintain the concentration of hemoglobin at about 8 Gm. per 100 cc. Splenectomy was followed by transient improvement for the next 3 months. Myeloblastic proliferation then occurred in the bone marrow and in the peripheral blood. The myeloid phase was suppressed by the administration of mercaptopurine. Transfusions were continued as required. Twelve months after the onset of the disease, an area of nontender induration occurred in the right cheek. Six months later a biopsy of this mass revealed malignant reticulum cells interspersed with immature hematopoietic elements, which were considered characteristic of "erythroblastoma." Still 3 months later the patient sustained a mild injury of the left elbow, which was followed by hemarthrosis and subluxation of the joint and was complicated by an infection of the joint with Bacteroides subtilis. Intensive antibiotic therapy for several months was required to control the infection. Moniliasis of the mouth occurred and subsided after topical and systemic treatment with nystatin, but congestive cardiac failure, probably secondary to anemia and prolonged treatment with large doses of steroids, resulted in death.

Autopsy revealed erythroblastic infiltration of the bone marrow, liver, lungs, lymph nodes, and heart. Increased amount of hemosiderin was also observed. The gastrointestinal tract revealed areas of hemorrhagic necrosis of the submucosa and invasion of this tissue by leukemic cells, polymorphonuclear cells, and yeasts. There was evidence of severe degrees of systemic mycosis. In this patient with familial thalassemia a myeloproliferative disorder with bidirectional involvement occurred; the inherited red blood cell defect probably was the cause of the predominant expression of the disorder in the erythroid system. With a growing awareness of the hazards associated with prolonged steroid and antibiotic therapy, it became evident that many of the patient's clinical and pathological manifestations, such as the infection of the elbow joint, the monilial infection of the mouth, and the widespread systemic mycotic infiltrations revealed by autopsy, were secondary to these therapeutic agents rather than to the primary disease.

Rubella: Demonstration of Neutralizing Antibody in Gamma Globulin and Re-evaluation of the Rubella Problem. S. Krugman and R. Ward. New England J. Med. 259:16-19 (July 3) 1958 [Boston].

Contradictory results reported about the efficacy of gamma globulin in the prevention of rubella induced the authors to investigate the presence of neutralizing antibody in ordinary gamma globulin, convalescent-phase rubella plasma, and gamma globulin prepared from plasma of patients convalescent from rubella. The serum, containing rubella virus taken from patients on the first day of rubella rash, was mixed with equal portions respectively of ordinary gamma globulin, of convalescent-phase rubella plasma, of convalescent-phase rubella gamma globulin, and of normal human serum. Each of the 4 mixtures was inoculated into 4 comparable groups of 6 presumably susceptible children. The material was given intramuscularly in a dose of 1 ml. Five of 6 children who received rubella serum plus normal serum contracted typical rubella after incubation periods ranging from 15 to 21 days. One of 6 children receiving virus and ordinary gamma globulin acquired characteristic rubella on the 17th day. In the group receiving convalescent-phase plasma mixed with virus, rubella developed in 1 subject 14 days after inoculation. All 6 children who received the mixture of virus and convalescent-phase gamma globulin remained well. Thus, it appears that passive protection against rubella can best be achieved by early administration of large doses of gamma globulin. Future controlled field studies will have to define the precise dosage. In the meantime, gamma globulin in a dose of 0.15 to 0.20 ml. per pound of body weight appears to be indicated. It has been the practice to give 20 ml. intramuscularly to women exposed during pregnancy. If convalescent-phase rubella gamma globulin is available, 10 ml. given intramuscularly should be sufficient.

The authors also comment on recent prospective studies assessing the risk of fetal abnormality. Evidence suggests that the potential risk is increased approximately 6 times if rubella is acquired in the first trimester of pregnancy. The prevalence of congenital malformations has been estimated to be approximately 12%. Therefore, it is incumbent upon the physician to consider each case in the light of its individual merits. The deliberate exposure of young girls to rubella is recommended. One attack of this benign disease of childhood is generally followed by immunity. At the present time this procedure is the best method of preventing the serious effects of rubella in the offspring.

Myasthenia Gravis in Children. R. L. Sampayo and L. C. Stigol. Arch. argent. pediat. 29:154-167 (April) 1958 (In Spanish) [Buenos Aires].

Myasthenia gravis in infants and children is more frequent than is generally assumed. A diagnosis is made by the results of the Prostigmin test, which consists of the intramuscular injection of neostigmine (Prostigmin) bromide in doses ranging from 0.07 to 0.1 mg. in newborn infants and of the subcutaneous injection of 0.5 mg. of the drug in children up to the age of 10 years. The myasthenic syndrome is observable in the newborn infants of mothers who are suffering from the disease, whether or not the mothers have received Prostigmin. Palpebral ptosis and disorders of deglutition appear during the first 48 hours after birth, and the infant is constantly moaning. On the administration of Prostigmin by mouth, the patient reacts immediately and favorably. After 15 days the treatment is discontinued and needs not be resumed. Both in infants and in children myasthenia gravis may start with acute symptoms and may be complicated by more or less serious bronchopulmonary diseases. The symptoms, which are similar to those observed in adults, consist mainly of fatigability and progressive paralysis of certain muscles, especially those of the face, lips, tongue, throat, and neck. There are no sensory disturbances. The cerebrospinal fluid is normal, and the patient remains completely alert to his environment.

The subjects of this report were 2 girls, aged 5 and 8 years. Ptosis appeared in both patients at the age of 2 years. It was bilateral in one case and unilateral in the other. In both patients it was total. One of the patients had been treated with Prostigmin but with dosage that the parents did not know. In both patients the Prostigmin test and Jolly's myoelectric test for myasthenia gravis gave positive results. Treatment has been given to only one of the patients. It consisted of the administration of pyridostigmine (Mestinon) bromide in doses of 60 mg. 3 times a day. All the symptoms of myasthenia, including palpebral ptosis, disappeared. The patient is now in a satisfactory state of general health.

The authors believe that pneumomediastinum as a diagnostic procedure for the presence of tumoral thymus is unnecessary and that thymectomy is ineffective in children. Thymectomy is a very serious operation, the results of which are no better than those obtained with medical treatment with Prostigmin.

Acquisition of Intestinal Protozoa and Helminths by Young Children in a Typical Village of Lower Egypt. R. E. Kuntz and D. K. Lawless. Am. J. Trop. Med. 7:353-357 (July) 1958 [Baltimore].

The authors studied 81 children weekly for their intestinal fauna over a period of 16 weeks at Sindbis, a village representative of the delta area of lower Egypt. Of the 81 children, 23 were between the ages of 1 and 6 months, 30 were between the ages of 13 and 24 months, and 28 were between the ages of 26 and 47 months. The intestinal fauna of the youngest group was limited quantitatively and qualitatively, and only flagellate protozoa were detected. Examination of stool specimens obtained from the children between 13 and 24 months of age indicated that the period between 15 and 20 months was very important from the standpoint of general establishment of intestinal fauna in a child. Flagellates increased in number, amebas were detected, and the eggs of Ascaris, Enterobius, and Hymenolepis nana were passed with the feces. At the age of 16 to 18 months Entamoeba histolytica became established, the rate of infection increasing rapidly during the next 2 years. In the oldest age group, protozoan and helminth populations increased markedly, and none of the 28 children in this group escaped invasion by intestinal fauna.

A total of 9 species of protozoa and, in addition, both the large and the small races of E. histolytica and 6 different helminths were found in the latter age group by the time this study was terminated. Although Sindbis lies in an endemic area, neither of the 2 schistosomes common to Egypt were found.

Penicillin in the Treatment of Streptococcal Infections: A Comparison of Effectiveness of Five Different Oral and One Parenteral Form. B. B. Breese and F. A. Disney. New England J. Med. 259:57-62 (July 10) 1958 [Boston].

The authors treated 611 children, between 1 and 17 years of age, who had infections due to beta-hemolytic streptococci, with 1 form of parenterally administered penicillin and 5 different preparations given orally in order to determine their effectiveness against streptococcic infections. Of the 611 patients, 122 received a total dose of 600,000 units of benzathine penicillin G, 237 were given a total dose of 8 million units of phenoxymethyl penicillin (penicillin V), 114 received a total dose of 8 million units of buffered potassium penicillin G, 66 were given a total dose of 7.5 million units of buffered potassium penicillin G and probenecid, and 72 received 5 million units of buffered potassium penicillin G and probenecid suspension. These children were observed for 2 months after the institution of therapy. No patient was included in the study who did not have a throat culture at least 11 days after the onset of therapy. Acute tonsillitis or pharyngitis was diagnosed in almost 70% of the patients; 19% were carriers; 5.4% had cervical adenitis and 4.7% scarlet fever. The remaining patients had infections, such as otitis media, sinusitis, and cellulitis. Uniformly good immediate results were obtained with all the preparations tested.

The ultimate effectiveness of these drugs, as judged by the cure rate at the end of 2 months, the relapse rate within 25 days, and the proportion of strongly positive cultures obtained from patients with relapses, indicated that a single intramuscular injection of 600,000 units of benzathine penicillin G was superior to the preparations given orally. The parenterally administered penicillin preparation may have the additional value of preventing some subsequent unrelated streptococcic infection. Among the orally administered drugs no single preparation was significantly superior to the others. The choice of which one to prescribe is incumbent on the physician. The skin reactions which were observed after probenecid had been used for more than a week were harmful, although not serious. Parenteral administration of penicillin is cheaper than the administration of oral preparations and is not associated with the problems encountered with the latter. Benzathine penicillin G given in a single dose of 600,000 units intramuscularly is the authors' first choice in the treatment of streptococcic infections in children. Its chief disadvantage lies in the painful local reactions frequently observed and the psychological trauma engendered by the use of a needle.

Therapeutically, but not prophylactically, the oral preparations used were almost as effective as the one administered parenterally. The choice of which oral drug to select should be based on factors other than effectiveness, since there is no evidence to indicate the therapeutic superiority of any one product. Since cost is often the most important factor, among the oral preparations tested, buffered potassium penicillin G in a dosage of 800,000 units daily for 10 days is the first choice for oral treatment of streptococcic infections in children.

OPHTHALMOLOGY

Metastatic Carcinoma of the Retina: Report of a Case and the Pathologic Findings. R. J. Kennedy, W. D. Rummel, J. L. McCarthy and J. B. Hazard. A. M. A. Arch. Ophth. 60:12-18 (July) 1958 [Chicago].

Metastatic carcinoma of the eye, involving the retina alone, is an extremely rare lesion, only 2 cases having been previously reported. The authors report on a secondary carcinoma of the macula of the right eye, the primary site of which was the rectosigmoid. The patient underwent surgery for a grade 3 adenocarcinoma of the rectosigmoid. Ophthalmoscopic examination 3 months later revealed that the lesion in the macular region of the right eye, which had been previously diagnosed as metastatic carcinoma of the choroid with macular involvement, had enlarged, with new vessels coursing over it. Enucleation was done, and sections revealed a neoplasm involving the retina which was histologically similar to that found in the rectosigmoid.

Gross sections revealed a small discoid, grayish-white, nonpigmented lesion at the posterior pole, elevating the retina but not distending the choroid. The anterior segment and the posterior sections were within normal limits. The sections adjoining the nasal border of the lesion showed a pink-staining acellular fluid elevating the retina from the retinal pigment layer. Temporal to the latter section, the tumor mass involved the retina, which had lost its architecture, exhibiting necrosis and degeneration of the various layers and the adjoining subretinal space. The choroid was normal save for focal sites of perivascular inflammation and hyperemia in the region of the lesion. The neoplasm was formed of atypical stratified-columnar epithelial cells in small nests with lumens and separated by patches of necrotic tumor material. No tumor growths were found in the choroid, sclera, optic nerve, or vitreous, and there were no implantation growths. The patient died within 3 months, possibly because of generalized metastases.

Audiometric Studies on Patients with Degeneratio Pigmentosa retinae. B. Alberth, A. Bálint and A. Kósa. Klin. Monatsbl. Augenh. 132:797-806 (No. 6) 1958 (In German) [Stuttgart, Germany].

Audiograms were obtained with the aid of an audiometer from 11 men and 6 women with retinitis pigmentosa, who were examined at the ophthalmological clinic of the University in Debrecen, Hungary. In 15 of the 17 patients the disease was acquired (autonomic), and in 2 it was primary (hereditary). Mild to severe degrees of hardness of hearing for the higher sounds were observed in all the patients. An additional selective loss of the power of hearing was observed at 4096 cps. These 2 characteristics suggested that the hardness of hearing originated in the nervous system. The impairment of hearing paralleled the narrowing of the visual field rather than the decrease of visual acuity. It was the authors' impression that the changes in visual acuity, which resulted from combined treatment of 10 patients with vitamins A, B_1, and C, liver, and various vasodilators and placenta implantations according to Filatow's technique, paralleled the changes in hearing in most of these patients. It was not possible to establish a precise relationship between the vision (visual field) of one eye and the hearing of the homolateral or contralateral ear. Lateralization, i. e., the possibility of a certain relationship between one eye and the contralateral ear, which has been suggested by some workers, remains an open question.

The fact that a loss of hearing was established in all the patients with pigmentary degeneration of the retina favors—in addition to many other reasons—the concept that the autonomic pigmentary degeneration of the retina is likewise neither an isolated disease of the eye nor the result of a local cause, but that it is rather closely connected with the central nervous system. Both the hereditary and the autonomic type of the disease may develop as concomitant manifestations resulting from a lesion of a central anatomic structure not yet identified.

THERAPEUTICS

The Use of Hydrocortisone in the Treatment of Tuberculous Meningitis. R. L. Cranny and V. C. Kelly. A. M. A. J. Dis. Child. 96:165-168 (Aug.) 1958 [Chicago].

The Reddy modification of the Reddy-Jenkins-Thorn technique was used to determine the levels of 17-hydroxycorticosteroids (17,21-dihydroxy-20-ketosteroids) in several samples of spinal fluid withdrawn 4 hours after the oral or the parenteral administration of hydrocortisone. Extremely small amounts of detectable Porter-Silber chromogens were present in the normal control spinal fluid samples. However, 17-hydroxycorticosteroids (17-OHCS) were present in all the samples from the patient with tuberculous meningitis after administration of hydrocortisone either orally, intramuscularly, or by both routes. They were also detected in 2 children without tuberculous meningitis 2 and 4 hours after the intravenous administration of hydrocortisone. A positive Porter-Silber reaction was not forthcoming after the administration of 100 mcg. of PAS and of isoniazid. In the single case cited, no evidence of spread of tuberculosis induced by hydrocortisone was noted. An interesting, though as yet unexplained, observation was the finding of a high concentration of 17-OHCS in the spinal fluid of a patient with tuberculous meningitis 2½ months after hydrocortisone therapy had been discontinued—a finding which has been attributed to either a continued release of steroids that had accumulated in the tissues or the increased permeability of the "blood-brain barrier" to steroids during the acute and convalescent stages of different diseases.

Clinical Studies on Tebamin. K. Tørning, K. A. Jensen and I. Kiaer. Acta tuberc. scandinav. 35:87-100 (No. 2) 1958 (In English) [Copenhagen].

It has been demonstrated that, when aminosalicylic acid is given in conjunction with isoniazid or streptomycin, the development of bacterial resistance to these 2 valuable drugs may be prevented for a long time. For that reason aminosalicylic acid today is indispensable in the chemotherapy of tuberculosis. Unfortunately, oral administration of aminosalicylic acid often entails such marked dyspeptic disturbances that long-term treatment becomes difficult, if not impossible. Furthermore, during ambulant chemotherapy there is always a possibility that unwise patients may stop taking the drug, without informing the physician, thereby exposing themselves to the serious risk of the development of chemoresistant tubercle bacilli. The authors for several years experimented with a derivative, the phenyl ester of aminosalicylic acid, known as Tebamin. The first preparation employed in these tests was micronized Tebamin in tablet form. The results of combined treatment with Tebamin tablets (5 Gm. 3 times daily) and isoniazid were promising, as far as prevention of the development of resistance was concerned. The level of free aminosalicylic acid in the blood was, however, rather low. Other Tebamin preparations were tried, and now for more than a year the authors have used Tebamin in the form of a powder, consisting of finely micronized Tebamin treated with a surface-active substance and mixed with an equal part of sucrose. A fine suspension is obtained when the powder is carefully mixed with water or milk. After oral administration, some 80% is absorbed. Preliminary tests on healthy subjects and on patients have demonstrated that Tebamin is nontoxic and that it causes only negligible dyspeptic disturbances.

The main object of the studies described was to investigate the capacity of Tebamin to retard the development of resistance to isoniazid. For this study, 22 patients were selected and were treated daily with 4 mg. of isoniazid per kilogram of body weight in 3 divided doses, together with Tebamin in doses of 4 Gm. given 3 times a day after meals. With this treatment there was no increase in the resistance of tubercle bacilli to the 2 drugs, Tebamin and isoniazid. Furthermore, direct smear and culture of the sputum or culture from gastric lavage showed that all the patients had become free from tubercle bacilli, with the exception of one who was treated for 9 weeks only. The observation period, throughout which weekly examinations of the sputum or gastric lavage were made, was in 14 cases longer than 30 weeks; in 7 cases it was between 18 and 29 weeks; and in 1 case it was only 9 weeks. The studies proved that Tebamin is suitable for combined treatment with isoniazid. When this therapy is employed, only minimal dyspeptic disturbances arise, and the development of resistance of tubercle bacilli is prevented.

Nil nocere!: Deafness Caused by Intramuscular Administration of Neomycin. S. Körtge-Stöppler and G. Mittag. München. med. Wchnschr. **100:** 1189-1192 (Aug. 8) 1958 (In German) [Munich, Germany].

The authors report on 2 men and 2 women in whom severe disturbances of hearing resulted from the intramuscular administration of neomycin. Two of the patients were less than 30 years of age. The first patient had an inflammation of the urinary passages and was given 0.5 Gm. of neomycin intramuscularly twice a day for 5 days; the total dose of the drug administered was 5 Gm. On the 6th day she complained of tinnitus and difficulty of hearing. Administration of the drug was discontinued, but the disturbance became worse. The excitability of the apparatus concerned with maintaining equilibrium remained normal in both ears. The second patient who had chronic renal disease received the same neomycin therapy as the first patient and complained of tinnitus and poor hearing on the 9th day after the institution of the treatment; the difficulty of hearing increased within the following 11 days. The third patient had a recurrent furunculosis associated with cardiac disease for which he was treated with neomycin for 8 days; the total dose of the drug given intramuscularly was 7.5 Gm. Difficulty of hearing which began on the 11th day after the institution of neomycin therapy progressed to deafness; the excitability of the vestibular apparatus remained normal. The fourth patient had osteomyelitis and was treated with neomycin for 25 days; the total dose of the drug given intramuscularly was 12.5 Gm. Ten days after the cessation of treatment and on the 35th day after its institution, the patient complained for the first time of difficulty of hearing. The caloric excitability of the apparatus concerned with equilibrium remained normal in both ears.

These findings showed that the period elapsing from the institution of neomycin therapy to the onset of the disturbances of hearing was short. The difficulty of hearing increased after the withdrawal of the drug. Since there was evidence of a renal disorder (partly only mild) in all 4 patients, it has been emphasized again that intramuscular administration of neomycin is contraindicated in patients in whom renal disease is merely suspected.

Open Healing of Tuberculous Cavities: Results in 40 Patients Treated Conservatively. T. M. Wilson, L. Doyle and M. P. Gardiner. Brit. M. J. 2:87-90 (July 12) 1958 [London].

The authors report on their experience with indefinite prolonged chemotherapy in the treatment of 40 patients with advanced pulmonary tuberculosis with persistent cavitation, who had been observed for periods ranging from 1½ to 5 years. Thirty-seven of the patients had been adjudged by virtue of age, advanced disease, or poor respiratory function as unsuitable for surgery, the remaining 3 patients having refused surgery. All the patients were sputum positive; 35 had received no treatment, and 5 had had previous chemotherapy with drug combinations considered unlikely to produce resistant organisms. Thirty-two of the patients received a triple drug regimen—streptomycin, PAS, and isoniazid—during the first year of treatment. The other 8 patients received varying drug combinations because of inability to tolerate PAS, partial nerve deafness, or allergic reaction to PAS. Only one of the patients did not continue to take antituberculosis drugs.

All the patients showed marked clinical and roentgenologic improvement, which usually continued into the second or third year of treatment. Tomograms showed marked resolution of disease, although multiple cavities persisted in 28 patients. Thin-walled, cyst-like cavities persisted in 25 patients; the residual cavities were apparently thick-walled in 12; and in 3 both varieties persisted. The rate of sputum conversion was rapid; 37 patients became sputum negative within 6 months and 2 during the 7th and 9th month; the last patient remained intermittently positive for 15 months. One other patient produced a solitary positive sputum culture during the third year of observation.

Chemotherapy of Tuberculosis: III. Verazide in the Treatment of Pulmonary Tuberculosis. S. D. Rubbo, L. C. Rouch, J. B. Egan and others. Am. Rev. Tuberc. 78:251-258 (Aug.) 1958 [New York].

The authors conducted a clinical trial of 3,4-dimethoxybenzal isonicotinylhydrazone (Verazide) in 3 hospitals in Australia, in which the response in 2 groups of patients with pulmonary tuberculosis was studied for 3 months. One group of 79 patients received Verazide and streptomycin, and a control group of 75 patients was given isoniazid and streptomycin. Verazide was given in a dose equivalent to 20 mg. per kilogram of body weight by mouth as enteric-coated tablets in divided doses twice daily after meals. Sixty-four of the 75 control patients were given 8 mg. of isoniazid per kilogram of body weight daily in 2 divided doses, and 11 received 300 mg. of isoniazid daily irrespective of their weight. All the patients received 1 Gm. of streptomycin, either on alternate days for the entire trial period or daily for 6 weeks and thereafter 3 times a week. The results, assessed on clinical, roentgenographic, and bacteriological criteria, showed that no difference in effectiveness could be seen between Verazide and isoniazid. However, Verazide, when given in uncoated tablets, caused toxic reactions, such as drowsiness, slurred speech, and occasionally blurred vision and nausea. These manifestations of intoxication of the central nervous system were not observed with isoniazid; they did not occur when Verazide was administered in enteric-coated tablets. These toxic effects of Verazide were attributed to the rapid absorption of veratric aldehyde released during partial acid hydrolysis of Verazide in the gastric juice. On the evidence available, no chemotherapeutic or pharmacological advantage can be claimed for Verazide, when compared with isoniazid, for the treatment of pulmonary tuberculosis.

Oral Treatment of Diabetes: Trial of Phenylethyldiguanide (D. B. I.). G. H. Hall, M. F. Crowley and A. Bloom. Brit. M. J. 2:71-74 (July 12) 1958 [London].

In the course of study to determine the effectiveness of phenylethyldiguanide (D. B. I.) as a hypoglycemic agent in diabetes of all grades of severity, to gauge its side-effects, and to compare its mode of action with that of insulin and tolbutamide, 40 diabetic patients were admitted to the wards. The subjects ranged in age from 18 to 78 years, with a mean average of 57 years. A significant fall in blood sugar levels was observed in 24 of the 40 patients in response to a single 150-mg. dose of D. B. I. The response began to be apparent at 4 hours and reached its maximum at 6. Although there was no significant change in the blood sugar levels during the period of dietary restriction alone, administration of D. B. I. led to a progressive fall in the mean blood sugars, the lowest level being attained by the 6th day of treatment. The urinary output of sugar reflected the blood sugar levels, and there was no evidence of an altered renal threshold. The 5 patients whose life depended on the administration of insulin developed ketosis very rapidly when insulin was withdrawn; their condition was not alleviated by the administration of D. B. I., although there was a small fall in the blood sugar level. In the remaining 35 patients only occasional positive "acetests" were recorded prior to treatment. After the administration of D. B. I. 11 of the 35 exhibited intermittent acetonuria of greater frequency and concentration than prior to treatment, although normoglycemia and aglycosuria prevailed. No effect of D. B. I. could be demonstrated on either plasma amino-acid nitrogen or serum inorganic phosphorus values. An inverse relationship was found to exist regarding the severity of diabetes and the response to D. B. I., patients with milder or moderately severe diabetes showing a fall in blood sugar level in response to the administration of D. B. I. Of the 14 newly diagnosed diabetics, 12 exhibited a good hypoglycemic response to D. B. I., and 5 of these did not have a relapse when D. B. I. was withdrawn. Of the patients with diabetes of long standing, 17 showed some hypoglycemic response, but none could subsequently be managed by diet alone, the impression being that D. B. I. was more effective in diabetes of recent onset. No fewer than 26 of the 40 patients developed gastrointestinal symptoms while receiving the drug; these symptoms abated upon discontinuance of the therapy. In 2 patients in whom tolbutamide had been employed unsuccessfully, D. B. I. was effective in lowering the blood sugar level. In 3 other patients in whom D. B. I. had produced normoglycemia and in whom treatment was discontinued because of nausea and vomiting, tolbutamide was slower and less effective in reducing the blood sugar value. It was impossible, as previously planned in 25 of the 40 patients, to administer D. B. I. for 6 weeks because of unpleasant side-effects or because an adequate fall in blood sugar level had not been realized. Six of the remaining 15 patients are still receiving D. B. I., and their condition is satisfactorily controlled.

Treatment of Acute Leukemia in Adults with Massive Doses of Prednisone and Prednisolone. N. B. Granville, F. Rubio Jr., A. Unugur and others. New England J. Med. 259:207-213 (July 31) 1958 [Boston].

The authors report on 20 consecutive cases of acute leukemia in adults treated with massive doses of prednisone. The first 10 patients received 1,000 mg. per day; the second 10 patients received 250 mg. per day. Prednisone and prednisolone were used interchangeably and were given orally in doses of either 250 mg. every 6 hours or 125 mg. every 12 hours for a period of 2 weeks, after which time the dosage was carefully reduced to a maintenance dosage of 5 to 50 mg. per day. Only 3 of the patients treated with 1,000 mg. of prednisone per day were able to tolerate the medication for the entire 2-week period, the drug being withdrawn in 5 cases because of undesirable side-effects; 2 patients died in less than a week after the institution of therapy. The 250-mg.-per-day regimen was better tolerated, 9 out of 10 patients receiving the full course for 2 weeks. Three complete remissions (hematological, clinical, and bone marrow) and 1 partial remission occurred in the 1,000-mg. group and 2 complete remissions and 1 partial remission in the 250-mg. group. Remarkable symptomatic improvement was evident within 24 to 48 hours of treatment in most patients, the outstanding changes including the development of a striking sense of well-being, a marked increase in appetite, and, objectively, defervescence and decreased bleeding. Since corticosteroids or corticotropin (ACTH) had been employed prior to massive prednisone therapy in 2 instances and since a short course of mercaptopurine therapy had been given to 3 patients in the 1,000-mg. group in whom complete remission was noted, the value of prednisone could not be fully assessed. No previous therapy was noted in the 250-mg. group; however, the single clear-cut remission appeared only after a brief course of mercaptopurine therapy. Five of the patients in the 1,000-mg. group had an undesirable side-effect—namely, the appearance of an agitated depression bordering on frank psychosis—which did not occur in any of the patients in the 250-mg. group. In the instances in which relapse occurred, it was not possible to induce a second remission with massive prednisone therapy either singly or in combination with mercaptopurine. Although the percentage of remissions (25%) cannot be considered very striking, it does compare favorably with other therapeutic methods. The therapy with massive doses of prednisone appeared to be at least as effective as that with mercaptopurine, and in the 250-mg. dosage it seemed least injurious.

Hemodialysis: Technique, Effect and Indications. S. Gjørup, O. Munck and J. H. Thaysen. Ugesk. læger 120:893-897 (July 10) 1958 (In Danish) [Copenhagen].

Hemodialysis is regarded as a valuable and at times indispensable means of treatment of grave acute renal insufficiency. Conservative treatment is of fundamental importance in all cases independently of their duration and is not made superfluous by hemodialysis. In recent years it has become the practice to dialyze early in the course of uremia, and it is recommended that patients with acute renal insufficiency be transferred to a special dialysis section, at the latest 3 days after the onset of uremia. The dialyses, carried out to date, have shown that the treatment is tolerated surprisingly well even by extremely ill and older arteriosclerotic patients. If there is an acute reversible renal disease of such severity that hemodialysis is indicated, contraindications will rarely be absolute. In more recent dialysis of patients with hypertension, the blood pressure has been regulated by hypotensive substances. In patients with grave uremia, dialysis is performed in spite of bleeding from mucous membranes. The uremic changes in the mucous membranes disappear to a great extent after one dialysis, so that possible repeated treatment is tolerated without complications of this kind. The main indication for hemodialysis is wholly or partly reversible renal insufficiency of acute onset, especially shock kidney. There seems now to be agreement that, other things being equal, frequent dialyses to prevent grave, long-continued uremia lead to fewer complications both during the dialyses and during the continued convalescence.

Treatment of Cancer of the Prostate with "Depot" Estrogens. D. Salsano and M. Alpi. Minerva med. 49:2367-2370 (June 13) 1958 (In Italian) [Turin, Italy].

Estradiol valerate was administered by injection to 14 patients with cancer of the prostate, 5 of whom had not previously received any chemotherapy. The drug was administered at varying dosages for a period of from 3 to 8 months. The most efficacious dosage consisted of 20 mg. given every 10 days. However, in some instances a dosage of 10 mg. given every 7 days was sufficient. Subjective improvement in those patients who had not previously received any chemotherapy became perceptible 3 or 4 days after the onset of chemotherapy. There was also an improvement, although to a lesser extent, in the other patients. Subjective improvement affected the state of well-being, there being a decrease in pain in joints and of nerves, daily and nightly pollakiuria, tenesmus, and dysuria. Objective changes consisted in change of the complexion from pale to pinkish, gain in body weight, and appearance of gynecomastia. Vesical residuum, if present, decreased or disappeared after a month of drug treatment. At the beginning of chemotherapy, estradiol valerate affected only insignificantly the morphologic characteristics of the neoplastic lesion of the prostate, but in 7 patients who received more than 250 mg. of the drug the cancerous mass changed in consistency from a hard to a fibrinous tissue without any change in the total size of the prostate. Chemotherapy benefited for 5 months one patient who had cancer of the prostate in an advanced stage, accompanied by bone metastases; afterward the condition of this patient deteriorated. The tolerance of the patients to the drug was good and, in the opinion of the authors, was superior to all other preparations of estrogens. It is suggested that the interval between 2 succeeding administrations of the drug be shortened from 10 to 7 days for large doses (20 mg.) and from 7 to 5 days for small doses (10 mg.), respectively, whenever the original symptoms relapse.

Intraperitoneal Neomycin in the Treatment of Acute Bacterial Peritonitis. H. G. Greene. Surg. Gynec. & Obst. 107:169-172 (Aug.) 1958 [Chicago].

Twenty of the group of 1,529 patients subjected to laparotomy developed acute bacterial peritonitis of such severity that the usual antibiotics were considered inadequate, and the patients were, therefore, given neomycin intraperitoneally. The patients, 13 of whom were male, ranged in age from 5 to 91 years, with a median age of 56 years. Nine had perforated appendixes; 6 had perforations of other viscera; and 5 had other lesions. No toxic effects of the drug were noted. Seven deaths (35%) occurred, 6 of the patients succumbing from causes other than peritonitis. The median hospital stay was 3 weeks. Sixteen patients suffered postoperative fever beyond the first 3 hospital days, the longest febrile course lasting 34 days and the median being 9 days. Six of the 13 survivors developed postoperative complications, 4 of them having wound abscesses, 1 having a pelvic abscess, and 1 a dehiscent abdominal wound. The original peritoneal culture showed no growth in 3 patients. In 5 patients a bacterial species was present; 8 patients had 2 species, and 4 had 3. The most common pathogens were those of the coli-aerogenes group which were present in 13 patients, followed closely by the streptococci of the viridans groups which were present in 7. In view of the innocuousness of this type of therapy and of the low mortality rate (5%) from infection, neomycin administered intraperitoneally in moderate-sized, divided doses is recommended as an adjunct to surgery for patients with severe acute bacterial peritonitis.

PATHOLOGY

A Comparison of Results Obtained from Transplantation and Replantation Experiments Using Syrian Hamster Teeth. H. I. Myers and V. D. Flanagan. Anat. Rec. 130:497-507 (March) 1958 [Philadelphia].

The authors performed transplantation and replantation experiments in 30-day-old Syrian hamsters which were anesthesized with intraperitoneally injected pentobarbital. The 3 molar teeth in these animals were fully erupted, and the roots were essentially fully formed. Bilateral mandibular second molars were extracted and replaced immediately in the socket in 15 animals. Sixteen litter-mate animals were used for the transplantation experiments. In each case, bilateral mandibular second molars of animal A were extracted and placed in sterile sodium chloride solution. Then bilateral second molars of animal B were extracted and also placed in sterile sodium chloride solution. The respective teeth of animal A were then placed in the sockets of animal B, and the teeth of animal B were placed in the sockets of animal A. These paired animals were kept in the same cage. The animals in each case were awake shortly after the surgical procedure and were quite alert within 1 hour. After 30 days the animals were killed; the mandibles were removed and placed in 10% formalin for 2 weeks. The tissues were electrolytically decalcified, paraffin embedded, and cut; every 10th section was mounted and stained with hematoxylin and eosin.

The success of the experiments was judged by the extent of the viability of the pulp, degree of attachment of the peridental membrane, amount of migration of the epithelial attachment apically, and extent of root resorption. Pulp, epithelium, and peridental membrane tissues proved to have the inherent capacity for complete regrowth. The pulpal regrowth occurred with greater difficulty than the regrowth of the other elements. Since regrowth occurred as well in the transplantation experiments as in the replantation experiments, no evidence of tissue incompatibility was noted. It would seem, therefore, that it is just as feasible to transfer a tooth from one hamster to another as it is to replant a tooth in the same hamster.

Tuberculosis Antibodies in Patients with Boeck's Sarcoid. W. Müller, K. Wurm and H. Reindell. Beitr. Klin. Tuberk. 118:229-243 (No. 4) 1958 (In German) [Berlin].

The authors performed hemagglutination and hemolytic modification tests for tuberculosis antibodies, according to Middlebrook and Dubos' technique, on serums obtained from 111 patients with sarcoidosis, from 60 patients with active pulmonary tuberculosis, from 28 patients with tuberculosis of lymph nodes, and from 50 normal persons. Tuberculosis antibodies were detected significantly more frequently in the serums obtained from patients with sarcoidosis than in those obtained from normal persons. Tuberculosis antibodies were detected less frequently in the serums of patients with sarcoidosis than in those of patients with pulmonary tuberculosis and tuberculosis of lymph nodes. No relationship between the occurrence of tuberculosis antibodies in the serums of patients with sarcoidosis and the stage of the disease, its activity, course, and duration, could be observed. Nor was any unequivocal parallelism between tuberculin sensitivity of the skin and the occurrence of serologically detectable circulating tuberculosis antibodies found. There was no relationship between the changes in the serum protein levels (such as increases in alpha and gamma globulin contents) in the serums of patients with sarcoidosis and the occurrence of tuberculosis antibodies in these serums.

The increased occurrence of tuberculosis antibodies in the serums of patients with sarcoidosis may be considered the result of a reaction to Mycobacterium tuberculosis. The serologic findings, therefore, seem to support the concept of tuberculous causation of sarcoidosis. An attempt was made to interpret the phenomenon of a weak or absent skin reaction of patients with sarcoidosis to tuberculin as a genuine dissociation between the cell-bound tuberculosis autibodies, which are responsible for the skin reaction, and the circulating antibodies, the presence of which has been demonstrated serologically. The reduced content of cell-bound antibodies in the skin is an immunological defect, which depends on a disturbance either of the formation or of the transportation of the cell-bound tuberculosis antibodies, while the formation of the circulating antibodies may be normal or increased.

RADIOLOGY

Interstitial Irradiation of the Pituitary Body With Yttrium 90: Indications, Technique, and Results. A. M. Dogliotti and A. Ruffo. Minerva med. 49: 2383-2389 (June 16) 1958 (In Italian) [Turin, Italy].

Destruction of the pituitary body by interstitial irradiation with radioyttrium (Y^{90}) was carried out in the treatment of 43 patients with advanced neoplastic disease. In 22 the diagnosis was carcinoma of the breast. The treatment consisted in implanting 3 small rods of Y^{90} through the left nostril into the pituitary body. There was no operative mortality, but there was one postoperative death attributed to meningitis. Autopsy on 3 patients revealed that the extent of destruction around the Y^{90} rods reached an area of from 3 to 4 mm. It is probable that Y^{90} permanently inhibited the function of the nonnecrotic cells. During the 30 days immediately after the operation, general improvement (decrease in or disappearance of pain, restoration of appetite, and gain in body weight) was evident in about 16 patients with mammary carcinoma (75%), and local improvement in the neoplastic lesion was found in about 10 patients with mammary carcinoma (45%). These improvements persisted on the average for 6 months, but no longer than 12 months.

Destruction of the pituitary body with Y^{90} seemed to have affected the malignant growth, other than carcinoma of the breast, in only 2 of 15 patients (14%). However, this procedure brought about subjective improvement in a patient with adenoma of the pituitary. The attempt to reduce the thyrotropic activity of the pituitary with Y^{90} in 2 patients with exophthalmos was crowned with such remarkable success that the authors recommended the procedure for refractory cases of the disease. Clinical improvement in one patient still persisted a year after the treatment with Y^{90}. The opinion of the authors is that a discriminating application of the interstitial irradiation of the pituitary body with Y^{90} is a useful procedure for the management of certain types of neoplasms, particularly those at the initial phase of growth, which are related to the pituitary body.

ANESTHESIA

Anesthetic Problems in Cardiopulmonary Bypass for Open Heart Surgery: Experiences with 200 Patients. A. S. Keats, Y. Kurosu, J. Telford and D. A. Cooley. Anesthesiology 19:501-514 (July-Aug.) 1958 [Philadelphia].

The authors review anesthetic problems in the management of 200 patients who underwent cardiopulmonary bypass for intracardiac surgery. This group included 102 patients with ventricular septal defects, 28 with atrial septal defects, and 18 with tetralogy of Fallot; the others had such defects as atrioventricularis communis, transposition of the great vessels, and various forms of aortic or pulmonary stenosis. The authors used bubble-type oxygenators with low-flow perfusion in all their patients. The perfusion rate for each kilogram of body weight per minute was 35 cc. for adults, 40 to 50 cc. for children, and 50 cc. for infants. In the first 60 patients, coronary artery perfusion was permitted continuously during bypass, and on rare occasions coronary blood was returned to the pump. In the next 73 patients, asystole of the heart during perfusion was accomplished by cross clamping the aorta and injecting potassium citrate solution into the proximal part of the aorta and coronary system. In the last 67 patients the proximal part of the aorta was clamped without chemical arrest of the heart and the clamp released intermittently to allow coronary blood flow.

Serious arrhythmias from extensive manipulations of the heart were minimized by the use of light general anesthesia. Hyperventilation was deliberately used to provide a high-tension tissue store of oxygen by nitrogen washout and a respiratory alkalosis which compensated for the mild metabolic acidosis produced by low-flow perfusion. It was not found necessary to add any anesthetic agent or carbon dioxide to the oxygenator during cardiopulmonary bypass. Curare was administered prior to bypass to eliminate striated muscle contraction and to minimize metabolic acidosis. Its use with complete collapse of the lungs provided ideal operating conditions and had no deleterious effects. For blood replacement, fresh citrated blood was used for transfusion throughout the procedure in small children; in larger children and adults, stored citrated blood was used before bypass and fresh blood after bypass. Most patients were hypothermic after bypass; these patients were slowly rewarmed in the recovery room by a heating blanket. Ventricular fibrillation occurred in 33 patients during or immediately after bypass. It was most frequent after the use of potassium citrate to produce cardiac asystole. Twenty-one of the 33 patients with ventricular fibrillation were successfully defibrillated. A significant heart block occurred in 11 patients, presumably from sutures placed through the conduction bundle. If an adequate blood pressure could be maintained at the slow heart rate, usually no ill-effects ensued. The use of a mechanical pacemaker was not successful. A tracheotomy was performed at the end of the operation when large amounts of blood were removed through the endotracheal tube. Usually bloody secretions in the trachea were the results of pulmonary edema, but at times trauma from extensive retraction of the lungs was a causative factor. Tracheotomy facilitated removal of secretions and provided proper ventilation of the lungs.

There were 45 deaths in this series of 200 patients, a hospital mortality of 22.5%. Nineteen of the deaths occurred in the 40 infants under 1 year of age. This high death rate was chiefly the result of the severe heart disease. Over 90% of the deaths occurred in either the operating or the recovery rooms or within the first 3 days after operation.

PHYSIOLOGY

The Gastroesophageal Mechanism: II. Further Experimental Studies in the Dog. J. H. Meiss, J. H. Grindlay and F. H. Ellis Jr. J. Thoracic Surg. 36: 156-165 (Aug.) 1958 [St. Louis].

In the first of 4 groups of mongrel dogs studied in an attempt to determine the nature of the mechanism responsible for gastroesophageal continence, the esophagogastric junction was removed and the esophagogastric anastomosis made in several ways. In the second group the acute esophagogastric angle was eliminated by resection of the fundus or by division of the stomach below the junction and subsequent anastomosis of the upper rim to the fundus. The animals in group 3 underwent formation of a partial thoracic stomach. The mucosal rosette was eliminated in animals of group 4, in addition to the elimination of the acute esophagogastric angle and the diaphragmatic pinchcock. Esophagitis developed in all the animals in the first group, indicating that an acute esophagogastric angle and the diaphragmatic pinchcock cannot prevent esophagitis after removal of the esophagogastric junction. Esophagitis did not develop in any of the animals in the second group; therefore, an acute esophagogastric angle is not necessary to prevent reflux esophagitis in dogs. The results of studies in the third group of dogs revealed that the diaphragmatic pinchcock is not an essential mechanism for the prevention of reflux esophagitis. Esophagitis did not develop in any of the dogs in the fourth group in whom the mucosal rosette was eliminated, in addition to the elimination of the acute esophagogastric angle and the diaphragmatic pinchcock. This left the presence of an intrinsic sphincter mechanism in the region of the esophagogastric junction as the only possible mechanism which could have prevented esophagitis.

PUBLIC HEALTH

Epidemic Virus Meningitis Due to ECHO 9 Virus in Newfoundland. J. W. Davies, A. McDermott and D. Severs. Canad. M. A. J. 79:162-167 (Aug. 1) 1958 [Toronto].

In recent years there have been numerous reports of epidemic meningitis due to virus infection in which a rubelliform type of rash has been present in a large percentage of the cases. During 1957 a total of 44 patients with aseptic meningitis of this type were admitted to the Isolation Hospital in St. John's, Nfld., slightly more than one-third of the total admissions occurring during the month of August. The highest incidence (40.9%) occurred in the 5-to-9-year age group, the disease affecting the males predominantly in a ratio of 1.5 males to 1 female. In the 20-and-over age group this ratio was reversed, females predominating 5 to 1. A pronounced feature of this epidemic was the high attack rate—the secondary attack rate was slightly in excess of 50%—among family contacts, nearly one-third of the adults in contact with a patient at home being affected. The high proportion of positive viral isolations from throat washings, as compared with fecal isolations, suggests that droplet infection is the more important mode of spread.

Inasmuch as poliomyelitis and Coxsackie virus infections were absent in the population at this time, the clinical picture of enteric cytopathogenic human orphan (ECHO), type 9, virus infection appeared to conform with the following pattern: (1) history of biphasic illness, (2) highly contagious type of illness with a high attack rate among families, (3) typical exanthem, (4) two-phase temperature plot, (5) moderate pleocytosis and normal chemical findings in spinal fluid, and (6) leukopenia with relative lymphocytosis. Pathological material from 36 patients suspected of virus infection which was submitted for examination yielded virus on human amnion or monkey-kidney cell tissue culture in 17 cases. The virus was isolated from 13 of 28 specimens of spinal fluid, from 12 of 34 throat cultures, and from 5 of 28 rectal swabs or stools. The illness commenced generally with prodromal symptoms of anorexia, fever, chills, generalized muscular aches and pains, drowsiness, and headache.

Observations on the Potency and Safety of Poliomyelitis Vaccine (Salk Type) Currently Used. K. Sunada, R. K. Gerloff, D. Brock and others. A. M. A. J. Dis. Child. 96:125-130 (Aug.) 1958 [Chicago].

A total of 605 children, ranging in age from 5 to 15 years and residing in widely separated areas of Idaho, were given poliomyelitis vaccine, 143 uninoculated children serving as control subjects. Each child received 3 intramuscular doses; the first 2 injections were given in the spring and early summer of 1956, the second injection 1 month after the first, and the third injection was given 7 months after the second. The injection of the lots of vaccine used in this study was not accompanied by any illness suggestive of poliomyelitis in either the vaccinated children or their contacts. In the control children, natural infection and a concommitant increase in the antibody titer from 1:8 to 1:64 were evident in only one child in the early stages of the experiment and were impossible to calculate at a later date as many of the controls requested vaccination.

When type 1 antibody was present alone in the preinjection serum, type 2 antibody appeared in 94% of the children after the first injection. A similar response (72% conversion to type 2) was forthcoming when type 3 antibody was present in the preinjection serum. When antibodies against types 1 and 2 were present, type 3 antibody appeared in a higher percentage of children (50%) than when types 1 and 2 were present singly (13 to 22%). These differences still persisted after inoculation (86% as compared with 51 to 67%). In the event that antibody types 1 and 3 or types 2 and 3 were present in the preinjection serum, all 3 types generally appeared after only one injection. After one dose of vaccine, type 2 antibody appeared in the serums of 20% of those children who did not demonstrate antibodies in the serums prior to vaccination, types 1 and 3 being present in minimal amounts (7 and 4%). After 3 injections, 73 and 29% of the children showed antibody types 1 and 3, and practically all (99%) had type 2. While type 2 antibody resulting from natural exposure had a marked influence on the development of heterotype antibody after vaccination, type 2 antibody resulting solely from vaccination did not exert a comparable influence. The difference in the heterotypical response which did occur in children possessing type 2 antibody, as compared with those lacking this antibody, reflected in all probability not a true cross antigenic effect but rather a difference in the innate ability of the individual child to produce said antibodies.

In general, the data revealed that the 3 components of the poliomyelitis vaccine acted as specific entities and that they had little, if any, antigenic relationship to one another, the final development of an antibody to any one type of antigen resulting from a cumulative effect of that type of antigen rather than from a cross effect between types. A further dose given 3 months after the preceding one to 39 children lacking one or more antibody types after the customary 3-dose injection regimen resulted in all 12, who had possessed antibodies against one type of virus prior to the first injection of vaccine, becoming "triple positive," except for one child who lacked type 3 antibody. Of the remaining 27 children who had been "triple negative" prior to vaccination, 85, 100, and 56% possessed antibody types 1, 2, and 3, respectively, after the 4th dose.

The Epidemiology of Aseptic Meningitis and Related Nonspecific Disease in Connecticut, 1957: Virological and Clinical Studies. L. Dubin and D. M. Horstmann. Yale J. Biol. & Med. 30:429-441 (June) 1958 [New Haven, Conn.].

During the summer of 1957, virological and serologic investigations were carried out on specimens from 56 patients in Connecticut in whom nonparalytic poliomyelitis, aseptic meningitis, or nonspecific febrile illness had been diagnosed, and from 1 patient with paralytic poliomyelitis. It was possible to make a specific etiological diagnosis on 33 of the patients. The absence of poliomyelitis virus was striking. Only 2 isolations of the type 1 virus were made. This experience is in line with what occurred in the rest of the United States and is markedly different from the experience of the preceding years.

ECHO and Coxsackie viruses played a definite role as the etiological agents of aseptic meningitis and associated nonspecific febrile disease in various parts of Connecticut during the summer of 1957. In addition, agents not belonging to any of the known enterovirus types were also active in the same area at the same time and were associated with clinical syndromes similar to those produced by ECHO and Coxsackie viruses. ECHO virus type 9 was the most commonly isolated enterovirus, a finding which differs markedly from the Connecticut experience of the previous 2 years. An unusual clinical feature of the cases studied was the presence of a rubella-like rash, associated not only with ECHO 9 virus infection, but with Coxsackie A-9 and with unidentified agents as well. The rash was similar in character and distribution in the 3 etiological groups.

clinical experience. The result is a concise, practical book from which much theoretical and questionable material has been omitted. The subjects are logically presented in nine separate sections and an appendix in the following order: normal and abnormal pregnancy, normal and abnormal labor, the puerperium, operative obstetrics, the newborn baby, radiology, and maternal and fetal mortality. Informative and skillfully executed line drawings profusely illustrate all the subjects. The book includes a great deal of useful information concerning patients and benefits of state insurance and other matters of interest chiefly to the English practitioner. There are some differences in the accepted practices in Great Britain and those current in the United States, but fundamental principles are the same. Natural delivery is recommended in all cases unless operative procedures are indicated. Most obstetricians in the United States prefer to terminate labor by an episiotomy and outlet forceps after the head begins to bulge the perineum. An intelligent approach to abdominal delivery and the management of most complications is presented. The use of the external version to correct breech presentation in late pregnancy carried out with the patient under anesthesia, however, is questionable. The induction of labor in patients who are two weeks post-term and have babies of 6 lb. (2,721 kg.) or more in weight is not uncommon in Britain but is rarely practiced in the United States. It was a real surprise to read that paste can be introduced into the uterus as a method of therapeutic abortion. The format of the book, an appropriate quotation from Shakespeare which heads each chapter, an interesting cover, and legible printing add much to its appeal. It can be read with profit by American physicians as well as those in Great Britain.

Industrial Hygiene and Toxicology. Volume I: General Principles. Frank A. Patty, editor. [To be in 3 volumes.] Second edition. Cloth. $17.50. Pp. 830, with illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88/90 Chancery Lane, London, W. C. 2, England, 1958.

The revised edition of this treatise on industrial hygiene and toxicology has been expanded to three volumes. Volume 1 deals with general principles and contains chapters by the editor and 17 contributors. To keep abreast with the extension of industrial hygiene into new fields, chapters on human engineering and industrial safety, industrial sanitation, air pollution, industrial noise and the conservation of hearing, lighting for seeing, and heat control in the hot industries were added. Extensive revisions were made in the chapters on industrial hygiene records and reports, the pulmonary dust diseases, radiant energy, and ventilation. The remaining chapters required less extensive revision. This volume contains a wealth of useful and authoritative information in the various specialties. Many pertinent references are given to the original literature. The revised edition more than ever is an outstanding reference source and textbook for students and practitioners in the field of industrial hygiene and toxicology.

A Symposium on Non-Toxaemic Hypertension in Pregnancy. Edited by Norman F. Morris, M.D., M.B., B.S., Reader in Obstetrics and Gynaecology, University of London, London, and J. C. McClure Browne, B.Sc., M.B., B.S., Professor of Obstetrics and Gynaecology, University of London. Cloth. $8.50. Pp. 243, with 78 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W.1, England, 1958.

This symposium was held in London in July, 1957. The topics discussed included genetic studies of hypertension in pregnancy, the course of pregnancy complicated by essential hypertension, renal hypertension and pregnancy, pheochromocytoma, coarctation of the aorta and pregnancy, and the recognition and management of these conditions. The subject is presented as well as could be expected, considering the gross inadequacy of the existing scientific data. One is impressed by how far the obstetric field is behind in its understanding of hypertension. Still more discouraging is the fact that so little is being done to correct this inadequacy. A few of the more interesting points under discussion centered around the controversy as to whether a distinction can be made between a normal and hypertensive arterial pressure level. It is the old problem of trying to equate a disease with a single clinical sign. McMichael clearly disagrees with Pickering, who is a proponent of the statistical view. Duff concludes that the increased peripheral resistance in essential hypertension does not involve the upper extremities and does not depend on structural vascular narrowing or on overactivity of the sympathetic nerves, but these are rather large conclusions for the evidence submitted. The high incidence of gestoses in England is surprising. It is not made clear by Milne how mecamylamine differs completely from the quarternary ammonium blocking agents, although his vignette of the pharmacology of antihypertensive drugs is excellent. Theobald believes that weekly antenatal care is associated with a sharp fall in the incidence of eclampsia. It is hard to believe that the veratrum used in the good old days at Queen Charlotte's really did as much good as Mr. Bourne suggests. Any symposium on hypertension is the better for having Dr. Robert Platt in attendance. This one was no exception. Max Rosenheim, in his concluding remarks, hopes for another similar symposium. This would be worthwhile only if fresh data were forthcoming to arouse and sustain both interest and purpose.

BOOK REVIEWS

Principles of Internal Medicine. Editors: T. R. Harrison and others. Third edition. Cloth. $18.50. Pp. 1782; 57, with 211 illustrations. Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E. C. 4, England; 253 Spadina Rd., Toronto 4, Canada, 1958.

This book is becoming one of the standard textbooks in its field. The necessity for a third edition within eight years is evidence of its reception. As the book has proceeded through these editions, additional editors have been added to achieve uniformity of approach. For the new edition, the unconventional arrangement, as compared with other books in the field, has been retained but modified. New sections have been added by experts in their fields. The list of contributors is extensive and impressive. It encompasses most of the major medical schools in the United States and a few from abroad. The book begins with a short section on the approach to the patient by the physician. Part 2, "Cardinal Manifestations of Disease," takes up individual symptoms or signs from a broad medical point of view. The section on disorders of nervous function has been expanded and strengthened. Part 3 considers biological phenomena, such as inheritance, aging, neoplasia, and metabolic pathways, and the principals of electrophysiology. Part 4 systematically discusses metabolic and endocrine disorders, part 5, those due to physical and chemical agents, and part 6, those due to biological agents—the infectious diseases. Part 7 contains a short discussion of allergic diseases and drug reactions; Part 8 takes up the various organ systems. The last part is a general discussion of the care of the patient and covers principles of nutrition, sedation, and transfusion, as well as production of disorders by the physician.

Most of the sections are excellently written. The format, with narrow margins and two columns on a page, is pleasing to the eye and can be easily read. Scattered through the book are tables of particular tests comparing normal values with those found in specific diseases, as well as tables for comparison of effects of lesions. At the end in an appendix are tables of laboratory values of clinical importance. Six excellent color plates of patients and lesions are scattered through the book. A small number of clear illustrative diagrams is also included. The references at the end of each section are carefully selected, are few in number, and include articles through 1956. This book should serve well as a textbook for medical students and, for general practitioners and internists in practice, as a reference work.

Mirror to Physiology: A Self-Survey of Physiological Science. By R. W. Gerard, M.D., Ph.D., Sc.D., Professor of Neurophysiology in Psychiatry and Physiology, University of Michigan, Ann Arbor. Cloth. Pp. 372, with illustrations. American Physiological Society, 9650 Wisconsin Ave., Washington 14, D. C., 1958.

This book gives the results of a survey undertaken by the American Physiological Society in an effort to define physiology, to discover what kind of people are now classified as physiologists, and to consider how to interest an adequate proportion of the nation's manpower in cultivating this important field of science. In the foreword, W. O. Fenn expresses the belief that, if there is any serious deficiency in physiology at present, it is probably in the recruitment of personnel of high competence. Much space is devoted to the technical problems of the survey itself, and this should be instructive to other organizations planning similar ventures. Quantitative data were obtained as to the activities, employment, and income of physiologists, their occupational motivations, satisfaction, and mobility, and their research activities and programs. There are chapters on research facilities and support, publications and societies, professional training and recruitment, and public relations and education. A closing chapter interprets the results and makes recommendations. It is followed by an appendix and an index. This book represents an earnest and costly effort to define and count some extremely elusive entities. It is hard to say how successful this effort has been, but its importance is undeniable. This survey of one aspect of our scientific manpower problem deserves the attention of everyone who may be in a position to direct the engaging of personnel or the application of funds for teaching and research.

A Modern Practice of Obstetrics. By D. M. Stern, M.A., M.B., B.Ch., and C. W. F. Burnett, M.D., F.R.C.S., F.R.C.O.G. Second edition. Cloth. $9. Pp. 258, with 141 illustrations, line drawings by Susan M. Robinson. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; Baillère, Tindall & Cox, 7 & 8 Henrietta St., Covent Garden, London, W. C. 2, England, 1958.

This new edition of an English textbook of obstetrics was written for candidates for examination and practitioners of obstetrics. The authors indicate that, where there have been differences of opinion as to procedure, they have relied on their own

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

clinical experience. The result is a concise, practical book from which much theoretical and questionable material has been omitted. The subjects are logically presented in nine separate sections and an appendix in the following order: normal and abnormal pregnancy, normal and abnormal labor, the puerperium, operative obstetrics, the newborn baby, radiology, and maternal and fetal mortality. Informative and skillfully executed line drawings profusely illustrate all the subjects. The book includes a great deal of useful information concerning patients and benefits of state insurance and other matters of interest chiefly to the English practitioner. There are some differences in the accepted practices in Great Britain and those current in the United States, but fundamental principles are the same. Natural delivery is recommended in all cases unless operative procedures are indicated. Most obstetricians in the United States prefer to terminate labor by an episiotomy and outlet forceps after the head begins to bulge the perineum. An intelligent approach to abdominal delivery and the management of most complications is presented. The use of the external version to correct breech presentation in late pregnancy carried out with the patient under anesthesia, however, is questionable. The induction of labor in patients who are two weeks post-term and have babies of 6 lb. (2,721 kg.) or more in weight is not uncommon in Britain but is rarely practiced in the United States. It was a real surprise to read that paste can be introduced into the uterus as a method of therapeutic abortion. The format of the book, an appropriate quotation from Shakespeare which heads each chapter, an interesting cover, and legible printing add much to its appeal. It can be read with profit by American physicians as well as those in Great Britain.

Industrial Hygiene and Toxicology. Volume I: General Principles. Frank A. Patty, editor. [To be in 3 volumes.] Second edition. Cloth. $17.50. Pp. 830, with illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88/90 Chancery Lane, London, W. C. 2, England, 1958.

The revised edition of this treatise on industrial hygiene and toxicology has been expanded to three volumes. Volume 1 deals with general principles and contains chapters by the editor and 17 contributors. To keep abreast with the extension of industrial hygiene into new fields, chapters on human engineering and industrial safety, industrial sanitation, air pollution, industrial noise and the conservation of hearing, lighting for seeing, and heat control in the hot industries were added. Extensive revisions were made in the chapters on industrial hygiene records and reports, the pulmonary dust diseases, radiant energy, and ventilation. The remaining chapters required less extensive revision. This volume contains a wealth of useful and authoritative information in the various specialties. Many pertinent references are given to the original literature. The revised edition more than ever is an outstanding reference source and textbook for students and practitioners in the field of industrial hygiene and toxicology.

A Symposium on Non-Toxaemic Hypertension in Pregnancy. Edited by Norman F. Morris, M.D., M.B., B.S., Reader in Obstetrics and Gynaecology, University of London, London, and J. C. McClure Browne, B.Sc., M.B., B.S., Professor of Obstetrics and Gynaecology, University of London. Cloth. $8.50. Pp. 243, with 78 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W.1, England, 1958.

This symposium was held in London in July, 1957. The topics discussed included genetic studies of hypertension in pregnancy, the course of pregnancy complicated by essential hypertension, renal hypertension and pregnancy, pheochromocytoma, coarctation of the aorta and pregnancy, and the recognition and management of these conditions. The subject is presented as well as could be expected, considering the gross inadequacy of the existing scientific data. One is impressed by how far the obstetric field is behind in its understanding of hypertension. Still more discouraging is the fact that so little is being done to correct this inadequacy. A few of the more interesting points under discussion centered around the controversy as to whether a distinction can be made between a normal and hypertensive arterial pressure level. It is the old problem of trying to equate a disease with a single clinical sign. McMichael clearly disagrees with Pickering, who is a proponent of the statistical view. Duff concludes that the increased peripheral resistance in essential hypertension does not involve the upper extremities and does not depend on structural vascular narrowing or on overactivity of the sympathetic nerves, but these are rather large conclusions for the evidence submitted. The high incidence of gestoses in England is surprising. It is not made clear by Milne how mecamylamine differs completely from the quarternary ammonium blocking agents, although his vignette of the pharmacology of antihypertensive drugs is excellent. Theobald believes that weekly antenatal care is associated with a sharp fall in the incidence of eclampsia. It is hard to believe that the veratrum used in the good old days at Queen Charlotte's really did as much good as Mr. Bourne suggests. Any symposium on hypertension is the better for having Dr. Robert Platt in attendance. This one was no exception. Max Rosenheim, in his concluding remarks, hopes for another similar symposium. This would be worthwhile only if fresh data were forthcoming to arouse and sustain both interest and purpose.

QUESTIONS AND ANSWERS

PROGESTERONE FOR OVARIAN CYSTS

To the Editor:—*Please comment on the rationale of using oral progesterone therapy for small painful cysts of the ovaries. These cysts frequently occur, cause a lot of abdominal discomfort, and sometimes alter the menstrual cycle. Are there any references to this subject in the literature? Would treatment with cyclic estrogens help the condition? I am now giving progesterone orally during the last half of the menstrual cycle. Could such treatment have a salutary effect?*

Samuel S. Lambeth, M.D., Maryville, Tenn.

Answer.—The administration of progesterone produces a progestin effect on estrogen-primed endometrium and a suppressive effect on luteinizing hormone from the anterior pituitary. If the etiology of the small painful cysts of the ovary is endometriosis, the administration of progesterone should aggravate, rather than improve, the condition.

In most instances multiple small cysts of the ovaries represent a number of unruptured graafian follicles secondary to either an oophoritis which mechanically prevents ovulation or a functional disturbance of the pituitary-ovarian cortex axis. Clinically, this is most often manifested by altered menstrual cycles. Pituitary gonadotropin suppression by large doses of estrogen in regulated cycles sometimes produces symptomatic relief. Several aspects of the effects of endocrine therapy are discussed in the *American Journal of Obstetrics and Gynecology* (vol. 75, Jan., Feb., 1958).

CHEESE AND SERUM CHOLESTEROL LEVEL

To the Editor:—*Would the eating of 1.5 lb. of cheese a week—not cream cheese—tend to bring about an excess accumulation of cholesterol in a patient's system? What suggestions should be made to such a patient?*

M.D., North Carolina.

Answer.—There is no evidence to implicate the ingestion of 1.5 lb. of cheese a week with the development of an excess amount of cholesterol in the blood. There are so many variables concerned with the amount of cholesterol present in the body that one cannot blame any one dietary item. At the present time, there is no good evidence indicating that a high blood cholesterol level is a sign that one will have a heart attack. Apparently, there is a statistical relationship between high blood cholesterol levels and heart attacks, but, as yet, there has been shown no cause and effect relationship. The Food and Nutrition Board of the National Research Council has recently published a pamphlet in which this conclusion is made: "Evidence to support the concept that high levels of plasma cholesterol, per se, in man are atherogenic is far from conclusive. Circumstantial evidence, however, indicates that the kind, or amount, of dietary fat is in some way related to some stages of atherosclerosis in man. A reduction in intake of the more saturated fats in the diet may ultimately prove desirable for health but is not yet mandated by currently available evidence."

VENOUS SPIDERS

To the Editor:—*Please comment on the small, superficial, radiating types of varicosities so often seen on the anterior and posterior surfaces of the thighs of young women. This condition is encountered from time to time in individuals who are concerned only because of the cosmetic defect which it presents. Seemingly there is no relationship to the tendency towards varicosities in the lower extremities because it is so often seen in the absence of this finding in a great number of patients. Treatment by injection of sodium morrhuate with tiny (30-gauge) needles has been suggested. I have also tried electrolysis of some of these tiny vesicles, but the results have been equivocal, and the treatment is also painful. Should a young patient with such varicosities continue dancing and drill team activities?*

Harold L. Boyer, M.D., Las Vegas, Nev.

Answer.—Venous spiders appear on the thighs of women independently of varicose veins. Their mode of production is obscure, although a hormonal influence is suggested by their accelerated appearance or growth at puberty, during pregnancy, and after menopause. They frequently radiate from a small central pool. Venous spiders do not cause pain or swelling, they will not ulcerate, and they do seem to run in families. Occasionally, without any obvious injury, they rupture subcutaneously causing a small hematoma and much fear of blood clot.

There seems no reason to prohibit dancing or any athletic activity. Injection of the central pool with a few drops of mild sclerosing solution, with use of a magnifying glass, has been done. The spiders,

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

however, will appear somewhere else. Cautery is inadvisable and leaves a more unsightly scar than the original lesion. Parents, of course, are anxious to prevent any spread of such lesions. Nothing is known to this consultant which would effectively prevent new crops of spiders. Repeated pregnancies definitely aggravate them. Skin preparations may effectively cover them and relieve some of the anxiety relating to their cosmetic appearance.

PROPTOSIS

To THE EDITOR:—*A 41-year-old woman stated that a fluorescent tube (20-watt) exploded in front of her right eye and that powder and glass entered this eye. Four days after the accident, both lids of the right eye were swollen; they remained so, and about two months after the accident bulging of the right eye began to develop. Examination revealed a proptosis of the right eye of about 5 mm., compared to the left. External examination showed bulging of the right eye; conjunctival hyperemia and chemosis of moderate degree; pupil equal, regular, and reactive to light and accommodation; and no limitation of ocular movements in all directions. Findings in fundoscopy were negative. Her vision is 20/20 in each eye. Results of x-ray of the orbits, including optic canals, were negative. Findings in all tests for throid function were also negative. The condition appeared clinically to be pseudogranuloma of the orbit. Please give information as to whether the chemical contents of the fluorescent bulb, as described below, can cause this type of condition: argon gas, very small amount under 3 mm. of pressure; liquid mercury, 50 mg.; fluorescent powder on wall, 5 Gm. of calcium halo phosphate (red), zinc silicate (green), and magnesium tungstate (blue) (although all lamps would contain all of these, the proportion would change depending on the color of the particular lamp); and emission coating at each end of filament, 12 mg. of calcium carbonate, barium carbonate, and strontium carbonate.* *M.D., New Jersey.*

ANSWER.—The mention in the query of a "pseudogranuloma" at once suggests the action of beryllium. Not since 1949 has beryllium entered the standard brands of fluorescent tubes for illumination. There remains the unlikely prospect that an old tube might have been involved. The somewhat precise chemical analysis presumably would have detected beryllium if any had been present. Of the mentioned phosphors, none is known to be capable of inducing the significant findings indicated, notably the proptosis. Several are capable of inducing temporary acute irritation such as was observed. The action of tungsten on the human body, including that on the eye, has not been well explored. There remains the remote possibility that this one substance might be more active than is now established. In general, there is no known reason to attribute the proptosis to the action of the chemicals noted and under the circumstances set forth.

NYLON SENSITIVITY

To THE EDITOR:—*A patient develops a contact dermatitis every time she wears nylon stockings or other pieces of clothing containing nylon. Is there any treatment other than elimination of nylon clothing? Can an antigen be made for injection? If so, where can it be obtained?*

Frank D. Levy, M.D., Philadelphia.

ANSWER.—There is no real effective prophylactic treatment for contact dermatitis due to wearing apparel such as nylon, apart from avoidance. Although commercial allergy laboratories prepare extracts of nylon for skin testing and presumably for treatment, desensitization with this material is questionable and has not met with great success. Before a recommendation is made that all types of nylon be discarded, however, a patch test should be performed in order to determine whether it is the nylon, the dye, or other chemicals used in the processing of the material which is responsible for the dermatitis. The technique of the patch test is described in textbooks on allergy and dermatology. Briefly, it consists of the application of a small piece of the suspected material on a convenient portion of the skin of the patient to be tested, covering with an occlusive dressing, and leaving the material in place for at least 48 hours. A positive skin test will be indicated by a dermatitis at the site of contact. Occasionally the reaction may be delayed. Therefore, it is wise to observe the site where the nylon was placed for several days after removal of the patch. Various colors and types of nylon material and nylon thread should be tested individually in order to determine which type, if any, can be used.

TREATMENT OF MUMPS IN ADULTS

To THE EDITOR:—*Please outline therapy for mumps in a 30-year-old woman. Are antibiotics indicated and will they prevent encephalitis or pancreatitis?* *MD., Illinois.*

ANSWER.—The treatment of a 30-year-old woman with mumps is symptomatic and supportive. Such general measures include rest and relief of pain with analgesics if necessary. Local application of heat or cold may help. There are no significant dietary measures. Headache and symptoms due to increased cerebrospinal fluid pressure occurring in encephalitis due to mumps may be relieved by reducing the pressure toward normal by lumbar drainage. Antibiotics are not indicated, nor will they prevent any of the complications of mumps, including encephalitis and pancreatitis. Gamma globulin prepared from blood collected from patients in the convalescent stage of mumps has been shown to decrease the incidence of orchitis in adult males when given 24 hours or less after the onset of parotitis. Gamma globulin not specifically obtained from patients in convalescence from mumps did not have this effect. Definitive knowledge of the ability gamma globulin obtained from persons in convalescence from mumps to lower the incidence of involvement of the central nervous system or glands other than the parotid in females is not available. The value of steroid hormones for preventing or treating complications of mumps is not established.

PIGMENTATION OF THE GUMS

To the Editor:—*A 16-year-old boy has marked, dark pigmentation of the gums, such as is ordinarily seen in Addison's disease. However, there are no symptoms of this condition. His 17-ketosteroid level is within normal range, and a 24-hour excretion was doubled with the use of ACTH. There is no evidence of heavy metal poisoning. Laboratory studies, such as we are able to do, are within normal range. What other conditions should one consider with increased gum pigmentation in a boy of this age?*

Howard P. Holt, M.D., Yakima, Wash.

Answer.—Pigmentation of the attached gingival tissues, and at times the oral mucosa and lips, will develop in any dark-complexioned patient. This physiological pigmentation usually develops fully during the second decade. This pigmentation is the result of the deposition of increased amounts of melanin. Oral mucosal pigmentation may also be found in patients with intestinal polyposis. It may be present in the familial form of polyostotic fibrous dysplasia (Albright's disease). The administration of certain drugs, for example, quinacrine hydrochloride, may be associated with a yellowish pigmentation of the oral tissues. In the absence of any clinical or roentgenologic findings suggestive of intestinal polyposis or polyostotic fibrous dysplasia, it is most likely that the gingival pigmentation is physiological.

VITAMIN A INTOXICATION

To the Editor:—*Please give advice on what danger, if any, there is in the use of vitamin A. A recent article in an eye, ear, nose, and throat journal gave the impression that vitamin A intoxication could cause intracranial changes.*

M.D., Michigan.

Answer.—Apparently, the body can tolerate quantities of vitamin A 100 times greater than the daily physiological requirement, but there is a definite possibility of harm from the prolonged ingestion of vitamin A in excess of 50,000 I. U. daily. Chronic vitamin A intoxication occurs more frequently in children than in adults. Depending on the severity of the intoxication, the symptoms appearing in children older than 1 year include anorexia, loss of weight, extreme irritability, fretfulness and pruritus, seborrhea-like cutaneous eruptions, fissuring at the corners of the mouth, and cracking and bleeding of the lips. Later symptoms often include hepatomegaly, hydrocephaly, alopecia, painful swellings over the long bones with bone and joint pains and bone tenderness, hyperostosis, deep, hard, and tender swellings in the extremities, cortical thickening in tubular bones, and elevated serum vitamin A levels. Vitamin A intoxication in adults presents symptoms similar to those of hypervitaminosis A in children but usually milder. Structural bone changes are not likely to occur, and bone and joint pains are not so severe. Menstrual alterations, exophthalmos, and pigmentation of the skin are often found. Transitory hydrocephaly is a prominent finding when toxicity is acute.

NUMMULAR ECZEMA

To the Editor:—*A 19-month-old boy has suffered since the age of 8 months from a dermatosis classified as nummular eczema. The lesions are localized on both cheeks, shin, extensor surfaces of extremities, gluteal area, and abdomen. These well defined, reddish brown plaques tend to ooze and to form brownish scabs. There is a slight scaling, no itching, and some infiltration. Fungus studies have not been done. Various modes of treatment have been tried, including that with coal tar and other tar preparations, hydrocortisone cream and lotion, immune globulin, and antibiotics according to culture and sensitivity tests from the skin and from a concomitant chronic tonsillitis. The dermatosis is improved, with healing in the center of the plaques and less exudation; however, it is far from "cured." A few years ago a report appeared of treatment of nummular eczema with vitamin A given parenterally. Has this treatment proved successful? How is it done? Please give other suggestions as to the management of this case.*

M.D., Maryland.

Answer.—Nummular eczema is seen in children, but less often than in adults. In both, it is often resistant to treatment. Vitamin A therapy has been suggested by some, but its value in this condition seems limited. When vitamin A is used, parenteral therapy is usually not required. The danger of vitamin A intoxication should be remembered, especially in infants. In order to guard against this, there should be definite rest periods when vitamin A therapy is discontinued. From the morphologic description given, the diagnosis of infantile eczema should be considered.

BILIARY CIRRHOSIS AND COLITIS

To the Editor:—*A 28-year-old woman with massive ascites, abnormal liver function tests, and characteristic x-ray and proctoscopic findings of extensive ulcerative colitis involving all segments of the colon has been seen for the first time. There was 8,000 cc. of clear fluid removed from the abdomen for symptomatic relief. Have there been any recent experiences, in this uncommon situation, with respect to (1) efficacy of steroid therapy and (2) removal of the colon, presupposing that it is the site of the basic disorder and that the hepatic dysfunction is secondary?*

Robert C. Lawson, M.D., Oklahoma City.

Answer.—Biliary cirrhosis is not an uncommon late complication of long-standing ulcerative colitis. It would be of interest to know how long this patient has had the colitis, presupposing that the condition is of this type. In the absence of any evidence of malignant disease, however, this is the likely complication. Surgery at this stage is carried out with considerable risk, and it is not likely to revert the process in the liver. Steroid therapy has not proved to be of particular value in these cases.

CALCIUM AND ARTERIOSCLEROSIS

To the Editor:—*A patient with an ulcer says he has read that diets containing large amounts of milk predispose to arteriosclerosis. He blames this on the calcium content, not the fat content. Is there any substantiation to this?*

Robert M. Michels, M.D., Flushing, Mich.

Answer.—This consultant is unaware of any evidence implicating calcium in the development of arteriosclerosis. Some workers believe that an excessive consumption of animal fat, of which milk fat is one example, does have a causal relationship with atherosclerosis. However, this relationship has not yet been proved.

DIGITALIS AND NITROGLYCERIN IN MYOCARDIAL INFARCTION

To the Editor:—*Are digitalis and nitroglycerin indicated in treatment of acute myocardial infarction?*

Reynaldo E. Laureano, M.D., Baltimore.

Answer.—The use of nitroglycerin is not indicated in cases of known acute myocardial infarction. There is no reason to suppose that this drug will relieve the ischemia produced by an occluded vessel. In addition to this, nitroglycerin produces a fall in blood pressure which is not desirable in the shock state that may accompany myocardial infarction. Digitalis is not indicated for the treatment of acute myocardial infarction. If there is ventricular hyperirritability shown by frequent ectopic ventricular systoles, the use of digitalis is hazardous. However, if there is acute congestive heart failure associated with the infarction, digitalis should be used as in any case of congestive heart failure. Here digitalis is used in the treatment of the congestive failure, not in the treatment of the infarct. There is some evidence that digitalis may have an adverse effect on the coronary flow, but, in the presence of congestive failure, the hazard associated with the failure is greater than the hazard of a possible reduction in the coronary flow.

PRURITUS WITH CIRRHOSIS

To the Editor:—*A patient with hypertrophic (Hanot's) cirrhosis has a markedly elevated cholesterol level of 2,000 mg.%, an elevated bilirubin level of 10 mg.%, and a main complaint of severe pruritus. She has not responded to the usual therapeutic procedures and medication. Please advise treatment for both the primary disease and the pruritus.*

Roy T. Pearson, M.D., Spokane, Wash.

Answer.—There is no specific treatment for hypertrophic cirrhosis. It is desirable to maintain adequate nutrition, and it is important to provide extra amounts of the fat soluble vitamins, since these are poorly absorbed in this condition. Medical treatment of the pruritus is usually rather ineffective. Animal charcoal given orally three or four times a day is sometimes effective. Dihydroergotamine, given by injection, is sometimes helpful, but it is important not to use it too frequently because of possible toxic effects. Prolonged T-tube drainage of the common duct is sometimes necessary and usually relieves the itching.

BREAST FEEDING AND DEODORANTS

To the Editor:—*A mother who is breast feeding her infant has had great variations in milk supply. She believes that her use of a deodorant and antiperspirant has caused marked reduction in the available milk. Abstinence from the antiperspirant has apparently allowed an adequate flow of milk within 36 hours. Is there any available data on this subject?*

Mack J. Mosely Jr., M.D., Galveston, Texas.

Answer.—The quantity of breast milk that becomes available during the period of lactation is dependent, in the main, upon (1) the inherent ability of the lactating glands to secrete and (2) the ability of the infant (or pump) to completely empty each breast at least three times within 24 hours. It seems quite conceivable that during the application of deodorants and antiperspirants in the axillas, sufficient material reaches the breasts and nipples to provoke a distaste so that the infant does not empty the breasts, which then quite promptly secrete less. It seems very doubtful that the external and superficial application of such material exerts a direct antigalactagogue action.

FORMALDEHYDE HAZARD

To the Editor:—*In the Questions and Answers section of* The Journal *for Aug. 23, 1958, page 2157, a physician inquired about formaldehyde hazard resulting from the manufacturing of the new resinate wash-and-wear garments. I would add to the reply of the consultant that there has been considerable difficulty with irritation, presumably from the formaldehyde vapor, in retail establishments selling these garments. Such difficulty usually occurs only during warm weather, and as soon as cooler temperatures prevail there is no longer any difficulty. The problem that has shown up has been one primarily of irritation of the skin and nasal mucosa. Such a situation has recently been reported from the Baltimore Health Department. There is apparently some dispute about the exact reason for the plant closing in Phoenix, Ariz., to which the inquiring physician referred. There is perhaps some question as to whether the illness actually resulted from employees handling urea-formaldehyde resins.*

Mitchell R. Zavon, M.D.
University of Cincinnati College of Medicine
Cincinnati 19.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*As earlier noted, when polymerization of urea-formaldehyde resin is complete no untoward effects are expectable. In the application of this resin together with the catalyst to textile material, complete polymerization is not always achieved. In some situations this occurrence may be accidental; in others it may be deliberate. In the formulation of this resin some excess of formaldehyde may be provided. One stated reason is that this excess masks the ammonia odor of urea or, to the same end, paralyzes the odor receptors within the nasal mucous membrane. The chemical form of the formaldehyde may be uncertain, but through absorption or adsorption of this gas or a compound thereof it is retained in or on the fibers. This may be influenced by the quantity of the catalyst applied. The group of workers most likely to be affected are garment workers from fabric earlier treated. Some difficulty may continue to the wholesale and retail trade. In department stores the elevated temperature of summer does not per se increase the exposure. Indirectly the situation derives from elevated temperature, in that department stores provide air conditioning with complete recirculation of air. This recirculation tends to build up the formaldehyde level. The commonest manifestation is eye inflammation from direct irritation. More serious situations, such as dermatitis or asthma, may be attributed to allergic response to formaldehyde sensitization.*

MAGNESIUM SULFATE DRESSINGS

To the Editor:—*In the Questions and Answers section of* The Journal, *May 3, 1958, page 145, there was a question concerning the use of magnesium sulfate dressings. The answer given concerned a discussion of osmosis—the action of hypertonic salt solutions in causing fluid to flow from areas of lesser to greater osmotic tension. This is all well and good; however, the most important aspect of osmosis, that is, the semipermiable membrane, was not mentioned. If it was meant to be implied that the unbroken epithelium acts as a semipermiable membrane, then this is a new concept to me. As an ophthalmologist I make frequent use of hot soaks to the eyelids; however, I have always felt that the heat with its vasodilating properties was the only beneficial aspect of this type of therapy.*

Capt. T. J. Tredici, Scott Air Force Base, Ill.

The above comment was referred to the consultant who answered the original query, and his reply follows.—Ed.

To the Editor:—*The fact that heat causes superficial vasodilatation in no way proves augmentation of blood flow in the underlying inflamed area. Recent studies (Lewis,* J. Physiol. 140:285, *1958) correlate the reversal of inflammation with the formation, within the inflamed area, of pharmacodynamically active polypeptides with vasodilating and permeability altering properties. The peri-inflammatory fibrinous membrane is highly effective in preventing the entry of blood, antibodies, prescribed antibiotics, etc., (Dubos, Biochemical Determinants of Microbial Diseases, Cambridge, Mass., Harvard University Press, 1954) into the target zone. Even if heat did get by the fibrin barrier, how could it eliminate such mechanical barriers to small vessel blood flow as interstitial edema and the vascular and lymph compressive effects of dense inflammatory exudation?*

The key factor in reversing inflammation, in the opinion of this consultant, is a change in the permeability or, more properly, the impermeability of acutely injured tissue. This constitutes the basic rationale for the anti-inflammatory effects of systemically administered proteolytic enzymes (Innerfield, Ann. New York Acad. Sc. 68:167, *1957) and, indeed, the application of soaks or wet dressings.*

Continuous wet applications have a macerative effect on the skin, thereby injuring and altering the permeability of the interepithelial cement matrices. Actual penetration and seepage of applied fluid to the inflamed zone is the basic aim of soaks. When successful, increased permeability of the inflammatory membrane occurs and drainage ensues. The justification for making the solution hot would be the factor of increasing blood flow after modification of tissue impermeability had been achieved.

FROM THE WASHINGTON OFFICE OF THE AMERICAN MEDICAL ASSOCIATION

Civil Air Surgeon Post Set Up . .
HEW Official Cites Aged Health Needs . .
Emergency Medical Stops by Planes . .
Medicare Defines Residing with Sponsor . .
Miscellany . .

POST OF CIVIL AIR SURGEON PROPOSED

Federal Aviation Administrator E. R. Quesada has proposed the position of Civil Air Surgeon in the new Federal Aviation Agency. The action thus promises new status for civil aviation medicine considerably beyond that in the old Civil Aeronautics Administration and in accord with recommendations of the American Medical Association.

The air surgeon will be directly responsible to the FAA administrator. His major function, as spelled out by Mr. Quesada, will be to direct the civil aviation medical program and work toward the improvement of safety in air commerce "through the development and application of sound medical knowledge and research in civil aviation." In a summary of the position, the administrator stated:

"Health and medical problems pervade a large segment of FAA's organization. Research and development activities and the design and installation of facilities involve psychological and human engineering considerations.

"The number of applicants for pilot's, flight engineer's, and other airmen's certificates who must be examined and reexamined exceeds 250,000 annually. Medical research or study is required with respect to the physical and mental stress, and fatigue and the over-all working environment of aviation personnel including air traffic controllers who are directly responsible for the safety of people and equipment in flight."

Among the responsibilities of the Civil Air Surgeon would be:

1. Establish minimum standards of mental and physical fitness for flight personnel, air traffic controllers, and such other personnel deemed necessary for flight safety.
2. Provide medical examinations of such personnel by approved medical examiners.
3. Provide inspection and appraisal of examiner facilities and procedures to insure proper assessment of physical fitness and enforcement of regulations.
4. Promote training activities to improve the proficiency of medical examiners.
5. Establish requirements for and encourage research in the field of aviation medicine.
6. Develop and conduct internal health and medical programs for FAA personnel.

FAA listed these qualifications for the post, which will pay between $17,500 and $19,500: no specific age category but physical and mental agility and vigor, a medical degree and license to practice, plus certification by the American Board of Preventive Medicine in aviation medicine or certification in a related speciality with suitable experience in aviation medicine.

Progressively responsible experience in the administration of medical programs will be required.

HEW OFFICIAL WARNS ON AGED HEALTH CARE

A Department of Health, Education, and Welfare official says the cost of health care for the aged has become "a political problem of great moment" and it "will not go away." Assistant Secretary Elliot Richardson, addressing the American Public Health Association, declared:

"The real issues center around the degree of public action thereby demanded. The federal government is already contributing to the provision of medical care for old-age assistance recipients, and is deeply involved in helping provide adequate facilities for the care of the chronically ill."

Mr. Richardson pointed out that, despite recent progress by private and voluntary institutions in helping the aged to meet the costs of health care, the "remaining gaps are serious and difficult to close," and the activities of local jurisdiction in working out solutions are "spotty, sporadic, and, for the most part, inadequate."

Too few communities, he said, have adequate facilities for long-term care of the chronically ill and dependent elderly persons, and very few places pay full costs for the hospital care of the indigent, many of whom are aged. "Unless private, voluntary, or local solutions to these and similar problems are found, the pressure for action at higher levels of government will continue to mount."

There are now 15 million persons over 65 in the U. S. and in a very few years there will be 20 million, Mr. Richardson predicted. "Every available medical, nursing, and custodial resource is taxed to the utmost to care for the health needs of our aged population, and still we are not doing enough or doing it as well as we know how. Still more severely affected are the families called upon to meet the medical expenses of an aged relative. The prolonged and expensive illness of a grandparent may even in some instances have a restrictive impact on the education of his grandchildren."

CAB PROPOSES EMERGENCY MEDICAL STOPS

The Civil Aeronautics Board is prepared to change commercial flight regulations to permit planes to make unscheduled stops in order to provide transportation for persons in need of emergency medical treatment. CAB has issued a proposed rule change and given all persons interested in commenting until Nov. 26 to file communications.

Under present regulations, CAB has prohibited certain air carriers from engaging in local air transportation between certain points on their routes. The policy has been known as a "closed door" restriction and has been done solely because of the economics of air transportation industry and the system of regulations set up under the Civil Aeronautics Act.

The board recently was advised of a case in which an airline operating under the closed door policy was prevented from providing air transportation to a person in need of emergency medical treatment. Comments the CAB in its notice of proposed rule change:

"Under such circumstances, a closed door restriction operates contrary to the public interest and, if requested, would undoubtedly warrant the board's granting relief from such restrictions in each individual case. It is evident, however, that this procedure would frequently not be feasible.

"Recognizing that requests for such emergency transportation would be made infrequently and that competitive considerations would, thus, be negligible, it is the board's view that to require the air carriers to secure a modification of their certificates under such circumstances would be an undue burden on such air carriers by reason of the limited extent of, and unusual circumstances affecting, their operations and would not be in the public interest."

MEDICARE EXPLAINS 'RESIDING WITH SPONSOR' STATUS OF DEPENDENTS

In response to inquiries, the Office for Dependents' Medical Care has explained the eligibility status of dependents who reside apart from sponsors at the time medical care commences but rejoin the sponsor before completion of treatment. "As a general rule," ODMC says, "such care may be continued (from civilian sources) without a Medicare permit."

ODMC then goes into detail, explaining that readmission to a hospital is authorized within 14 days after discharge without a permit. However, in a maternity case, the wife rejoining her spouse during treatment is not eligible for continued civilian care (without a permit) if she changes her physician for any reason other than death or illness of the physician.

NATIONAL AIR POLUTION CONFERENCE

Officials of the Department of Health, Education, and Welfare, announcing plans for the National Conference on Air Pollution, say they hope the November meeting will result in a unified 10-year plan of action in research and control activities. The conference will be held in Washington November 18-20.

"As with other resources once taken for granted, we are discovering that our usable air supply is not limitless and cannot be abused with impunity," a statement from HEW declares. "Until recently, the principal target for control has been visible pollution such as smoke and soot produced by burning solid fuels. Nowadays, smoke is only one of a number of contaminants."

HEW explains that exploration of the short and long-range effects of polluted air on our health is still in its early stages. "We know, however, that man-made pollution combined with natural fog caused 20 deaths in Donora, Pa., in 1948 and several thousand deaths in London in 1952 and 1956. And we have no guaranty against similiar disasters elsewhere."

The annual air pollution cost for the country has been estimated at between 1.5 and 4 billion dollars, exclusive of effects on health which cannot yet be accurately measured and the many intangibles which result from living and working in an unpleasant environment."

MISCELLANY

Dr. Aims McGuinness, special assistant to the Secretary of Health, Education, and Welfare, addressing the American College of Preventive Medicine warned that "unless there is a substantial increase in the production of physicians and other professional health personnel, not only the total research effort but the health services of the nation will be severely hampered in the years ahead."

A number of physicians are scheduled to speak at the National Conference on Air Pollution called by the Public Health Service for Nov. 18-20. Dr. Oscar A. Sander of Milwaukee represented the American Medical Association on the planning committee. Surgeon General Burney will present a status report to the nation on progress in the five-year program of research and technical assistance to the states in air pollution. HEW Secretary Flemming will address the conference on "What of the Future?"

Researchers and clinicians met in Washington to lay the groundwork for new research on the effects of tranquilizers and other drugs on children, both normal and those emotionally disturbed or mentally retarded. The conference was called by Psychopharmacology Service Center of the National Institute of Mental Health.

OCDM has published a revised edition of the family handbook, "What to Do Now About Emergency Sanitation at Home." The 22-page publication is available at the Superintendent of Documents, Government Printing Office, Washington 25, D. C., for 15 cents a copy.

A 20-page pamphlet on the 1960 White House Conference on Children and Youth has been prepared as a guide to organizations concerned with conference preparations. Those interested may write the conference headquarters, 330 Independence Ave. S. W., Washington 25, D. C.

DIAGNOSIS OF PERIPHERAL ARTERIAL EMBOLI OF THE EXTREMITIES

John T. Phelan, M.D.
and
William P. Young, M.D., Madison, Wis.

The clinical features of an acute peripheral arterial embolus are considered to be a rigidly fixed series of events, namely, sudden, abrupt, excruciating pain followed by numbness, pallor of the extremity, and absent pulsations. However this sequence of events may be the exception rather than the rule, inasmuch as the onset of pain may be insidious and, in some instances, preceded by paresthesias of the involved extremity. In many instances the diagnosis of a peripheral arterial embolus depends on the assessment of minor signs and symptoms. Next to pain, the vascular disturbances manifested by absent arterial pulsations and color and temperature changes in the involved extremity are prominent features of an acute arterial occlusion. The frequent association of cardiac abnormalities with peripheral arterial embolus should be well known. In addition there is a prevalence of emboli involving the femoral artery.

RECENT observations by a number of authors have shown that early diagnosis of a peripheral arterial embolus, followed by its surgical removal with restoration of blood flow whenever possible, will, in most instances, be superior to conservative measures in terms of patient mortality and morbidity.[1] Furthermore, accumulative clinical data have suggested that surgical treatment is most effective when employed within the first 24 hours after lodgment of the embolus. However, in most reported series,[1] a large percentage of the patients have presented signs and symptoms for at least 24 hours or longer before surgical attention was considered; in this regard, our series is no exception. In evaluating this problem, we found a certain number of patients who had disease conditions that were considered at the time to be contraindications to surgical removal of the embolus. Still, in a number of cases the atypical clinical course suggested to the attending physician a condition other than an acute arterial occlusion. Hence, surgical intervention was delayed, and, in most instances, the patient presented ischemic changes of an irreversible nature at the time of surgical evaluation.

Because of this problem, this report concerns a clinical review of patients seen with peripheral arterial emboli of the extremities at the University Hospitals, with particular attention given to the signs and symptoms of this condition and emphasis on early diagnostic criteria.

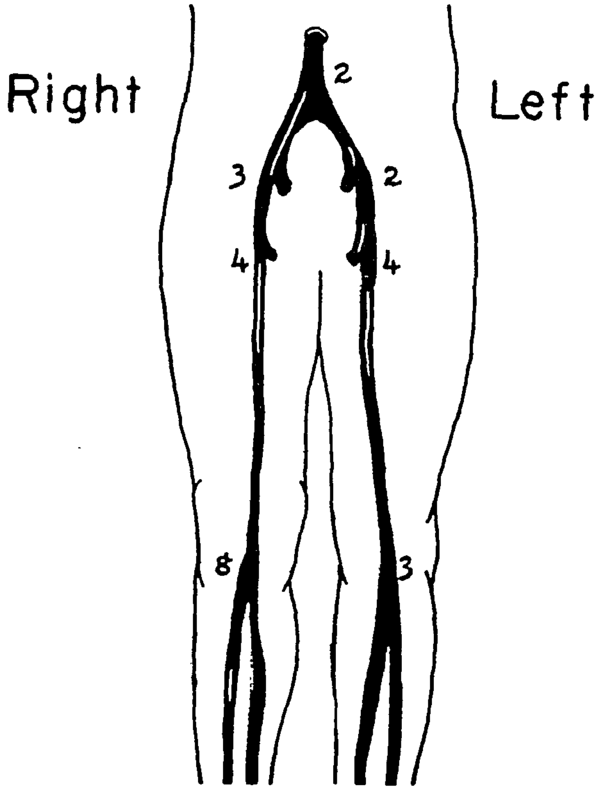
From the Department of Surgery, University Hospitals, University of Wisconsin School of Medicine.

From June, 1951, to January, 1957, inclusive, the diagnosis of peripheral arterial emboli involving the upper and lower extremities was made in 30 patients. Data gleaned from a critical review of the clinical records of these patients constitute the basis of this report.

The youngest patient in our series was 39 years of age, while the oldest was 79. The average age of the patients in this group was 62.

Etiology

In most collected series of this nature[2] cardiac conditions manifested by auricular fibrillation, mitral valvular disease, and recent myocardial infarction have been found primarily responsible for the etiology of the embolus. Our findings were quite similar, and to present them in detail would only be a repetition of a known fact. However, in five instances chronic congestive heart failure was the only cardiac finding, a point that has been afforded little emphasis with respect to the etiology of a peripheral arterial embolus. Unmistakable clinical evidence of cardiovascular disease was present in 29 of the 30 patients. Particular diagnoses included auricular fibrillation, 19; congestive heart failure, 5; mitral valvular disease, 3; and myocardial infarction, 2. In only one case was the acute arterial occlusion considered to be a primary thrombosis.



Sites of lodgment of emboli in 26 patients with acute peripheral arterial occlusion (in four instances upper extremity was involved).

Location and Symptoms

Location.—The sites of lodgment of the emboli, as determined by physical examination, surgical arterectomy, and autopsy examinations, are shown in the figure. The prevalence of emboli involving the femoral artery is to be noted.

Symptoms.—Pain heralded the onset of a peripheral arterial embolus in 24 of the 30 cases. In five instances the embolic event was manifested initially by paresthesias of the extremity, while one patient experienced a weakness of the involved limb as the initial symptom.

Twenty-four of the 30 patients presented a combination of two or more of these subjective symptoms, namely, pain, followed by paresthesia (numbness, coldness, tingling, and heaviness), and/or paralysis.

The 24 patients whose initial symptom was pain described this sensation under a variety of terms which ranged from excruciating pain to simply a mild ache. In 18 instances the pain was abrupt and sudden and was frequently described as severe or excruciating in character. Although our records are incomplete, it was suggested that such pain manifested itself in one or two ways: either it was localized initially to specific regions of the extremity, namely, foot, hand, calf, popliteal space, or groin, or, less frequently, it involved the entire limb. Furthermore, its duration was variable, for, in some cases, it persisted for three to four hours and in one case less than one hour, only to be replaced by a numb distressful feeling to the limb. Still others noted the pain to be continuous and to involve the entire limb during the first 24 hours. It was also our impression that in some cases the character of the acute pain gradually subsided, only to be replaced by an ischemic, neuropathic type of pain.

As previously stated, six patients noted the onset of pain to be insidious in nature and most frequently described it as an aching sensation. In one case the entire limb was involved, while the remaining five patients indicated the site to be either the foot or the region below the knee. Four patients noted the pain to increase in intensity and severity during the first 24 hours; the other two patients noted little increase in its intensity except when the limb was exercised. It was of interest that each of these six patients complained of coldness of the involved extremity.

Paresthesia.—Eighteen patients in this series experienced some type of paresthesia. In 10 cases it was described as numbness and in 7 as coldness of the extremity; these two subjective sensory complaints were present in combination in nine instances. In addition, tingling, burning, and heaviness of the involved limb were noted by three patients. As previously stated, in five patients the above sensory disturbances were the initial complaint referable to a peripheral arterial embolus. In three instances pain followed and was mild in two patients and severe in another, and, in each case, it persisted for at least 24 hours; in two patients, the pain was not felt until the limb was exercised and intermittent claudication was noted.

Motor Findings.—In six instances, paralysis of the involved extremity or a specific group of muscles was observed. In five cases the motor changes followed other subjective symptoms; however, in one case its presence was the first evidence of an acute arterial occlusion. The onset of muscular paralysis was variable, and in one patient it was apparent within 10 minutes after the embolic episode. In one case the entire extremity was completely paralyzed, while in the remaining five patients only the foot and toes were involved. In no instance were the motor findings transient, but once they made their appearance they became permanent unless the ischemia was relieved.

As many of our patients were seen hours or days after their embolic event, signs of advanced ischemia were unmistakably evident. However, in seven instances the interval between onset and hospital admission was less than six hours, and in four the acute arterial embolus occurred during the patient's hospitalization for some other condition. From this group, certain definite observations were available. First, in four patients, pallor of the extremity was the initial color change and, in time, (the earliest within 30 minutes, the longest 24 hours) cyanosis was recorded in the initial color change. In four instances the color change was manifested by a visible line of demarcation at the knee level. In three patients the foot and ankle presented this phenomenon.

Second, a temperature difference was distinguished in each patient, which corresponded with the color change. In three patients this difference was more diffuse and extended beyond the color line.

Comment

The clinical features of an acute peripheral arterial embolus are considered to be a rigidly fixed series of events, namely, sudden, abrupt, excruciating pain followed by numbness, pallor of the extremity, and absent pulsations. However, as indicated by the data presented here, this sequence of events may be the exception rather than the rule, inasmuch as the onset of pain may be insidious and, in some instances, preceded by paresthesias of the involved extremity. Moreover, in one of our patients, motor weakness of a specific group of muscles was the first indication that an acute peripheral arterial embolus had taken place. These observations are not original, as a number of authors have recorded similar findings; however, their importance as diagnostic criteria of an arterial embolus has not received due emphasis.

For example, Allen and his associates,[3] at the Mayo Clinic, reported that only 48% of patients in their series experienced an abrupt onset of symptoms. This figure corresponds closely to that given by Haimovici,[2] who found sudden pain to be the *principal clinical feature in only 60% of the patients* in his series of 330 cases of embolism, and by Richards,[4] who found that 11 of his 48 patients experienced symptoms other than acute pain. Our own experience is quite similar, for of the 30 cases of peripheral arterial emboli the onset of symptoms was abrupt in 18. In five patients numbness of the extremity replaced pain as the dominant symptom, and in six pain was the first symptom; however, its character was not the intense, sudden, agonizing pain one frequently associates with this condition. This factor accounted for delayed diagnosis in the great bulk of these cases seen in this series.

This atypical clinical symptomatology in some cases of peripheral arterial emboli is difficult to explain, since analysis of our cases indicates this feature was not related to age or location of the embolus. Richards [4] has discussed this problem quite succinctly in a recent paper and relates that Lewis, in 1936, considered the pain of an acute arterial occlusion to be directly related to the degree of muscle ischemia. However, the variance of this one symptom has suggested to Richards that muscle ischemia is not the sole underlying mechanism. He believes that dilation of the artery by the embolus may be an additional and principal factor in explaining the sudden onset of pain and its localization to a specific part of the extremity. Furthermore, he indicates that this dilating component may be absent and the artery lumen only partially occluded in those cases where the pain is slowly progressive or is preceded by paresthesias of one type or another. Still others tend to link the appearance of acute pain with arterial spasm, a factor Richards believes has received more emphasis than it rightly deserves in the etiology of pain in an acute arterial occlusion.

Next to pain, the vascular disturbances manifested by absent arterial pulsations and color and temperature changes in the involved extremity are prominent features of an acute arterial occlusion. In our series, we found pallor of the extremity to be an early event and this was followed by cyanosis of the involved limb. In addition, the finding of absent, or diminished, arterial pulsation was, in each instance, accompanied by color and temperature change.

The frequent association of cardiac abnormalities with peripheral arterial embolus is a well-known fact, and in our series such was the finding in 29 of the 30 patients. Hence, the presence of auricular fibrillation, mitral valvular disease, recent myocardial infarction, and congestive heart failure are so closely allied with this condition that their presence alone in patients who present atypical motor and sensory disturbances to one or more extremities should suggest the presumptive diagnosis of an arterial embolus until proved otherwise.

Summary

In one-third of 30 cases of acute peripheral arterial occlusion, the onset of symptoms, principally pain, was insidious and, in some instances, paresthesias preceded the latter as the chief symptom. In the remaining cases the abrupt onset of pain was characteristic; however, its duration and behavior were uncertain. These findings suggest that in many instances the diagnosis of a peripheral arterial embolus will depend on the assessment of minor signs and symptoms, a concept that is in contrast to the usual expectation of an acute artery occlusion, namely, a sudden, painful, dramatic event.

PREVENTION OF URINARY CALCULI AFTER PARALYTIC POLIOMYELITIS

Fred Plum, M.D., Seattle

Urinary calculi after poliomyelitis are largely confined to long-term respirator patients. Prophylaxis of calculi can be effective if begun early in the paralyzing and immobilizing diseases. Proper positioning is required to prevent stasis of crystalline material in the genitourinary tract. Calcium intake of 500 to 700 mg. daily was achieved by limiting milk and milk products to the equivalent of one and one-half glasses. Having patients produce 1,500 to 2,000 ml. of urine daily is the hardest task in the prophylactic program. Placing fluid reservoirs, connected to self-service drinking tubes, next to each patient aided in attaining a high fluid intake. The medical problem of renal stones was discussed frequently in lay language with the patients as a group. Once the problem was understood by some of the patients, one or more usually prompted the rest to work toward the required fluid volumes. A program of prophylaxis of urinary calculi appears to be widely applicable.

Prophylaxis of urinary lithiasis is an important part of the management of patients with paralytic neurological diseases. The development of urinary calculi may otherwise produce as much disability, or more, than that caused by the paralysis itself.[1] Several analyses indicate that patients severely paralyzed by poliomyelitis frequently develop calcium phosphate urinary calculi. Calculi were found in 33 (33.7%) of 98 long-term and in 1 of 32 short-term respirator patients by Taylor, Alcock, and Hildes.[2] No stones were present in 112 nonrespirator patients with spinal paralysis. Slotkin, Loeser, and Ament [3] reported renal stones in 19 (40.4%) of 47 consecutive respiratory patients. Rodgers, Ellwood, and Ratelle [4] noted that 22 (33%) of 66 adult respirator patients and 8 (31.6%) of 25 children in respirators developed stones. Calculi were found only twice in nonrespirator patients with spinal paralysis. Affeldt [5] detected renal calculi in 14.9% of 675 convalescent patients at the Rancho Los Amigos Respiratory Center. The incidence rose to 23% in the 338 patients over 20 years of age.

Pathogenesis

Hypercalciuria and Hyperphosphaturia.—Skeletal demineralization with hypercalciuria and hyperphosphaturia almost invariably follows paralytic poliomyelitis.[6] Hypercalciuria, in the immediate weeks after the onset of poliomyelitis, tends to be intense in both mildly and severely paralyzed patients. Subsequently, the duration of hypercalciuria is proportional to the degree of paralysis, and an increased urinary calcium content may continue for 6 to 12 months or more in patients with paraplegia or quadriplegia.[6b] Artificial mobilizing procedures have little effect on the intensity or duration of the calcium losses.[7]

Well-controlled studies on the effects of dietary calcium on urinary calcium excretion are limited. Howard, Parson, and Bigham [8] noted only inconse-

Read before the Section on Nervous and Mental Diseases at the 107th Annual Meeting of the American Medical Association, San Francisco, June 27, 1958.

quential changes in the urinary calcium of patients with fractures after large shifts in dietary calcium. However, Dunning and I[7] observed a rise in the serum calcium from 11.8 to 13.1 mg. per 100 cc. within two weeks in a boy with paraplegia due to poliomyelitis when the daily calcium intake was raised from 0.5 Gm. to 1.5 Gm.

Reduced Urine Flow.—Hypercalciuria and hyperphosphaturia increase the amount of urinary solutes. Diminished fluid intake due to a combination of anorexia and increased insensible water losses may decrease the renal clearance of water at the same time. A further rise in urinary solute concentration results.

Urinary Tract Infection.—Many poliomyelitis patients require catheterization to drain transiently paralyzed bladders. Few escape infection with urea-splitting bacteria after this procedure; an alkaline urine results, in which calcium phosphate can exceed its solubility constant and precipitate as apatite and struvite.[9] Infection also creates both denuded areas of urinary tract mucous membrane and exudates of organic material which may provide the matrix for stone formation.[10] It has been noted previously that stones that appear after poliomyelitis are apt to be restricted to patients with urinary tract infection.[11]

Stasis.—The posterior renal calyces fail to drain by gravity except when the patient is in the prone or erect position.[12] Hence, in recumbent immobilization any material which precipitates in the urine tends to drift into and remain stagnant in the dependent calyces. The combination of an increased calcium phosphate excretion, decreased urinary flow, a urine pH favoring precipitation of crystalline material, a readily available organic detritus for matrix formation, and stagnant regions from which drainage is limited creates a formidable risk of calculi. Other factors, such as the respiratory alkalosis which results from chronic respirator treatment,[13] may contribute to this risk.

Prophylaxis

Clinical Material.—This study was initiated at the New York Hospital in 1949 and continued from 1953 until the present at the Northwest Respirator and Rehabilitation Center of the University of Washington, Seattle. Of the 500 or more patients with poliomyelitis admitted to the two institutions, there were 115 with extensive paralysis who were under direct observation for periods lasting six months or more. Forty-one were at the New York Hospital and the remainder were treated in Seattle.

Twenty-five patients had severe paralysis of the trunk and extremities (total paraplegia, triplegia, or quadriplegia) without requiring respirator care. Twenty extensively paralyzed subjects required short-term (six weeks or less) treatment in the respirator, and 69 other extensively paralyzed patients required long-term (more than six weeks) respirator treatment. Among the respirator patients, 55 were under our supervision during both the acute and convalescent stages of poliomyelitis. Measures designed to prevent the development of urinary calculi were carried out in these 55 patients throughout their entire illness. This will be referred to as the "early treated" group. Thirty-four respirator patients were transferred to us from other hospitals for rehabilitation care at intervals ranging from two months to three years after the onset of poliomyelitis. These patients had not previously been on a program particularly designed to prevent renal calculi and were designated the "late treated" group.

Treatment Program.—Patients on this service were maintained on a low calcium intake, between 500 and 700 mg. daily. Fluids were forced to produce a measured urinary output of 1,500 to 2,000 ml. of urine per day. Urinary tract infections were treated promptly. All patients, including those in respirators, were turned from side to side several times daily and placed prone as early in convalescence as possible. Rarely was prone positioning delayed longer than four weeks after the onset of treatment. Seven respirator patients, three in the early treated group and four in the late treated group, received norethandrolone (Nilevar) during a metabolic study of this agent.[14] No specific metabolic measures were employed to influence the solute excretion in the other patients. Each patient underwent a general program of convalescent care and rehabilitation and was mobilized as rapidly as his disability permitted.

Detection of Calculi.—Several methods were used to detect urinary calculi. Every patient was under direct clinical surveillance in the hospital for an average of six months during rehabilitation therapy. Periodic x-rays of the abdomen to show calcification in the kidneys, ureters, and bladder were taken on each patient, particularly prior to discharge from the hospital. In addition, all of the patients studied at the Northwest Respirator Center had intravenous pyelograms. Clinical follow-up by questionnaire to determine the incidence of late urinary complications was accomplished in 1954 on 33 of the 41 New York Hospital patients. Either direct clinical and x-ray follow-up or a follow-up through the current attending physician has been achieved for an average of three years to date on all of the Northwest Respirator Center patients.

Incidence of Urinary Calculi.—The table summarizes the extent of paralysis and incidence of calculi. Urinary lithiasis was detected in respirator-treated patients only, and renal calculi were limited to those patients who had been in respirators for more than six weeks. The figure diagrams the relationship between calculi and the age and sex of the respirator-treated patients.

Three early treated respirator patients developed calculi, an incidence of 5.5%. One boy had a large right renal calculus necessitating surgical removal of both stone and kidney at another hospital two years after the onset of poliomyelitis. One young woman first showed tiny calcifications in the region of the right renal pelvis two years after the onset of poliomyelitis. The early care of both these patients had been hampered by great difficulties in changing them from the recumbent position. Their treatment had not otherwise differed from the rest of the early treated group. The third early treated patient with urinary lithiasis developed several small bladder calculi after eight months of indwelling catheterization. She had lumbosacral sensory loss and bladder paralysis associated with acute poliomyelitis.[15] After removal of the bladder calculi by transurethral crushing and a partial resection of the internal urethral sphincter, she has had no other urinary problems for two ensuing years.

Extent of Paralysis and Incidence of Calculi Among 115 Patients

	Patients, No.	With Calculi, No.
Severe spinal paralysis only	25	0
Short-term respirator		
treated early	14	1
treated late	6	0
Long-term respirator		
treated early	41	2
treated late	28	9
Total, early treated respirator cases	55	3(5.5%)
Total, late treated respirator cases	34	9(26.5%)

Nine (26.5%) of the 34 late treated respirator patients developed calculi, eight in the kidneys and one in the bladder. Large stones in the renal calyces and pelves were present in five late treated patients. These calculi were successfully removed surgically in three patients while symptoms were controlled by conservative treatment in the other two who were precarious surgical risks. The calculi in three late treated patients were asymptomatic and detected only as small radiopaque densities in the region of the renal calyces. One late treated patient showed several small bladder calculi which necessitated transurethral removal. He had had an indwelling catheter for six weeks during his acute illness and early convalescence.

All 12 patients with established calculous disease had been catheterized during acute poliomyelitis and all had persistent bacilluria with organisms of the coli-aerogenes group. Catheterization had also been performed during acute illness in most of the other respirator patients; the majority had bacilluria with gram-negative organisms at some time during convalescence.

The care of the late treated patients during the first few weeks or months after poliomyelitis differed in several respects from the prophylactic program established for the 55 patients treated from onset of poliomyelitis. Reference to the clinical notes and interviews with the patients indicated that a minority of the late treated patients had been on a restricted calcium intake. Several, including one young woman who showed diffuse renal calcinosis within eight weeks after the onset of poliomyelitis, had had generous milk shake and ice cream supplements. No emphasis had been placed on a high urine output. Few of the late treated patients had been changed from the recumbent position either during their acute illness or in early convalescence and several had been supine for months. However, most of the late treated patients had received appropriate antibiotics for urinary tract infections.

Comment

This study confirms the fact that urinary calculi after poliomyelitis are largely confined to long-term respirator patients.[2] Two of 55 early treated respirator patients and 8 of 34 late treated respirator patients had renal calculi. This contrast in renal stone incidence was striking and indicates that prophylaxis of calculi can be effective if begun early in the paralyzing and immobilizing diseases.

The excellent cooperation of nurses and dietitians made the prophylactic treatment program possible. A calcium intake of 500 to 700 mg. daily was achieved by limiting milk and milk products to the equivalent of one and one-half glasses. Milk products were reduced further when large amounts of fruit juices were taken, since the latter contained approximately 8 mg. of calcium per 100 cc. Extra milk shakes, ice cream, cheese, and milk-base eggnogs were foregone until the expected duration of postparalytic hypercalciuria had passed. This was never less than six months after onset of poliomyelitis.

Having patients produce 1,500 to 2,000 ml. of urine daily was the hardest task in the prophylactic program. Orders to "force fluids" were no guarantee that dilute urines would result, so output measurements were checked frequently. The patients had large insensible water losses, particularly in warm weather, and moderate anorexia often impeded thirst. The extensive paralysis suffered by these patients meant that an attendant was ordinarily required to administer fluids and to empty urinals. Both the patients and the attendants found this irksome. (An example may illustrate some of the difficulties: If a patient takes half a glass of liquid

Top line in each square indicates women, bottom lines, men.

at each feeding and requires a 3,800 ml. intake to maintain an 1,800 ml. output, 38 separate daily trips by nursing staff are required for fluid intake alone.)

The problems in attaining a high fluid intake were met in several ways. Much of the nursing time required was eliminated by placing fluid reservoirs, connected to self-service drinking tubes, next to each patient. These reservoirs were attached to respirators when necessary. The medical problem of renal stones was discussed frequently in lay language with the patients as a group. Once the problem was understood by some of the patients, one or more usually prompted the rest to work toward the required fluid volumes. The fluid intake was supplemented by intravenous infusions if persistent anorexia or nausea prohibited adequate gastrointestinal ingestion. It was rarely necessary to resort to parenteral routes except during intercurrent infections.

Another purpose behind forcing fluids was to minimize the severity of urinary tract infections. Patients with positive urine cultures were treated for limited periods by specific antibiosis after in vitro sensitivity testing. These measures usually controlled the clinical manifestations of infection, but persistent bacilluria was frequent. Prophylactic or prolonged antibiosis was not employed. Infections with drug-resistant organisms were treated by an increased fluid intake. Efforts to change the urine pH by drugs or diet were met with only limited success.

After the third month of convalescence, those patients with calculi had frequent urinary tract infections. Acute urinary tract infections after the sixth month of convalescence were reported on follow-up examination by only four patients, who had no demonstrable calculi. In contrast, 8 of the 12 patients with calculi gave histories of either periodic dysuria, flank pain, or acute episodes of pyelocystitis occurring repeatedly in convalescence.

Proper positioning to prevent stasis of crystalline material in the genitourinary tract required considerable efforts by nurses, particularly for patients in respirators. Nonrespirator patients were turned to the prone position at least once daily throughout both acute and convalescent illness. The patients in body respirators were transferred to rocking beds early in convalescence and most could be placed prone shortly afterwards. Passive standing on a tilt table was also employed for many patients to induce gravitational drainage of the kidneys.

Some late treated patients who had remained supine for several months after the onset of poliomyelitis had untoward reactions when changed from the recumbent position. When first placed prone, they passed macroscopic urinary concretions of calcium phosphate salts, producing both pain and hematuria. These complications were minimized by inducing a high urine output for several days before starting prone positioning.

The present study reaffirms the importance of interrupting recumbency to prevent urinary calculi in paralyzed and immobilized patients. There was no way of telling how much protection was added by the other treatment measures. Both of the early treated patients who developed calculi suffered from unusually severe immobilization in the supine position during the first part of their illness. Henceforth, such severely immobilized patients will be treated with testosterone-estrogen combinations or with norethandrolone. These hormones ameliorate hypercalciuria [16] and their addition to the regimen may add some protection for patients in whom recumbency is unavoidably prolonged. However, the low incidence of stones among early treated patients whose position in bed could be changed indicates that special hormones or drugs [17] are unnecessary to protect the majority of appropriately treated paralyzed patients. Other paralyzing and immobilizing diseases produce metabolic changes similar to those which follow poliomyelitis.[18] Therefore, this program of prophylaxis of urinary calculi appears to be widely applicable.

Summary

The incidence of urinary calculi was determined in 115 patients severely paralyzed and immobilized by poliomyelitis. Calculi developed only in respirator patients and were rare unless respirator treatment had been continued for six weeks or more.

A program of prophylaxis of urinary lithiasis was employed which included limiting the calcium intake, insuring a large urine output, promptly and briefly treating urinary tract infections, and minimizing urinary stasis by not allowing patients to remain in the recumbent position for long periods. These measures were initiated within the first month of illness on 55 respirator patients, 3 (5.5%) of whom subsequently developed urinary stones. Initiation of the prophylactic measures was delayed for two months to three years after poliomyelitis in 34 other respirator patients. Nine (26.5%) of this latter group developed calculi.

The effectiveness and simplicity of this regimen for protection against urinary calculi gives it wide applicability in the treatment of patients suffering from paralyzing and immobilizing diseases.

This study was aided by an annual grant from the National Foundation for Infantile Paralysis to the Northwest Respirator and Rehabilitation Center and a grant from the National Institute of Neurological Diseases and Blindness, U. S. Public Health Service.

EXAMINATION FOR MUSCLE WEAKNESS IN INFANTS AND SMALL CHILDREN

Ernest W. Johnson, M.D., Columbus, Ohio

The diagnosis of suspected muscle weakness in infants up to the age of five years is difficult unless one uses a systematic approach. The steps in the examination are (1) palpation of the muscles, (2) examination for muscle tightness, and (3) demonstration of muscle function. Palpation not only reveals tenderness but also distinguishes among conditions that affect the consistency of the muscle mass. Tightness may be seen in either the affected muscles or their antagonists during passive movements. To observe the function of individual muscles calls for much special maneuvering and close observation. Even after the child supposes the examination to be over, the movements of its arms during the act of dressing afford indications as to the status of the deltoid and other muscles of the upper extremity. Electrodiagnostic methods can prove helpful. These methods of differential diagnosis are essential to proper treatment, since they may decide, as in the case history here cited, between such conditions as poliomyelitis and polymyositis.

Frequently the practicing physician is faced with the difficult problem of examining an infant or small child with suspected muscular weakness. The experience can be less frustrating if one uses a systematic approach to the examination. A review of the current pediatric-neurological literature demonstrates the need to present a relatively simple routine for such an examination. No claims for originality are made for any of the techniques outlined; however, these methods were all developed during two years of observation of, and experience with, the diagnosis and management of muscle weakness problems in a pediatric setting.

Emphasis of this paper will be on detecting muscle weakness in those conditions affecting the motor unit, that is, the lower motor neuron and all the muscle fibers which it innervates. Poliomyelitis has been one of the common clinical conditions affecting the motor unit in children. Others include brachial plexus and nerve injuries at birth, infectious polyneuritis, progressive spinal atrophy of infancy, amyotonia congenita, muscular dystrophy, polymyositis, and postnatal nerve injuries of various

types. Upper motor neuron disorders can result in clinical weakness which may be demonstrated by the described techniques, although spasticity and reflex changes, among other neurological signs, are usually more important as diagnostic aids.

The techniques which are used represent attempts to determine whether motor weakness can be detected in specific muscle groups. When the presence and distribution of muscle weakness is determined, then additional diagnostic procedures can be undertaken.

The steps in the examination are as follows: (1) palpation of the muscle bellies; (2) examination for muscle tightness; and (3) demonstration of muscle function (with separate consideration for the infant and the walking child).

The only requirements for the examiner are a working knowledge of functional anatomy and acquaintance with the motor development of infants. The former is easily obtained by a review of an easily read anatomy textbook, such as that by Hollinshead,[1] and the latter by observation of infants and familiarity with the developmental scale of Gesell and Amatruda.[2]

Palpation

Palpation is usually the first step in examining muscles. This can provide information about tenderness and consistency of the muscle bellies. My routine includes palpation of the calf, posterior thigh, biceps, and forearm muscles. Firm, steady, slowly increasing pressure is applied over the thickest part of the muscle.

Generally, a crying infant will change the character of his cry when painful muscles are squeezed. In an older infant or young child the facial expression serves as a good indicator of muscle tenderness. If there is a probability of patient cooperation and one suspects considerable tenderness, this part of the examination should be postponed.

The resistance or "feel" of the muscle when it is palpated can often provide diagnostic information. A normal muscle belly feels firm. This is quite different from the ropy character of partially denervated muscle, the rubbery feeling of a pseudohypertrophic calf, the smooth lack of resistance of a flaccid or hypotonic muscle, the "woodeny" character of a muscle in polymyositis, or the hard, leathery nature of a muscle which has undergone fibrosis.

Making muscle palpation a part of every patient's examination will soon give the examiner confidence in detecting and differentiating muscle abnormalities.

Examination for Muscle Tightness

Muscle tightness often can direct attention to possible muscle weakness. It usually occurs in the muscle group opposite or antagonistic to the weak or paralyzed group. This is because the functioning muscle tends to be held in a shortened position. For example, in a radial nerve injury with paralysis of the wrist and finger extensors, the wrist and finger flexors may be tight. When this muscle is shortened or tight, wrist flexion must occur to provide the necessary slack to fully extend the fingers. In newborn infants with spina bifida and with questionable function in the lower extremities, tightness in a muscle group suggests function in that group.

There are many causes of joint limitation of motion other than muscle tightness, so it is incorrect to suggest that reduced joint motion per se is associated with muscle weakness. Some other causes are bony incongruity, joint effusion, capsular tightness, ligamentous abnormality, and cartilage injury. However, since most muscles cross more than one joint, muscle tightness can usually be recognized as the offender if joint motion is limited for this reason. For example, the hamstring muscle group crosses the hip and the knee, extending the former and flexing the latter. If the hamstrings are tight, that is, shortened, it will be painful and difficult to extend the knee if the hip is flexed. When the hip is extended, the knee may also be extended.

My routine is to check the calf and foot dorsiflexor tightness by dorsiflexing and plantar flexing the ankle respectively. Next, the hamstring group is examined with straight leg raising to 90 degrees with the patient in the supine position. The anterior thigh group is checked by attempting to put the heel to buttocks with the child in the prone position. Back tightness is demonstrated by attempting to put the forehead on the knees, with the patient's legs hanging over the edge of the bed. Most normal children can accomplish these flexibility tests easily. An exception to this generalization is the neonatal infant, who retains hip and knee tightness for four to six weeks after birth.[3]

The upper extremities are examined for muscle tightness in three areas. The shoulder adductors are tested by placing the arm over the head, the elbow extensors and flexors by flexing and extending the elbow, respectively, and the wrist and finger flexors by extending the wrist and finger simultaneously.

Testing Muscle Weakness

In order to understand why certain maneuvers are used to evaluate muscle weakness in infants, it is first necessary to review briefly conventional muscle grading.

In muscle testing several grades are used to indicate the degree of weakness. One common system is as follows: normal, moves through full range against considerable resistance; good, moves through full range against resistance; fair, moves through full range against gravity only; poor, moves through full range with gravity removed (i. e., weight of the part is supported); trace, tendon moves but no joint motion; and, lastly, zero, no function visible or palpable.

types. Upper motor neuron disorders can result in clinical weakness which may be demonstrated by the described techniques, although spasticity and reflex changes, among other neurological signs, are usually more important as diagnostic aids.

The techniques which are used represent attempts to determine whether motor weakness can be detected in specific muscle groups. When the presence and distribution of muscle weakness is determined, then additional diagnostic procedures can be undertaken.

The steps in the examination are as follows: (1) palpation of the muscle bellies; (2) examination for muscle tightness; and (3) demonstration of muscle function (with separate consideration for the infant and the walking child).

The only requirements for the examiner are a working knowledge of functional anatomy and acquaintance with the motor development of infants. The former is easily obtained by a review of an easily read anatomy textbook, such as that by Hollinshead,[1] and the latter by observation of infants and familiarity with the developmental scale of Gesell and Amatruda.[2]

Palpation

Palpation is usually the first step in examining muscles. This can provide information about tenderness and consistency of the muscle bellies. My routine includes palpation of the calf, posterior thigh, biceps, and forearm muscles. Firm, steady, slowly increasing pressure is applied over the thickest part of the muscle.

Generally, a crying infant will change the character of his cry when painful muscles are squeezed. In an older infant or young child the facial expression serves as a good indicator of muscle tenderness. If there is a probability of patient cooperation and one suspects considerable tenderness, this part of the examination should be postponed.

The resistance or "feel" of the muscle when it is palpated can often provide diagnostic information. A normal muscle belly feels firm. This is quite different from the ropy character of partially denervated muscle, the rubbery feeling of a pseudohypertrophic calf, the smooth lack of resistance of a flaccid or hypotonic muscle, the "woodeny" character of a muscle in polymyositis, or the hard, leathery nature of a muscle which has undergone fibrosis.

Making muscle palpation a part of every patient's examination will soon give the examiner confidence in detecting and differentiating muscle abnormalities.

Examination for Muscle Tightness

Muscle tightness often can direct attention to possible muscle weakness. It usually occurs in the muscle group opposite or antagonistic to the weak or paralyzed group. This is because the functioning muscle tends to be held in a shortened position. For example, in a radial nerve injury with paralysis of the wrist and finger extensors, the wrist and finger flexors may be tight. When this muscle is shortened or tight, wrist flexion must occur to provide the necessary slack to fully extend the fingers. In newborn infants with spina bifida and with questionable function in the lower extremities, tightness in a muscle group suggests function in that group.

There are many causes of joint limitation of motion other than muscle tightness, so it is incorrect to suggest that reduced joint motion per se is associated with muscle weakness. Some other causes are bony incongruity, joint effusion, capsular tightness, ligamentous abnormality, and cartilage injury. However, since most muscles cross more than one joint, muscle tightness can usually be recognized as the offender if joint motion is limited for this reason. For example, the hamstring muscle group crosses the hip and the knee, extending the former and flexing the latter. If the hamstrings are tight, that is, shortened, it will be painful and difficult to extend the knee if the hip is flexed. When the hip is extended, the knee may also be extended.

My routine is to check the calf and foot dorsiflexor tightness by dorsiflexing and plantar flexing the ankle respectively. Next, the hamstring group is examined with straight leg raising to 90 degrees with the patient in the supine position. The anterior thigh group is checked by attempting to put the heel to buttocks with the child in the prone position. Back tightness is demonstrated by attempting to put the forehead on the knees, with the patient's legs hanging over the edge of the bed. Most normal children can accomplish these flexibility tests easily. An exception to this generalization is the neonatal infant, who retains hip and knee tightness for four to six weeks after birth.[3]

The upper extremities are examined for muscle tightness in three areas. The shoulder adductors are tested by placing the arm over the head, the elbow extensors and flexors by flexing and extending the elbow, respectively, and the wrist and finger flexors by extending the wrist and finger simultaneously.

Testing Muscle Weakness

In order to understand why certain maneuvers are used to evaluate muscle weakness in infants, it is first necessary to review briefly conventional muscle grading.

In muscle testing several grades are used to indicate the degree of weakness. One common system is as follows: normal, moves through full range against considerable resistance; good, moves through full range against resistance; fair, moves through full range against gravity only; poor, moves through full range with gravity removed (i. e., weight of the part is supported); trace, tendon moves but no joint motion; and, lastly, zero, no function visible or palpable.

Corresponding systems are 100%, 75, 50, 25, 10, 0; 5,4,3,2,1,0; and 0,1,2,3,4,5. The latter two are exactly opposite, one grading strength in reducing order and the other grading weakness in increasing severity. The system used at this hospital is the percentage grade. It has the disadvantage of implying accuracy. However, the first mentioned has the disadvantage of use of adjectives which are commonly used in describing physical findings without a specific meaning. Use of the letters N, G, F, P, Tr, and O removes this objection. The other two grading systems are confusing, since they are exactly opposite.

In all of the above methods there are two, admittedly arbitrary, but convenient reference points: first, zero or no function and, second, enough function to move the part against gravity. For example, the grade for the function of the quadriceps if it extends the knee can be said to be fair, 50%, or 3. Function in this muscle can also be said to be "antigravity" or "gravity plus." Conventionally, this middle grade is used only with the proximal limb muscles and the trunk muscles, since the distal groups move such small and therefore light parts of the body. In the distal groups of the extremity, function is noted and can be grossly estimated by the tension of the appropriate tendon.

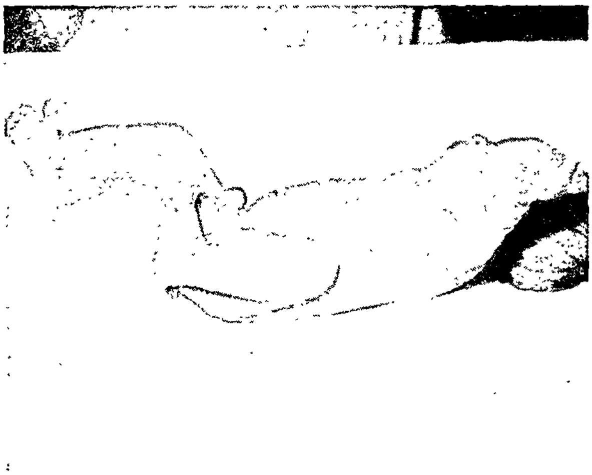

Fig. 1.—Moro embrace reflex. Note that lower extremities participate also.

Cooperation is always relative. In infants and small children the child developmentalist can, with time and persistence, usually elicit a desired activity. However, in a busy physician's office, it is more practical to consider this age group as relatively uncooperative and proceed with maneuvers to obtain desired muscle function in the shortest possible time.

When testing muscle groups in children below the age of cooperation, usually 3 or 4 years, it is most useful to divide them into two categories: those who cannot walk and those who can walk. The former includes infants who have not yet reached that stage of motor development and those older children who by reason of disease or injury cannot walk.

The reason for this division is that walking gives considerable information about muscle function in the lower extremities, the trunk, and, surprisingly enough, the upper extremities. Also, walking can be generally stimulated regardless of cooperation. Byers[4] suggested that often muscle abnormalities were first noted when the child began to walk. This is a common occurrence in my experience. Therefore, in infants and small children who cannot walk it is necessary to elicit muscle function in other ways.

Examination of the Infant

Two steps are apparent in order to examine muscle groups of infants. First, it is necessary to position the infant so that the muscle group being tested can lift the appropriate part of the body against gravity, and, second, the muscle group must be made to contract. This latter step may be difficult. Sometimes the infant will spontaneously move the part desired. In fact, some of the textbooks[5] suggest that many diagnoses of motor weakness can be made by an experienced pediatrician's observation of an infant's activity. Most of the waking time of newborn infants is spent in constant activity. Relative weakness of an extremity may be detected by observing reduced activity. In the older infant the time factor often precludes this approach, since desired function probably will not appear spontaneously.

During the first quarter of the first year of life, most of the activity is reflex in nature. Therefore, it is usually necessary to use reflexes to elicit the desired muscle function in the infant up to 3 or 4 months of age. I routinely examine for the following reflexes[6]:

First, the tonic neck reflex is present at birth and disappears at about 4 months of age. When the head is turned to the side, the arm and leg extend on that side and the arm and leg flex on the opposite side. This is used to elicit knee and elbow flexion and extension.

Second, the grasp reflex is present at birth and disappears at about 4 months of age. The infant's fingers will tighten around an object placed in them. This can demonstrate finger flexion weakness, as in Klumpke's paralysis.

Third, Landau's reflex appears from 6 to 12 months of age and disappears at about 3 years. When the infant is held in the prone position, the head, trunk, and legs extend. This is useful in detecting weakness of the hip extensors and the neck and trunk extensors.

Fourth, the Moro embrace reflex[7] is present at birth and disappears by 4 months of age (fig. 1). When the table on each side of a supine infant is struck with the hands, the infant's arms are thrown out in an embrace attitude describing an arc and tending to approach one another with a tremor. Fingers at first extend and then clench. Similar, though less marked movements, occur with the lower extremities. It becomes asymmetrical when there is weakness of one extremity, as in birth injury with laceration of peripheral nerve (Erb's palsy).

The character of the deep tendon reflexes is occasionally helpful in directing attention to muscle weakness; however, the responses are variable in newborn infants because of the motor activity.[8] The order of their appearance after birth is also variable.

Voluntary motor activity in the infant appears in a cephalocaudal manner. It is useful to simplify the motor development of the first year of life by quarters. In the first three months the infant controls his eyes, in the second three months his head and arms, in the third three months his trunk and hands, and in the last three months his legs, feet, and thumb opposition. Familiarity with developmental patterns is necessary for two reasons. First, voluntary motor activity is used in assessing muscle weakness, and, second, delay in motor development may represent the first sign of weakness.

When activity is present, either spontaneous or elicited, relative weakness of an extremity can be discovered by either of two maneuvers. The one I use most commonly is that of superimposing rapid alternating passive movements on the spontaneous activity, for example, extending and flexing the legs alternately (fig. 2). The weak extremity will resist this movement with less force. Another method is to restrain the spontaneous activity of an extremity and note the force tending to continue the motion.

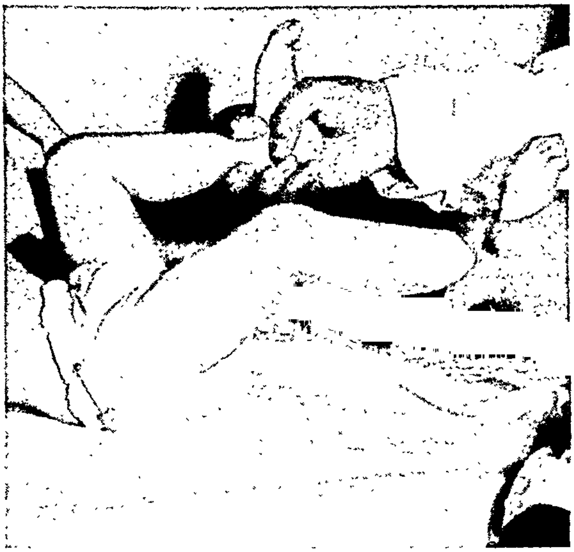

Fig. 2.—Superimposing rapid passive alternating motions on infant's lower extremities. Resistance to such motion is noted in determination of muscle weakness.

If the motor activity is not present spontaneously and has not been elicited by the techniques thus far mentioned, then noxious stimuli are used. For example, pinching an extremity with the infant supine or prone, depending on the group to be tested, will usually result in a withdrawal movement which will demonstrate function in the appropriate muscle group. When one desires to test function in the triceps and deltoid, it is useful to position the forearm and hand so that it will drop on the face. This will usually cause extension at the shoulder and the elbow and can easily demonstrate weakness in these groups. Often, placing a corner of the sheet over the infant's face will result in function of the upper extremities, either reflex or voluntary, to attempt removal.

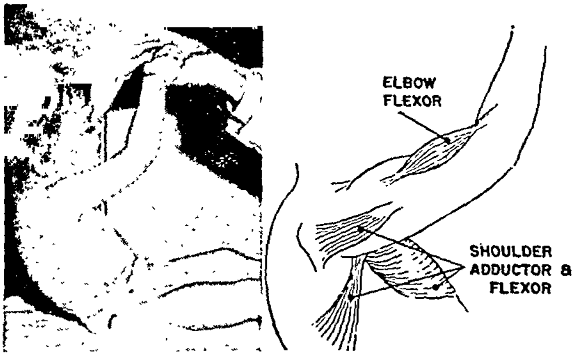

Fig. 3.—Knop test, showing supine infant being pulled to sitting position.

Stroking the sole of the forefoot will cause dorsiflexion of the foot; stroking the heel will cause plantar flexion. With the infant in the prone position and the lower extremities hanging over the edge of the examining table, stroking of the posterior thigh and buttocks will cause the hip to extend, as well as the knee to flex.

I also make the Knop test[9] (fig. 3) a regular part of the examination of each infant. With the infant supine, the hands are grasped and the baby is pulled to the sitting position. The degree of head lag and the attitude of the shoulders and the elbows give clues about arm and neck weakness. Next, the feet are grasped and the buttocks lifted off the table to elicit hip and knee weakness. Although Knop used this to describe the newborn infant's dynamics, it is useful in older infants and children and has been a part of the neurological examination for many years. If there is a head lag after the infant is 4 or 5 months of age, it is suggestive of weakness of the neck flexors or other pathological states resulting in hypotonia of this muscle group. If there is muscle weakness of one leg or arm, that extremity will straighten while the normal extremity will flex at the knee and hip when the lower extremities are lifted.

The shoulder adductors and the scapular stabilizers can also be tested by lifting the infant or child under the armpits with the fingers extended. When these groups are weak or hypotonic, the patient will slide through the examiner's hands. To make this test more sensitive, the infant is gently tossed in the air a few inches and caught in this position.

Chaney and McGraw[6] found that almost one-third of newborn infants would bear weight on the lower extremities when held in the erect position. A similar proportion demonstrated crawling motions when held in the prone position. Perlstein and Barnett[10] noted that reciprocal motions of the lower extremities are present by 2 to 3 months of age at the latest when the infant is held in the erect position (fig. 4). These motor activities can often guide the examiner to discovery of muscle weakness of the lower extremities. Thus, in the space of a few moments, the infant can be pulled to a sitting position, held in erect position, tossed and caught under the armpits, and suspended in the prone position for a fair estimation of the general muscle strength. When the examiner's attention is directed to a possible area of weakness, specific muscle function can be elicited.

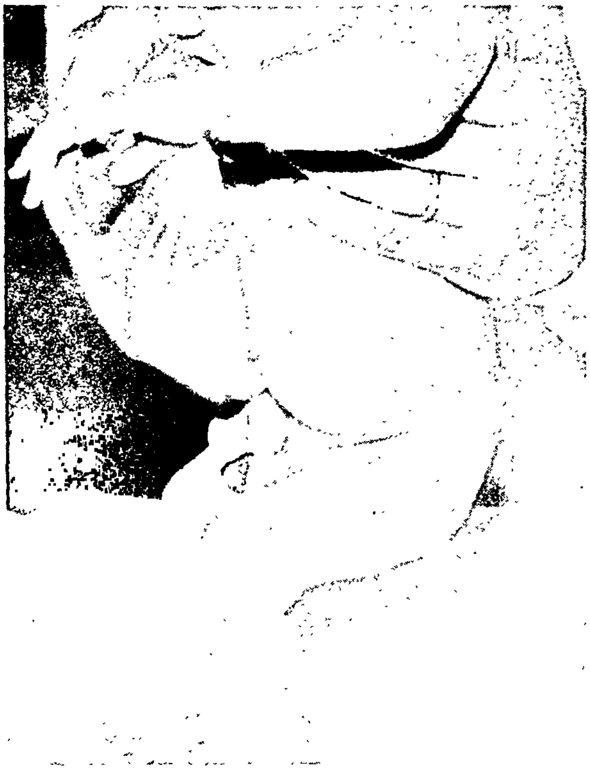

Fig. 4.—Infant held erect to demonstrate reciprocal motions of legs. Infant shown was 4 days old.

Observing spontaneous activity, eliciting reflex activity, understanding normal motor development, and using ingenuity to stimulate specific groups provide a systematic approach to detecting muscle weakness in children under one year of age.

Examination of the Walking Child

Active walking is associated with considerable muscle activity, so that muscle weakness in the trunk and lower extremities can be discerned. Although the gait pattern is not stabilized until about the age of 7, the requirements of maintaining an erect posture over two moving extremities are such that careful analysis of the child's gait pattern will provide clues about muscle weakness. If the gait appears relatively normal, the child can be made to walk on his toes and on his heels and then run and hop, squat, and stand up to bring out less apparent difficulties. The child of 2 years can run after a fashion and at 3 years runs well, but he usually cannot hop until 4½ years of age.

The walking base of the small child is often mentioned during the neurological examination. This is the distance between the medial edge of the heels when they are in the same frontal plane. Such descriptions as wide and narrow are applied to the base without really specific values in mind. There are factors which alter the width of the base other than neurological factors, for example, the angle between tibia and femur and the femoral neck angle. Generally, a wide base, more than 3 or 4 in. if there is no genu valgum, points to genuine instability in a child who has walked for four to six months.

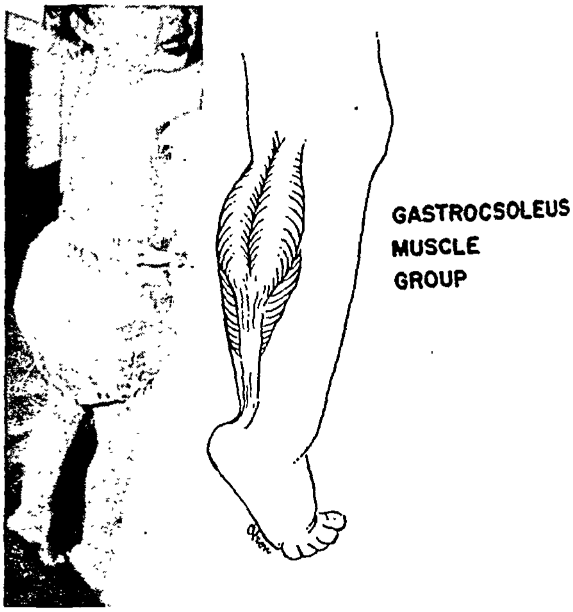

Fig. 5.—Standing on toes to demonstrate function of gastroc-soleus group.

If the child is taken from his parents and set on the floor 10 or 15 ft. away, he will usually rise to the standing position, run to his parent, there rise on his toes, and reach with his arms outstretched. This provides a good estimation of the strength of the proximal groups of the lower extremities as he stands and of the proximal groups of the upper extremities and the gastrocnemius-soleus groups when he reaches his parents. If the parent is not present, the same result can be easily accomplished by taking the child away from his bed (fig. 5).

If it is impossible to get the child to walk on his heels, the foot groups are tested by stroking the sole of his forefoot, or, in the standing position, if the patient is distracted in the opposite direction of the pull of the muscle group to be tested, the muscle will contract in an attempt to regain balance. This is done with a finger over the tendon, which immediately tenses as the appropriate muscle contracts. Groups which can be tested with this technique are the "guy wire" muscles of the feet, that is, posterior tibial, anterior tibial, peroneal, and gastrocnemius-soleus.

Holding the child with the examiner's arm around the upper thighs and allowing the patient to jack-knife forward and then extend his head and trunk will give a good estimate of the neck, back, and hip extensors (fig. 6). This, in effect, is using the Landau reflex.

Abdominal muscles are best tested by sit-ups. It has been recognized for some time that a child cannot come to the sitting position when lying supine without using hands until the age of 4 or 5. In my experience, 4 years has been the average age. I believe that this is related to the migration of the center of gravity of the body, which at about the age of 5 passes caudal to the umbilicus.[11] This means that until this age more than 50% of the body weight is above the axis around which the trunk flexors act, putting them at considerable disadvantage. To insure maximum effort in the sit-up test it is helpful to assist the child by pulling on a few strands of hair as he attempts to come to the sitting position.

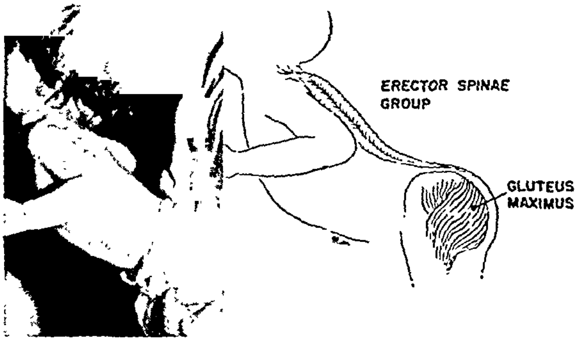

Fig. 6.—Holding child by thighs to demonstrate trunk and hip extensor function.

In the cooperative child, it has been a constant observation that, when instructed to hold the part against the examiner's resistance, if there is true muscle weakness present he will assist with an uninvolved extremity, either hand or leg.

As the examination is concluded, dressing techniques are used to elicit muscle function previously unobtained or to verify earlier observations. The relieved young child will often cooperate quite well in raising his arms to put on a blouse, shirt, or coat held rather high (fig. 7). This can demonstrate antigravity function of the proximal upper extremity muscles. He will often bear his weight well on one leg as his pants are put on and raise his leg and foot for socks and shoes.

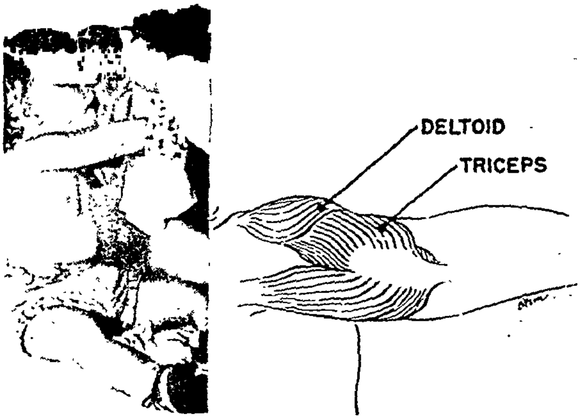

Fig. 7.—Dressing technique to demonstrate triceps and deltoid function.

No mention has been made thus far about the importance of the history. On several occasions during the past year I have been asked to see small children who, their parents insist, fall frequently or behave abnormally in terms of motor development. Although I have been unable to demonstrate clinical weakness, I always believe the parent and go to the laboratory for objective assistance in detecting disease of the motor unit.

Electromyographic Examination

The most sensitive method to date of detecting abnormalities of the motor unit is the electromyographic examination. The electromyograph is composed of an electrode system, an amplifier, an oscilloscope, a loud-speaker, and a storing device, such as a camera or tape recorder (fig. 8). It picks up, amplifies, and indicates the action potential of the muscle fiber. This is the electrical activity immediately preceding the contraction.

A group of muscle fibers numbering from a few to 1,000 or more, depending on the muscle, together with the lower motor neuron is termed the motor unit. The summation of the action potentials of the muscle fibers comprising the motor unit is viewed on the oscilloscope and heard over the loud-speaker as a motor unit action potential. Disease or injury of the motor unit alters the pattern of voltages picked up by the electromyograph.

Diagnostic potentials in the various clinical conditions affecting the motor unit are present when the muscle is at rest, as well as when the muscle is active. Thus, a similar situation to the clinical examination exists in the electromyographic examination. First, the voltages must be noted when the muscle is at rest, at both insertional and spontaneous activity, and then when it is active, at both minimal and maximal contraction. Techniques to obtain specific muscle group activity have been described, but it is a most difficult problem to obtain muscle relaxation in an infant or small child. This is especially difficult in a newborn infant in the waking state. This also presents a problem when the child is in the uncooperative age, that is, between 1 and 3½ or 4 years of age, when the child is easily frightened and upset in a strange environment. The procedure itself is associated with a minor amount of discomfort; however, the semidarkened room and the noises over the loud-speaker often serve to disturb the small child even more. In general, the most satisfactory examinations are done in children under 1 and over 4 years of age. In the latter age group they are usually old enough to understand and follow instructions. In preparing the child for the examination, it is suggested to them that they "will see their muscles on television." A simultaneous pinch or slap with insertion of the needle electrode will usually allow the insertion to pass unnoticed. The presence of a parent in the room during the examination is absolutely interdicted.

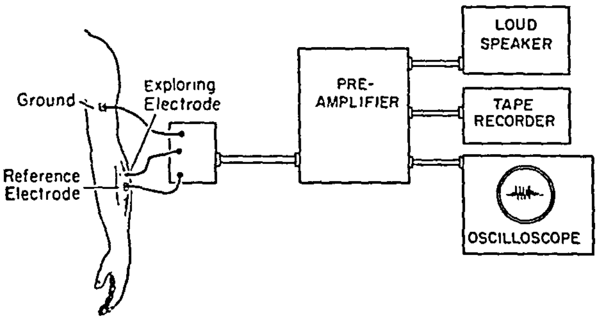

Fig. 8.—Schematic representation of components of electromyograph.

The approach I use to the electromyographic examination in an infant or an uncooperative small child is to examine first muscles which are inactive, usually, for example, the intrinsic muscles of the hands and feet, that is, extensor digitorum brevis, abductor digiti quinti pedis, opponens, hypothenar eminence, and first dorsal interosseus. The opponens is generally not active voluntarily until the child is 36 to 38 weeks of age.

Second, the muscle to be examined is positioned in a most unfavorable position for activity. This is usually, but not always, in its shortest length. In examination of the anterior tibial, dorsiflexion of the foot to an extreme degree will often discourage muscle contraction (fig. 9). Conversely, the long head of the triceps is usually not active with the elbow flexed to more than 120 degrees.

As was mentioned previously, most of the difficulty is with children from the ages of 1 to 4 years. Here it is felt that sedation is occasionally helpful; however, if used too heavily, one is unable to obtain maximum contraction, and, if it is used in smaller dosages, the child will become aroused after one or two muscles have been investigated. During the past year, with an average of 50 electromyographic examinations each month, of which at least half were in children, it has been found necessary to use sedation in only two instances. Once an electromyographic abnormality is demonstrated, the next problem is to determine the distribution of that abnormality. This requires investigation of muscles other than those mentioned earlier, so that the examiner's patience and ingenuity is tested.

An additional determination which adds another dimension to electromyography is the measurement of the nerve conduction velocity. This is helpful in localizing diseases of the motor unit to the axon of the lower motor neuron. It is the stimulation of the motor nerve at two locations along its course, photographing the stimulus artifact and the muscle response with an appropriate time base. After the distance on the skin between two points of stimulation is measured, counting the time base between stimulus artifact and the muscle response on the photograph, the nerve conduction velocity is calculated in meters per second. This is usually reduced in chronic diseases affecting the axon, such as infectious neuronitis, regenerating injured peripheral nerves, and polyneuritides of various types. The nerves most accessible for this study are the ulnar and median nerves in the forearm and the common

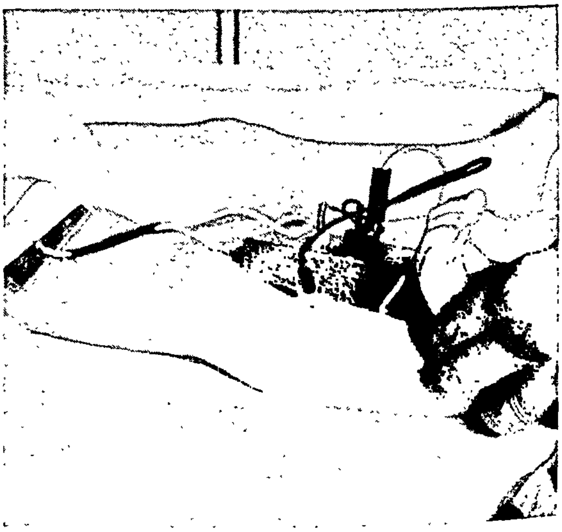

Fig. 9.—Foot in passive dorsiflexion to discourage voluntary activity of anterior tibial. Note position of needle electrode and ground.

peroneal nerve and posterior tibial in the leg. In these nerves the conduction velocity varies from 45-70 meters per second in the adult. The conduction velocity of newborn infants is reduced[12] and does not approach the adult standards until the child is 3 or 4 years of age.

The accurate clinical determination of muscle weakness in an infant or uncooperative small child is of paramount importance in the proper diagnosis of diseases of the motor unit. If the history or examination suggests weakness which cannot be localized clinically, the electromyographic examination can prove very helpful. The following case illustrates this point.

A 3-year-old boy was admitted to Children's Hospital in November, 1957, with a chief complaint of "not walking right." For several months he had been complaining of stiffness and soreness of his muscles without a clear-cut febrile illness. Physicians, including a neurologist, pediatrician, orthopedist, and internist, had entertained diagnoses from poliomyelitis to no disease present. Physical examination demonstrated mild generalized symmetrical weakness with function of the proximal limb muscles rated as barely "antigravity." Palpation of muscle bellies suggested increased resistance and elicited moderate tenderness. The electromyogram showed small, short, duration potentials with increased proportion of polyphasic potentials and many fibrillation potentials. This was interpreted as most suggestive of polymyositis. The serum transaminase level was within the upper limits of normal. Muscle biopsy showed degenerative muscle fibers with round cell infiltration. When reexamined in six months, he had developed characteristic skin lesions of dermatomyositis.

Summary

The detection of muscle weakness in infants and small children depends on three principles: (1) understanding the normal motor developmental pattern of infants, (2) knowing functional anatomy, and (3) developing techniques to elicit specific muscle group activity.

Using these three approaches, any physician dealing with this age group can become surprisingly adept in the diagnosis of muscle weakness. When the clinical examination suggests weakness or the physician suspects a disease or injury of the motor unit in the absence of physical findings, the most sensitive method of detecting and localizing such pathology used to date is the electromyographic examination.

STRESS AND DIABETES.—On clinical, statistical and experimental evidence all forms of stress play an important part in the disturbance of good control in diabetes. The effect of emotional stress, usually anxiety, is apparent in the older group of mild, obese, insulin-resistant cases. In the younger group of acute, thin, insulin-sensitive diabetics, stress due to associated endocrine imbalance is more common. It is probable that emotional stress is never the sole etiological agent in diabetes, but may have an additive or precipitating effect. As no single diabetogenic hormone has yet been isolated it is assumed that the mechanism is under hypothalamic control and may be in the nature of an overflow from adrenocorticotropic, gonadotropic and thyrotropic hormones stimulating the growth hormone. . . . Attention is drawn to the association of the premenstrual syndrome, stress, and fluctuation in diabetic control. Recurrent coma seems to occur in individuals of poor moral stamina and inadequate personality who, on one pretext or another, omit their insulin and lapse into coma to avoid an unpleasant life situation. A plea is made for the management of certain categories of diabetics in special units where the staff can become interested and competent to care for them in such a way as to give maximum security, education and encouragement.—J. B. Walker, M.D., Stress and Diabetes. *The Practitioner,* May, 1957.

TREATMENT OF THROMBOSIS WITH FIBRINOLYSIN (PLASMIN)

Joseph E. Sokal, M.D., Julian L. Ambrus, M.D., Ph.D.
and
Clara M. Ambrus, M.D., Ph.D., Buffalo

The possibility of dissolving a recent thrombus by the intravenous administration of a fibrinolytic enzyme was studied in a series of patients. Fibrinolysin (plasmin) was prepared in several ways from human and bovine plasma, and preparations were obtained from other laboratories also. Altogether 114 infusions of fibrinolysin were given to 37 volunteer patients, most of whom had incurable cancer. Thirteen episodes of acute thrombophlebitis, occurring in 10 patients of this series, were treated. In five of the eight cases in which the age of the thrombus was three days or less, complete resolution was obtained. When improvement did occur, the pattern of response was fairly uniform; pain was relieved within 24 hours, color improved and tenderness disappeared shortly thereafter, and edema disappeared within a few days. The results, which were sometimes striking, are illustrated in 14 case histories. Fibrinolysin was ineffective when given a week or more after the first manifestations of thrombosis, and it did not prevent the formation of fresh thrombi. The mechanism of its action upon blood clots in vitro as well as the clinical experiences here reported argue in favor of simultaneous administration of anticoagulants with fibrinolysin in the management of acute thromboses.

Arterial and venous thromboses are a major cause of morbidity and mortality. Much has been accomplished in recent years to lessen the toll of thrombotic diseases through the use of anticoagulant therapy, often continued for years or for life, in patients who have had serious thrombotic episodes. However, anticoagulant therapy serves only to prevent further thrombotic complications; it does not remove clots which have already formed. Several attempts have been made to treat acute thromboses with agents that showed promise of dissolving existing thrombi. Potent proteolytic enzymes, such as trypsin and chymotrypsin, have been administered locally or systemically to patients suffering from vascular thromboses or from diseases characterized by undesirable fibrin deposition.[1] Although the local administration of such enzymes is widely practiced, systemic use has not met with general acceptance. In addition to such hazards as sensitization to foreign protein and the severe side-reactions which may follow systemic administration in adequate doses, the lack of specificity of these enzymes is a serious disadvantage. Studies in this laboratory indicated that systemic doses of trypsin, chymotrypsin, crude pancreatic protease, papain, and ficin, sufficient to produce intravascular lysis of experimental clots in dogs, also produced falls in the levels of several proteins involved in the blood clotting system, occasionally resulting in fatal hemorrhage.[2] Only preparations of fibrinolysin (plasmin) were able to lyse venous or arterial clots at nontoxic concentrations.

Fibrinolysin is a proteolytic enzyme which manifests selective affinity for fibrin as a substrate.[3] Its physiological role is believed to be the lysis of the fibrin deposits in blood vessels and tissues which result from the minor injuries and spontaneous thromboses of everyday life.[3c] Many excellent reviews dealing with fibrinolysin have appeared in recent years.[4] The following account is a somewhat simplified summary of our present knowledge of this important biological agent.

Fibrinolysin absorbs selectively to fibrin and hydrolyzes it into smaller soluble fragments. Free fibrinolysin is not normally found in the blood. A precursor, profibrinolysin (plasminogen) is a normal constituent of the plasma. Profibrinolysin is transformed to fibrinolysin by a number of activators found in tissues and in various secretions (urine, tears, milk, saliva, and seminal fluid). In the latter areas, profibrinolysin activators may play a physiological role in keeping narrow channels of excretion open. Tissue activators may appear in the circulation during stress, muscular exercise, and hypoxia and after epinephrine injections. Blood also contains an antifibrinolysin factor which can rapidly neutralize fibrinolysin.

The physiological relationship of clotting mechanisms to the fibrinolytic system is illustrated in figure 1. When tissues are damaged, thromboplastin is liberated and the complex mechanism of clotting, leading to fibrin deposition, is initiated. Fibrin promotes hemostasis and forms a matrix for reparative processes. Profibrinolysin (plasminogen) activators are also released at the injured site. Circulating profibrinolysin is locally converted into fibrinolysin, binds to the fibrin fibers, and dissolves

---

From the Roswell Park Memorial Institute and the University of Buffalo Medical School.

them after a period of time. Thus, repair can proceed without scar formation. Circulating antifibrinolysin binds and inactivates any excess of free fibrinolysin in the circulation.

In some disease states, notably, carcinoma of the prostate, large amounts of free fibrinolysin appear in the blood and lead to a hemorrhagic diathesis. On the other hand, we have seen some patients who suffered from repeated thromboses and were found to have very high levels of circulating antifibrinolysin. Deficiencies in the fibrinolytic system were recently implicated in the development of atherosclerotic lesions on the basis of excessive fibrin deposits in the intima.[3c]

Human profibrinolysin is obtained as a product of blood plasma fractionation. It can be activated artificially in several ways. A potent activator is bacterial streptokinase. Almost as potent is the enzyme urokinase, derived from human urine. Spontaneous conversion of profibrinolysin to fibrinolysin takes place under certain physical and chemical conditions; however, this is an inefficient way to prepare fibrinolysin. Bovine fibrinolysin can be produced by activation with chloroform. The physical and biochemical properties of fibrinolysin vary somewhat with different methods of activation and preparation.[5]

We have investigated various methods of preparation and purification of fibrinolysin, starting with crude profibrinolysin fractions obtained from pooled human or bovine plasma. Changes in preparative technique have resulted in major alterations in the fibrinolytic activity of the final product. In some cases we encountered considerable variation in potency from batch to batch, even when the same technique of preparation was used. In general, however, we have been able to produce fibrinolysin of satisfactory potency by several different methods. A number of preparations were obtained from other investigators. A large number of different preparations were tested in animals for in vivo fibrinolytic activity. These studies have been reported in detail.[2b] A brief summary follows: Radioactive arterial and venous clots were produced in dogs, rabbits, and monkeys. Semiconstricting ligatures were left in place to prevent dislodgment of the clots. The fate of the clots was followed in several ways—by continuous recording of radioactivity over vessel segments containing the clots, by phlebography with iodopyracet (Diodrast), and, in some cases, by direct visualization. Control clots remained in place satisfactorily and showed only slight declines in radioactivity over periods of seven days. Although the vessels remained effectively obstructed, small amounts of iodopyracet were seen to pass the

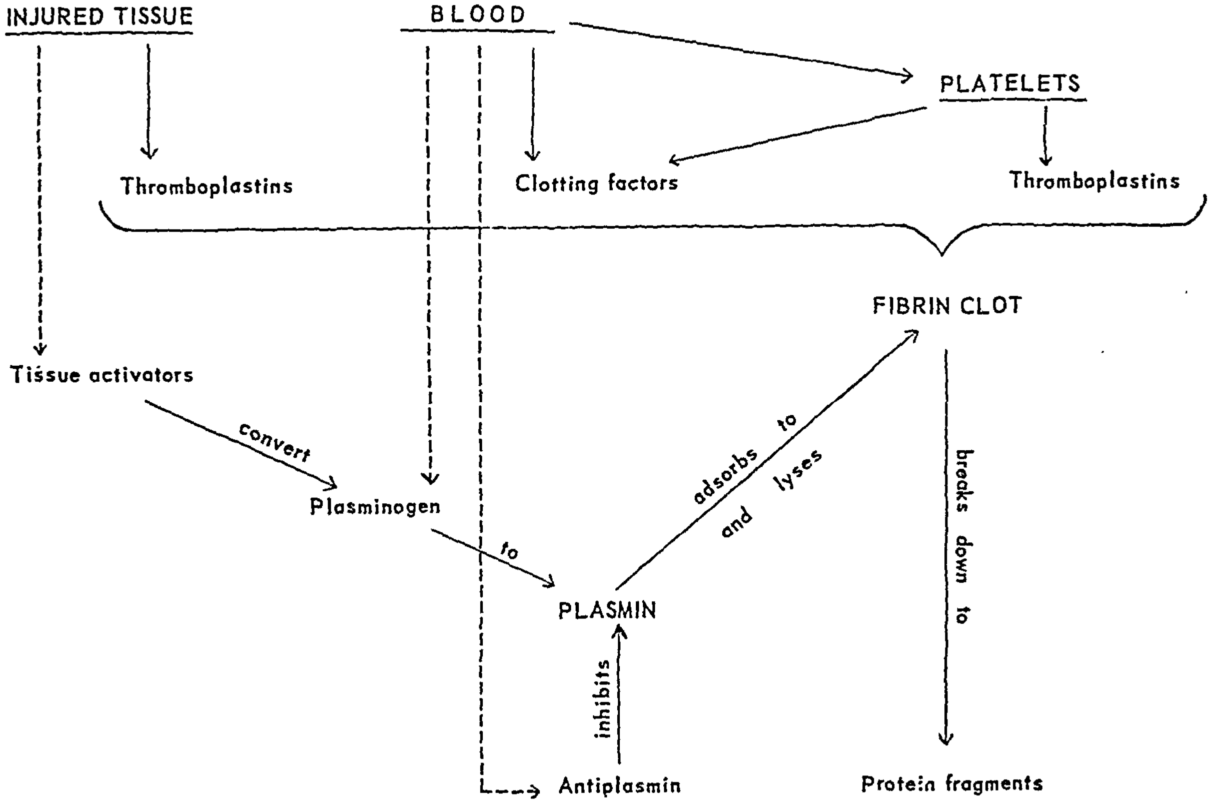

Fig. 1.—Simplified diagram of relationship between blood clotting and fibrinolytic systems.

thrombosed segments, indicating that the fibrin meshwork did not completely block blood flow and that intravenously administered agents may be able to permeate the interstices of a fresh clot. Serial histological studies of clots induced in dogs showed beginning endothelialization and organization of clots at three days, proceeding rapidly thereafter.[6] Fibrinolysin was infused intravenously at a distant site at various time intervals after the formation of radioactive clots in dogs. When the interval between formation of the clot and administration of fibrinolysin was 72 hours or less, clot lysis was observed in most experiments. This was demonstrated by decrease or disappearance of radioactivity over the vessel segment, by phlebographic visualization of open vascular segments, and, in superficial clots, by direct observation. Clots three days of age or older showed only partial or no lysis.[7] Acute and subacute pharmacological studies in mice, guinea pigs, rabbits, dogs, and monkeys were performed with various potent preparations of fibrinolysin. With most preparations no significant toxic manifestations were observed at dosage levels considerably in excess of those required to produce in vivo clot lysis. Most preparations were nonpyrogenic for rabbits.

On the basis of these animal experiments, several fibrinolysin preparations were selected for trial in man. The patients used were volunteers, most of whom had incurable cancer. The principal indications for therapy were acute and subacute peripheral thromboses and certain edematous states. Since one of the principal purposes of this study was to compare the side-effects of various preparations, patients were accepted for treatment even though the diagnosis was questionable. Such cases are excluded from the therapeutic evaluation, however. In most cases, two or more different preparations were administered during a course of therapy.

Methods

Diagnosis and Evaluation of Therapeutic Effect.—Standard criteria for the diagnosis of thrombophlebitis were used. Most patients gave typical clinical histories of pain and swelling of an extremity developing rapidly over a period of a few hours to two days. A few bedridden patients were observed to have developed edema and cyanosis of a leg overnight without spontaneous pain. In cases of superficial thrombophlebitis, typical signs of inflammatory reaction over the involved veins were observed. In such cases, thrombosed veins could be palpated easily. All patients had tenderness over the involved area. Homans' sign was positive in patients with deep thrombophlebitis of the calf. Lowenberg's cuff test[8] was used as a quantitative measure of compression tenderness. In a few cases, venous occlusion was demonstrated by contrast venography. The age of the thrombophlebitis was estimated from the clinical history. Onset was dated from the first definite symptoms or signs.

Serial observations of the following points were carried out on all patients diagnosed as having thrombophlebitis: evaluation of symptoms, presence of Homans' sign, results of Lowenberg's cuff test, circumference of extremity at several points, degree of edema, intensity of cyanosis, and degree of visible inflammatory reaction. A typical clinical progress sheet is discussed below. In some cases, skin temperature recordings were obtained at several points. Evaluation of therapeutic response was based on these observations. In one case, reopening of major venous channels was demonstrated by venography. No patient is listed as having a "complete resolution" unless the signs and symptoms of thrombophlebitis disappeared within one week of the beginning of therapy. Patients were classified as "improved" if marked resolution by most criteria occurred within one week but some abnormalities persisted.

Arterial occlusion was diagnosed by the typical history of rapidly developing pain, coldness and discoloration in an extremity associated with the characteristic findings of pallor or mottling, and absent arterial pulses below the point of occlusion. The diagnosis was confirmed by determination of skin oxygen tension before and after inhalation of pure oxygen.[9] The application of this method is illustrated below.

Other diagnoses were made by the usual clinical criteria and require no detailed discussion here. In all cases, patients were examined by two or more physicians not associated with this project and the diagnoses under which patients are classified were unanimously agreed on.

Additional Clinical and Laboratory Observations.—Before, during, and after fibrinolysin infusions determinations were obtained of blood pressure, pulse rate, respiration rate, temperature, electrocardiographic tracing, basal metabolic rate, hemoglobin level, hematocrit value, white blood cell, platelet, and differential counts, blood fibrinolysin, profibrinolysin, and antifibrinolysin levels,[2b] fibrinogen level, prothrombin time, and Lee-White coagulation time. In some cases more detailed study of factors of the blood clotting system was undertaken.

Fibrinolysin Preparations.—The fibrinolysin preparations used in this study were of five general types, as follows: (*a*) human profibrinolysin prepared from pooled plasma obtained from the American Red Cross Blood Program, activated with an excess of crude streptokinase (Varidase or Streptokinase); (*b*) various purified fractions of the above, from which much material of streptococcic origin had been removed; (*c*) human profibrinolysin activated with human urokinase; (*d*) human profibrinolysin allowed to activate spontaneously; and (*e*) bovine profibrinolysin activated with chloroform. Details of the methods of preparation of these fractions and their individual characteristics will be presented elsewhere.[10]

Fibrinolysin was administered by intravenous infusion over a two-to-four-hour period. The usual dose was 15 Loomis units [11] per kilogram of body weight, administered in 500 to 1,000 ml. of saline solution. All preparations of fibrinolysin were found to lose activity rapidly at room temperature. Infusion bottles were therefore placed in a refrigerated holder.

Results

A total of 114 infusions of fibrinolysin was given to 37 patients. Side-reactions to these infusions varied greatly, depending on the preparation used. There was also moderate variation among different patients receiving the same preparation.

The worst side-reactions were induced by preparations containing an excess of crude streptokinase. Malaise, nausea, tachycardia, and cutaneous vasoconstriction were the initial manifestations of these reactions and appeared about one to two hours after the beginning of the infusion. Elevation of the basal metabolic rate was noted at this time. Soon afterward, one or more shaking chills occurred, followed by fever. The basal metabolic rate rose as much as 150%. Premedication with antipyretics, analgesics, chlorpromazine, and antihistamines reduced the intensity of these reactions but did not abolish them. Intravenously given amobarbital sodium (sodium Amytal) or thiopental (Pentothal) sodium, administered during the premonitory stage of malaise in doses sufficient to induce sleep, completely prevented the chills and reversed the cutaneous vasoconstriction. This medication was effective in arresting chills even when given during the height of these reactions. However, the elevation of metabolic rate and the height of the temperature were not affected by these hypnotics, even though muscular contractions and heat conservation by the skin were blocked. Increase in blood pressure was noted during the early stages of these severe reactions and was sometimes followed by hypotensive episodes two to six hours after the infusion. In a few patients, electrocardiographic changes were observed during the height of the reaction. Recovery from these side-reactions was complete within 2 to 12 hours.

Variation of the methods of preparation and of the activators used resulted in a series of preparations with decreased toxicity. Finally, two human fibrinolysin preparations were obtained which produced slight or no side-effects. One of these was a purified, streptokinase-activated preparation; the other was activated with urokinase. Even the nontoxic streptokinase-activated preparations were antigenic and resulted in the production of antistreptokinase antibodies and skin sensitivity to crude streptokinase. The urokinase-activated preparation did not induce antibody production or skin sensitivity.

Spontaneously activated human fibrinolysin and chloroform-activated bovine fibrinolysin caused few or no side-reactions. However, these preparations appeared to be less effective than the streptokinase-activated or urokinase-activated human preparations.

The therapeutic results in 26 episodes suitable for evaluation are discussed below.

Peripheral Thrombophlebitis.—Thirteen episodes of acute thrombophlebitis, occurring in 10 patients, were treated. In addition to fibrinolysin therapy, standard nursing procedures and conservative symptomatic therapy were employed, including bed rest, a cradle to lift bed covers over the affected extremities, analgesics, sedatives, and other treatments. In seven instances, anticoagulant therapy was withheld until fibrinolysin treatment and evaluation of the response was completed. Antibiotics were administered in one case. The age of the thrombotic processes at the time of institution of therapy was one day or less in six instances, 2 to 3 days in two instances, 4 to 5 days in four instances, and 10 days in one.

Table 1 presents the therapeutic response in these cases. Complete resolution was obtained in five of the eight instances where the age of the process was three days or less, and definite improvement was seen in one other. Among the older processes, complete resolution was seen in one, improvement in two, and no effect in two. The pattern of response was relatively uniform in the cases where improvement was observed. Pain was relieved rapidly and usually disappeared within the first 24 hours. Color changes and tenderness to pressure were the next to respond. Resolution of edema took longer and was sometimes incomplete several days after all other signs had disappeared. Since most of these patients had disseminated intra-abdominal cancer, however, it is difficult to evaluate the significance of the slow clearing of edema. Partial obstruction of pelvic and abdominal veins and lymphatics may have been the principal reason for the slow response in many of these cases. Individual case reports follow:

Case 1.—A 34-year-old woman with far-advanced carcinoma of the stomach and intreperitoneal dissemination developed acute thrombophlebitis of the left leg. The leg was obviously swollen and cyanotic; distended superficial veins could be seen. Homans' sign and the cuff compression test were strongly positive. Fibrinolysin therapy was started about 24 hours after onset of thrombophlebitis. She had moderately severe side-reactions to the first infusion, with malaise, chills, temperature of 103.2 F (39.5 C), and basal metabolic rate of +117%, in spite of premedication with 0.6 Gm. of aminopyrine and 50 mg. of chlorpromazine. On the following morning the color of the left leg was almost normal. Homans' sign was equivocal, and there was subjective improvement. The second infusion induced a mild febrile reaction, with a maximum temperature of 101 F

(38.3 C). Rapid improvement continued. Homans' sign became negative on the third morning, and treatment was discontinued. There was still slight edema of the leg at this time. Two days later, however, the leg appeared entirely normal and there were no signs or symptoms of thrombophlebitis. Table 2 presents some of the clinical observations recorded during therapy and is illustrative of the techniques used to evaluate results in this series. The patient's general condition deteriorated rapidly, and she died a few days later. Shortly before death, signs of venous thrombosis again appeared. Autopsy revealed a fresh thrombus in the left iliac vein and pulmonary embolization.

TABLE 1.—*Clinical Course of Ten Patients with Thrombophlebitis Treated with Fibrinolysin*

Case, No.	Involvement	Age of Process, Days	No. of Fibrinolysin Infusions/Days	Other Therapy	Response, No. of Days After First Fibrinolysin Infusion: Pain-Free Motion	Color Normal	No Edema	Homans' Sign Negative	Serial Phlebograms

* Inoperable gastric carcinoma, gastric hemorrhage, and thrombophlebitis of left leg.
† End-point, report of pain by patient.

CASE 2.—A 39-year-old woman with advanced metastatic ovarian adenocarcinoma developed thrombophlebitis of the deep veins of the right leg. The process was four to five days old when she was referred to us. The leg was obviously swollen. Homans' sign and Lowenberg's cuff test were positive. Temperature was 100.6 F (38 C). Fibrinolysin was administered daily for five days. The first infusion induced mild chills, lasting about 10 minutes. There were no side-reactions to subsequent treatment. Sixteen hours after the first infusion, the patient reported that the right leg became "less tight" and she could bend it for the first time in several days. There was a slight decrease in the pressure sensitivity of the right calf. On the following day there was further decrease in pressure sensitivity and in the circumference of the right leg. Rapid improvement continued. On the fourth day, pressure sensitivities in the two legs were equal and Homans' sign was equivocal. After one week, the patient was asymptomatic and ambulatory, Homans' sign was negative, and the leg appeared normal. Anticoagulants were not administered, and the patient was discharged a week later.

Two days after discharge, the patient returned with acute thrombophlebitis of the deep veins of the left leg, of about one day's duration. The leg was edematous and highly sensitive to pressure. Homans' sign was strongly positive. Venograms were obtained by applying a tourniquet above the ankle and forcibly injecting diatrizoate (Hypaque) sodium into a superficial vein of the dorsal surface of the foot. The dye dissipated slowly and filled only the superficial veins of the leg. All deep venous channels appeared to be occluded (fig. 2A). Fibrinolysin was administered for six days, with mild reactions on two occasions. Pain subsided within 24 hours, and she was able to move the leg without difficulty. Pressure sensitivity returned to normal in two days. Homans' sign became negative after three days. The circumference of the leg decreased but did not return to the prethrombosis level. Repeat venograms, with identical technique, demonstrated reopening of the tibial vein (fig. 2B). The patient was then treated with heparin and bishydroxycoumarin and was discharged a week later on maintenance bishydroxycoumarin therapy. Two months after discharge the patient was doing well, without recurrence of thrombosis.

CASE 3.—A 72-year-old woman with agnogenic myeloid metaplasia and a history of several hemorrhagic and thrombophlebitic episodes was admitted with pain and swelling of the left leg of about 10 days' duration. Pitting edema of the leg and marked inflammatory reaction along the course of the superficial saphenous vein were noted. The thrombosed vein was palpable and exquisitely tender. Platelet count was 2,500,000 per cubic millimeter. Venography revealed occlusion of the major superficial veins, but patent deep veins. Fibrinolysin was administered for four days with one moderately severe reaction and one mild reaction. No improvement was seen; pain persisted and edema of the extremity increased. Heparin therapy was instituted, but it proved difficult to hold the clotting time within therapeutic limits; the patient appeared to require much more than the usual doses of heparin. During the following days additional areas of thrombophlebitis appeared, involving the right forearm and the left upper arm and shoulder (sites of intravenous therapy). Fibrinolysin therapy was reinstituted, and the dosage of heparin was increased. Only partial and transient improvement was noted in the superficial thrombophlebitis of the right forearm. However, the edema, tenderness, and inflammatory reaction of the left upper arm, shoulder, and anterior part of the chest resolved completely in 48 hours. Edema of the left leg and thigh increased. Fibrinolysin therapy was discontinued, but energetic anticoagulant therapy was maintained. Slow, gradual improvement in the areas of residual thrombosis occurred during the next two months.

Case 4.—A 74-year-old man with inoperable adenocarcinoma of the rectum underwent sigmoid colostomy. Nine days later he developed pain and swelling of the left calf. Homans' sign and Lowenberg's cuff test were equivocal. Venograms showed thrombosis of the posterior tibial vein and partial obstruction of the anterior tibial and femoral veins. Fibrinolysin therapy was started on the following day and continued for five days. He also received anticoagulant therapy with heparin and bishydroxycoumarin. He had a mild reaction to the third fibrinolysin infusion and a moderately severe reaction, followed by a hypotensive episode, after the fifth infusion. The leg remained swollen. Repeat venograms one week after the initial study showed progression of the thrombotic process, with extension of the femoral thrombosis. Gradual improvement in the condition of the leg occurred during the next four weeks, but some edema was still present at the time of discharge.

Case 5.—A 62-year-old man with generalized arteriosclerosis, arteriosclerotic heart disease, and carcinoma of the urethra underwent radical curative surgery and had a prolonged convalescence. One month after the operation he complained of pain in the right leg. On examination the leg was found to be warm and swollen. Homans' sign and Lowenberg's cuff test were positive. Heparin and bishydroxycoumarin were administered, and fibrinolysin therapy was started. He received four infusions of fibrinolysin on successive days, with mild reactions to the first three. Striking subjective improvement and decrease in edema were noted on the morning after the first infusion. One day later, Homans' sign became negative. Four days after the first fibrinolysin infusion, the leg was entirely normal.

Case 6.—A 74-year-old woman with carcinoma of the cervix, arteriosclerotic heart disease, and a history of bilateral thrombophlebitis of the legs and prophylactic femoral vein ligations done five years previously developed pain in the right calf. On examination one day later, she had a strongly positive Homans' sign and an inflamed, tender area on the medial aspect of the calf. She was considered to have both superficial and deep thrombophlebitis. She received two infusions of fibrinolysin, with moderately severe chills and fever after the second dose. On the morning after the first infusion, Homans' sign was negative and the area of superficial involvement was strikingly improved. By the following day, there were no residue of the acute episode.

Case 7.—A 52-year-old woman was intermittently treated with radiation for 10 years in another hospital for lymphosarcoma. During the follow-up observation period, she developed adenocarcinoma of the cervix. Intravaginal radium treatment was given. After completion of therapy, tenderness and swelling of the left leg appeared. Homans' sign and Lowenberg's cuff test were positive. Fibrinolysin therapy was started about 40 hours after the first sign of thrombophlebitis and was continued for three days. A moderately severe pyrogenic reaction followed the first infusion; there were no side-effects during the subsequent treatments. Homans' sign became equivocal, pressure sensitivity decreased, and there was marked reduction of edema on the day after the first fibrinolysin infusion. Rapid improvement continued, and resolution was essentially complete on the third day. The patient was then given heparin for several weeks. Six months after discontinuation of heparin and discharge, she was active without any complaints.

Case 8.—A 68-year-old woman underwent resection of a carcinoma of the bladder. Nine days later, she noted swelling and slight pain in the right foot. Four days after the onset of the process, she had 2+ edema of the right leg below the knee and dilated superficial veins of the leg. Homans' sign was negative; Lowenberg's cuff test was weakly positive. Venogram revealed obstruction of the posterior tibial vein. She received two infusions of fibrinolysin, on the fifth and sixth days after the swelling was discovered. She was also treated with heparin and bishydroxycoumarin. Repeat venogram on the seventh day showed no change. However, she improved rapidly, and the extremity was entirely normal three days later.

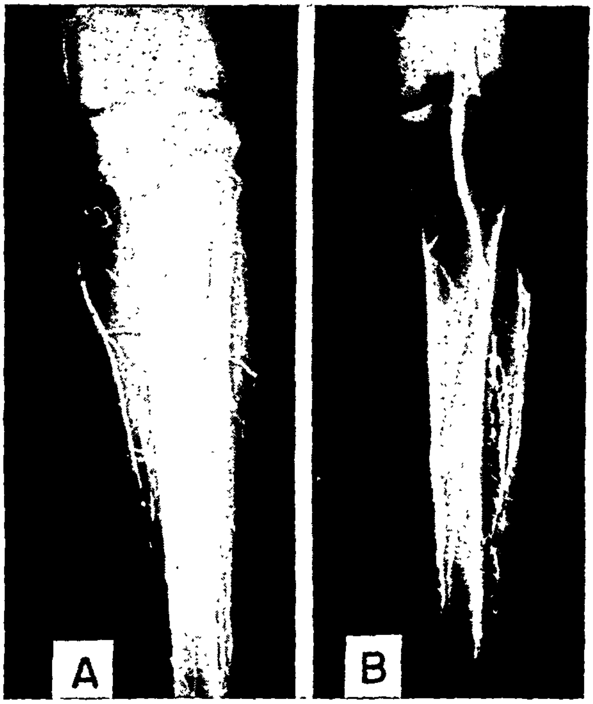

Fig. 2. (case 2).—Venograms of left leg taken, *A*, immediately before and, *B*, six days after beginning of fibrinolysin therapy. Previously occluded deep venous channels are now patent.

Case 9.—A 73-year-old woman with agnogenic myeloid metaplasia was admitted with swelling and pain of the left leg, of about five days' duration, and coldness and pain of the left foot, of one day's duration. The entire left extremity was swollen and tender. The foot was pale and cold; the leg exhibited bluish mottling; skin temperature was increased above the knee; and there was erythema and tenderness over the femoral vein. The left femoral pulse was diminished as compared to the right. The left popliteal and dorsalis pedis pulses were absent. The clinical impression was (1) left femoral thrombophlebitis and (2) arterial occlusion above the knee, due to either thrombosis or intense vasospasm. The patient was given heparin, and fibrinolysin therapy was instituted. She received four infusions of fibrinolysin during the 72 hours after admission, with mild to moderately severe reactions. Penicillin was also administered. On the morning after the first infusion, signs of arterial obstruction were no longer present but evidence of femoral thrombophlebitis and major venous obstruction persisted. Three days later, she was strikingly improved, but some edema of the leg was still present. More gradual improvement continued, bishydroxycoumarin was substituted for heparin therapy, and she was discharged one month later.

Case 10.—A 59-year-old woman had carcinoma of the ovary, with abdominal carcinomatosis, ascites, and moderate edema of both legs. Six hours after abdominal paracentesis, her right leg became painful, cyanotic, and more edematous. On succeeding days, the edema progressed to involve the entire extremity. Five days after the onset of thrombosis, the extremity was still painful, cyanotic, and markedly edematous. Homans' sign and Lowenberg's cuff test were strongly positive. She was given one infusion of fibrinolysin, with a moderately severe reaction. There was no improvement. Her general condition continued to deteriorate rapidly, and she died two days later. Autopsy revealed a thrombus completely occluding the right femoral vein.

* Metastatic renal carcinoma, severe peripheral vascular disease, and thrombosis of left popliteal artery.

† A = dorsum of foot, C = mid-calf, F = mid-thigh, G = patella.

Arterial Thrombosis and Embolism.—Arterial blood flow was restored eight hours after the administration of fibrinolysin in a case of probable popliteal artery thrombosis (case 9). A case of arterial embolism in a patient with advanced vascular disease was treated one day after the acute episode and embolectomy, without success. No favorable response was observed in another patient; the summary of this case follows.

Case 11.—A 53-year-old man with metastatic renal carcinoma, who also suffered from intermittent claudication of three years' duration, developed a series of superficial venous thromboses and an episode of pulmonary embolism and infarction. Anticoagulant therapy was administered. Hepatomegaly was present, with nodular hepatic masses. Needle biopsy of the liver was planned, and for this reason heparin therapy was discontinued. Two days later, pain, cyanosis, and ecchymoses developed in the left foot. Femoral pulse was present, but the popliteal, posterior tibial, and dorsalis pedis pulses could not be felt. Skin temperatures and oxygen tensions were lower than in symmetrical contralateral points. Breathing of pure oxygen resulted in increase of skin oxygen tension in the right leg and in the left thigh, but no changes occurred at points below the left knee. Table 3 presents some of the observations recorded in this patient and is illustrative of the procedures we are now using in suspected arterial occlusion. Fibrinolysin therapy was started about 24 hours after the first clinical signs were observed and was continued for two days. The patient was given heparin. A moderately severe pyrogenic reaction followed the second fibrinolysin infusion. No improvement was noticed, and eventually dry gangrene of the left foot and thrombophlebitis of the deep veins of the right leg developed, in spite of continued heparin therapy. The patient died two weeks later in hepatic coma. Autopsy revealed organized thrombi in the left popliteal artery and right popliteal vein.

Other Indications.—Several cases of edema, presumably secondary to venous or lymphatic obstruction, were treated. Two are of particular interest.

Case 12.—A 60-year-old man with carcinoma of the right tonsil, previously treated with radiation, developed acute swelling of the left side of the head and neck (fig. 3*A*). Palpebral edema prevented opening of the eyelids, and the patient complained of headache. The etiology of this episode was uncertain, but thrombosis of major veins draining this area was suspected. He was given two infusions of fibrinolysin on successive days, with mild side-effects. Penicillin therapy was also initiated, but cultures taken before treatment were later reported to be sterile. Five hours after the first infusion, there was a marked reduction in swelling of the face and the patient could open his eyelids. On the following morning, the head and neck appeared normal except for some redness of the face and slight edema of the mastoid area. During the next two days there was a complete return to normal status (fig. 3*B*).

Case 13.—A 43-year-old woman with recurrent postoperative bilateral adenocarcinoma of the breast was treated with androgens, oophorectomy, radiation, and hypophysectomy. She developed edema of the right shoulder and arm, presumably related to tumor extension. Later, marked edema of the hand appeared (fig. 4*A*). She was comatose, and no subjective information could be obtained. Fibrinolysin therapy was given about three days after the appearance of edema of the hand. Moderate chills and fever developed. Ten hours later, definite reduction of swelling was observed. There was slight oozing from the lesions of the chest wall, starting during the infusion and gradually subsiding. By the following morning, the edema of the right hand and forearm had completely disappeared (fig. 4*B*). No further treatment was given. During the next three days the edema gradually recurred.

Five patients with chronic edema of an extremity, of 3 to 12 months' duration, did not respond to fibrinolysin therapy. Three of these were women with postmastectomy edema of the arm. Two were women with intrapelvic cancer and edema of a lower extremity.

Three instances of skin flap cyanosis, in two patients, were treated. It was postulated that this disorder might be secondary to multiple thrombosis of small vessels in the flap. One patient, treated eight days after the onset of cyanosis, did not respond. The other, treated promptly on each of two occasions, showed rapid improvement both times.

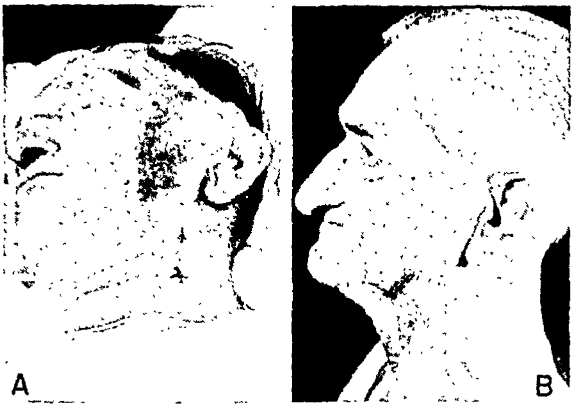

Fig. 3 (case 12).—*A*, before and, *B*, two days after beginning of fibrinolysin therapy. Edema has disappeared.

Case 14.—A 59-year-old man had a large basal cell carcinoma of the right side of the back. A pedicle flap was formed to repair the skin defect to be produced by surgical therapy. A month later a second delay dorsal flap was formed. Cyanosis of the flap developed, possibly due to small thrombi. Fibrinolysin therapy was instituted 24 hours after this occurrence and maintained for five days. Mild pyrogenic reactions were observed on the second and fifth days. There was definite improvement in the color of the flap after one day of treatment, and it was normal on the fifth day. Five days later slight cyanosis was again noticed. Fibrinolysin was administered for two days, without side-effects. By the third day the color of the flap was again normal. Three weeks later, the tumor was excised and skin grafting accomplished. The patient was discharged in good health two months later.

Comment

We have administered a relatively large number of different preparations of fibrinolysin to a relatively small number of patients, with the objective of identifying preparations suitable for clinical use in acutely and seriously ill patients. In most cases, several preparations were given to the same patient in order to compare side-effects more accurately. Several of the preparations we have tested appear satisfactory for general use. Detailed data on the methods of preparation, pharmacology, and clinical, biochemical, and hematological effects of these fibrinolysin preparations will be presented elsewhere.[10]

Our results suggest that fresh thromboses can be beneficially affected by fibrinolysin therapy. Of eight episodes of thrombophlebitis of three days' duration or less, complete resolution within one week was obtained in five and marked improvement in one. The natural history of this disease is quite variable, and our series of treated cases is small. It would be unwise to draw sweeping conclusions from this limited experience. However, the results in these patients parallel our observations in experimental animals and suggest that fibrinolysin may prove to be a useful therapeutic agent in this common and distressing disease. It is improbable that the majority of such seriously ill patients as ours would have had spontaneous resolution of their thrombotic processes in less than a week. In two cases of classic thrombophlebitis (cases 1 and 2) and one case of probable thrombosis complicating infiltrating carcinoma (case 13), the clinical syndrome recurred soon after termination of fibrinolysin therapy. The improvement associated with fibrinolysin therapy cannot, therefore, be ascribed to a coincidental remission of the tendency toward thrombosis in these patients. The venograms shown in figure 2 demonstrate that reopening of thrombosed channels actually occurred. To achieve this by the normal processes of organization and recanalization would require weeks or months.

The rapid subsidence of edema in the patients in cases 12 and 13 was quite striking. We believe that these cases represent silent venous thrombosis, with successful clot lysis by fibrinolysin. They were not included among the cases of thrombophlebitis, however, because of the lack of satisfactory criteria, other than edema, for making such a diagnosis. Similarly, in case 14, it appears reasonable to assume that the skin flap cyanosis was due to multiple small thromboses and that the improvement reflected lysis of these thrombi. However, proof of this hypothesis would have required biopsy of the flap, a procedure not considered desirable by the attending surgeon.

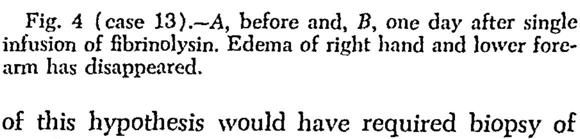

Fig. 4 (case 13).—*A*, before and, *B*, one day after single infusion of fibrinolysin. Edema of right hand and lower forearm has disappeared.

In our experience, fibrinolysin has proved useful only in acute thromboses. However, Cliffton[12] reported beneficial results in certain instances of thrombosis of relatively long standing.

Anticoagulants were deliberately withheld in many of our patients in order to make the test of fibrinolysin therapy as severe as possible. Since these patients had terminal cancer, we felt this was justifiable. However, fibrinolysin does not prevent the development of new thrombi, as demonstrated by the patient in case 3, who developed additional thromboses while undergoing fibrinolysin therapy. We believe, therefore, that the ideal management of acute thromboses should include anticoagulant therapy. In future cases, we plan to administer heparin immediately after the first fibrinolysin infusion and to maintain anticoagulant therapy for the usual period after clinical resolution.

Our experience in this series has impressed us with the difficulties of exact diagnosis of peripheral thrombosis and of evaluation of therapeutic responses. It is well known that thrombosis may be entirely silent. Many of the classic diagnostic criteria of venous thrombosis depend on the presence of an associated inflammatory response. If the inflammatory signs appear late, the age of the thrombotic process may be considerably underestimated. This may perhaps explain our therapeutic failure in a patient such as in case 4, who seemed to have an ideal case and who was treated "early" and aggressively with fibrinolysin and anticoagulants. On the other hand, subsidence of inflammation and restoration of normal circulation through an efficient collateral system can simulate complete reversal of the thrombotic process, when in fact there has been no dissolution of the clot. This was the situation in the patient in case 8, who would have been listed as having a "complete resolution," had not venograms been obtained before and after treatment. In patients with disseminated abdominal and pelvic tumors, such as in case 2, edema of a leg may persist even though the major venous channel has been reopened. Because of these difficulties, we have turned increasingly toward the use of serial venograms in our cases of thrombophlebitis. This technique improves the accuracy of diagnosis and makes the evaluation of therapeutic response much more precise.

Comparable difficulties were encountered in the evaluation of early arterial thrombosis. Coldness of an extremity may be due simply to cutaneous vasoconstriction. Palpation of arterial pulses at the knee and ankle is often difficult, even in patients who do not have arterial obstruction. These difficulties can be surmounted by the use of complex techniques, such as those employed in case 11. Failure of low tissue oxygen tensions to rise during inhalation of pure oxygen demonstrates unequivocally that arterial perfusion of the extremity has been interrupted. Even this technique, however, cannot differentiate between acute thrombosis, embolism, and intense arterial spasm causing almost total reduction of blood flow. In many cases, the exact diagnosis is made retrospectively. Thus, in case 11, a failure, the diagnosis of arterial thrombosis was proved by the development of gangrene and by the autopsy findings. However, in the patient in case 9, with a similar clinical picture and recovery, it cannot be stated with absolute certainty that arterial thrombosis was present. Somewhat similar findings have been reported in cases of acute massive thrombophlebitis.[13] However, the fact that signs of arterial obstruction followed the onset of thrombophlebitis by four days in our patient suggests that this was, in fact, a separate event.

We have not treated patients with coronary thrombosis in this study because we did not wish to submit such seriously ill patients to the possible hazards of side-reactions to fibrinolysin infusion and to the dangers of withholding anticoagulant therapy. However, the most important uses of fibrinolysin may well prove to be in treatment of acute coronary and cerebral thrombosis, where the natural consequences of the thrombotic process are so much more serious than in peripheral thrombophlebitis. A major purpose of the study reported here has been to develop preparations of fibrinolysin which can be administered safely to patients with acute coronary thrombosis. We now have several such preparations and hope to initiate a controlled clinical study of fibrinolysin therapy in coronary and cerebral thrombosis in the near future.

Sherry and Alkjaersig,[9a] Johnson and associates,[14] and Miller [15] demonstrated therapeutic effects in inflammatory and thrombotic conditions with intravenous, intramuscular, and buccal administration of streptokinase only. Presumably, these effects resulted from activation of patients' own profibrinolysin. If therapeutic levels of active fibrinolysin can be obtained consistently by such techniques, they may prove to be simpler methods of therapy than the administration of preformed fibrinolysin. The fact that streptokinase is a very potent antigen and may induce severe sensitivity reactions in man [10] may be a disadvantage of this approach, however.

Summary

Various preparations of the fibrinolytic enzyme, fibrinolysin (plasmin), have been administered to patients with thrombotic disorders. Rapid resolution of signs and symptoms has been observed in patients treated within a few days of the apparent clinical onset of thrombosis. Fibrinolysin therapy was ineffective when started one week or more after the first manifestations of thrombosis.

Many of the fibrinolysin preparations tested were deemed unsatisfactory because of low potency or a high incidence of side-reactions or because they were strongly antigenic and carried the hazard of inducing sensitization to streptococcic products. However, several preparations appear satisfactory for futher clinical trial in acute peripheral thromboses and in coronary and cerebral thrombosis.

Several patients treated only with fibrinolysin suffered recurrence of thrombosis soon after the completion of therapy. We believe, therefore, that fibrinolysin treatment should be supplemented by anticoagulant therapy to prevent such recurrent thromboses.

It must be emphasized that this approach to the therapy of acute thrombosis is still experimental. Much more work needs to be done before fibrinolysin can be recommended for general use.

666 Elm St. (3) (Dr. Sokal).

Chester Kucinski (University of Buffalo) and Arthur Eisen (University of Pennsylvania) participated in these studies as summer fellows. L. Alicandro, R.N., and A. Higgins, R.N. (research nurses), D. Reddington, B.S., I. Mink, B.S., and R. Shields, B.S. (technicians) provided technical assistance in these studies.

Several preparations of profibrinolysin and streptokinase-activated fibrinolysin used in this study were supplied by Drs. D. L. Kline and S. B. Fishman of Yale University, and K. H. Bayer, G. Bayne, and W. Baumgarten of Merck Sharp & Dohme, division of Merck & Co., Inc., Philadelphia. The chloroform-activated fibrinolysin used in this study was supplied by Drs. A. C. Bratton, M. F. Fahey, E. C. Loomis, and E. Weston of Parke, Davis & Company, Detroit. One of the urokinase preparations used in this study was supplied by J. Ploug of Leo Pharm. Co., Copenhagen, Denmark. Fraction 3 of human plasma used in this study was provided by Dr. J. N. Ashwort of the American Red Cross Blood Program, through E. R. Squibb and Sons, New York.

This study was supported, in part, by grants from the American Heart Association; the National Institutes of Health, U. S. Public Health Service; Merck Sharp & Dohme, division of Merck & Co., Inc.; and Parke, Davis & Company.

IRON-DEFICIENCY ANEMIA.—Several factors are thought to contribute to the iron-deficiency anemia of infancy. Included among these are decreased dietary iron, inadequate iron stores at birth, and excessively rapid growth. . . . Of the factors investigated the most frequently found was an abnormal diet. In those cases in which only one cause was found the large majority were due to abnormal diet. Low birth weight was much less frequently the single factor, and low maternal iron stores never acted alone, although in a larger series the latter factor might have been implicated as operating singly. Abnormal weight increment in full-term infants was also only rarely encountered as a cause of iron-deficiency anemia. It appears, therefore, that, given a normal diet, an infant overcomes his relative neonatal iron deficit. However, normal iron stores at birth are not adequate to prevent the development of iron-deficiency anemia in the presence of an abnormal diet.—J. P. Dawson, M.D., and J. F. Desforges, M.D., Dietary and Storage Factors in Iron-Deficiency Anemia of Infancy, *A. M. A. Journal of Diseases of Children*, August, 1958.

SPINAL ANESTHESIA FROM THE SURGEON'S STANDPOINT

Robert A. Scarborough, M.D., San Francisco

Spinal anesthesia has certain advantages over other types in operations below the level of the diaphragm. It gives a degree of muscular relaxation that cannot be attained in general anesthesia, even if relaxant drugs are used, without undesirable depression of respiratory and circulatory functions. In the author's experience with 5,000 operations with the use of spinal anesthesia there have been no deaths and no instances of permanent motor paralysis. It is assumed that both surgeon and anesthesiologist are on the alert for such possible complications as nervous apprehension, nausea, vomiting, respiratory depression, and cardiovascular disturbance. Postoperative urinary retention necessitated catheterization in approximately 30% of this series; it is doubtful whether this figure differs significantly from that for colonic and anorectal surgery under general anesthesia. The incidence and severity of headache have become negligible since techniques have been improved by using small-gauge lumbar puncture needles, avoiding multiple punctures of the dura, keeping the patient horizontal for at least 24 hours after operation, and making sure of adequate hydration. Two important contraindications are neurological disease and intestinal obstruction. Spinal anesthesia, properly used, has advantages that are especially appreciated by the surgeon operating for colonic and anorectal disease.

I am a representative surgeon who prefers spinal anesthesia for operations below the level of the diaphragm. More specifically, in my own particular field of surgery for colonic and anorectal disease, I believe that spinal anesthesia is the anesthesia of choice.

For anorectal surgery, complete muscular relaxation of the sphincter ani, levator ani, coccygeus, and gluteus muscles is essential for adequate exposure and satisfactory definitive procedure. It is desirable to have the patient in the prone position. When this position is used, it is important to avoid respiratory and circulatory depression. For fulfillment of these conditions low spinal saddle-block anesthesia is unquestionably the anesthesia of choice.

For abdominal surgery, two fundamental requirements are adequate muscular relaxation of the abdominal wall and a quiet, contracted intestine. Again, spinal anesthesia is unexcelled for producing these two conditions. To attain comparable results with general anesthesia requires a depth of anesthesia which produces both a central and a peripheral depression of respiratory ventilation and of circulation.

With the recent introduction of peripheral muscle relaxants, it is now possible to produce more adequate muscle relaxation with higher levels of anesthesia. Today, a well-administered general anesthesia, combined with judicious use of muscle relaxant drugs, more nearly approaches, but does not fully achieve, the distinctive advantages of spinal anesthesia.

As Dripps and Vandam[1] said, "Spinal anesthesia . . . is relatively free from the criticism of toxicity and the mortality associated with general anesthesia . . . the great hazard of spinal anesthesia in the minds of both physician and patient is the possibility of persistent paralysis after the anesthetic effects should have disappeared." In all truth, such hazard does exist, as demonstrated by a number of reported cases in the medical literature.

In 1950, Kennedy and co-workers[2] published a vindictive attack on spinal anesthesia, with a report of 11 tragic examples of severe neurological complications following spinal anesthesia. It was their opinion that paralysis below the waist is too large a price for the patient to pay in order that the surgeon should have a fine relaxed field of operation. There can be no argument with this opinion, provided that the incidence and severity of such complications are sufficient to outweigh the advantages of this form of anesthesia. There is abundant evidence that this is not the case.

Review of the Literature

In the table is listed the reported experience of seven outstanding authorities, supplemented by an additional 5,000 consecutive private patients operated on by myself with use of spinal anesthesia. These are series of consecutive cases numbering from 2,300 to 12,000 in which specific study of the incidence of neurological complications was carried out. Particularly noteworthy is the excellent report by Dripps and Vandam[1] from the University of

Read in the Symposium and Panel Discussion on Spinal Anesthesia before the Joint Meeting of the Section on Anesthesiology and the Section on Surgery, General and Abdominal, at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

Pennsylvania Hospital. This was a comprehensive prearranged plan of study with long-term follow-up of all patients who received spinal anesthesia over a period of four years. In the opinion of these authors this intensified search for suspicious symptoms in all probability increased the number of symptoms and invited extraneous complaints. As an example, they give this reply received from one patient: "After getting your letter I seem to think I am having after-effects."

In these 65,677 cases, there was not a single instance of permanent motor paralysis. Also recorded in the table are four deaths. The two reported by Jackson and Petsch [3] occurred in 1930, in their early experience with spinal anesthesia. The two reported by Sadove and Levin [4] occurred in patients who were moribund before induction of anesthesia and who died of cardiac arrest. Sadove and Levin believe that possibly these patients should have had only refrigeration anesthesia.

Neurological complications reported by these workers were as follows: Transient paresthesias of the lower extremities, most commonly in the skin area supplied by the lateral femoral cutaneous nerves to the thighs, occurred in 93 patients, or 1 in 700 (0.14%). Transient motor weakness in the lower extremities was reported in seven cases, or 1 in 9,000 (0.01%). Transient abducens nerve palsy occurred in eight patients, or 1 in 8,000 (0.012%). Transient backache and muscle spasm occurred in four patients (0.006%). While these are included as possible neurological complications, probably they were skeletal in origin. Mild transient meningismus also was reported in four cases. There was one reported case of aseptic benign meningitis, with complete recovery.

In one patient neurological signs developed, subsequent to spinal anesthesia, which proved to be due to a meningioma of the spinal cord. Cure was effected by definitive surgery for the meningioma. In one case of persistent paralysis of the left peroneal nerve, preexisting symptoms of such paralysis had been present and this was not considered to be a neurological complication of spinal anesthesia. The majority of these reports contained no data on headache after spinal anesthesia. This will be discussed with other postoperative complications.

Complications During Spinal Anesthesia

Both the anesthesiologist and the surgeon must be cognizant of possible untoward reactions during and after spinal anesthesia, so that they may intelligently employ proper procedures of prevention and treatment for such reactions. Complications during anesthesia can include nervous apprehension, nausea and vomiting, respiratory depression, circulatory depression, and cardiac arrest.

Nervous Apprehension.—The patient's apprehension can be minimized by adequate discussion of the procedure with him in advance by both the surgeon and the anesthesiologist. Appropriate sedation should be used, along with "supplemental vocal anesthesia" by the anesthesiologist during the operation. The latter in no way alludes to the utilization of hypnosis.

Nausea and Vomiting.—When nausea and vomiting occur, they are usually proportional to the degree of nervous apprehension on the part of the patient. This may be controlled promptly by minimal amounts of intravenously given meperidine (Demerol) hydrochloride or thiopental (Pentothal) sodium.

Respiratory Depression.—The degree of respiratory depression present is directly related to the level of anesthesia; this is true particularly in paralysis of the intercostal muscles. It may also be caused by injudicious preoperative sedation. When such depression occurs, artificial respiratory exchange and oxygen must be utilized to prevent anoxia and circulatory collapse.

* No instance of permanent motor paralysis was reported by these workers.

Circulatory Depression.—In my experience with saddle-block spinal anesthesia for anorectal surgery, rarely does any significant amount of hypotension occur. The average drop in systolic pressure is less than 10 mm. Hg.

In abdominal operations, with the necessity of a higher level of anesthesia, there may occur a serious drop in blood pressure unless the anesthesiologist takes appropriate control measures. In my experience in working with highly qualified anesthesiologists, blood pressure seldom drops more than 20 mm. Hg and, when it does, rarely stays below that level for as long as five minutes. In every abdominal operation continuous intravenous infusion is maintained for fluid and blood replacement and for any indicated intravenous medication.

Cardiac Arrest.—In the collected series of 65,677 spinal anesthesias there were three reported cases of cardiac arrest, with one recovery. Two of these three patients were moribund before induction of anesthesia. In my experience, cardiac arrest has not yet occurred.

Complications After Spinal Anesthesia

It is axiomatic that the responsibility of the anesthesiologist and the surgeon for the welfare of the patient does not end when the patient is wheeled from the operating room. Appropriate measures need to be taken for the prevention or treatment of four principal postanesthesia complications: hypotension, nausea and vomiting, urinary retention, and headache.

Hypotension.—Any fall in blood pressure produced by spinal anesthesia may recur as long as the anesthesia is effective, unless appropriate control measures are maintained until the effects of the anesthesia have terminated. It is also noteworthy that any sudden movement of the patient during transfer from operating table to bed or Guerney may initiate a significant drop in blood pressure.

Nausea and Vomiting.—In my experience the incidence of nausea and vomiting as a postoperative complication is no greater with spinal anesthesia than with general anesthesia for comparable surgical procedures.

Urinary Retention.—It is generally believed that the incidence of urinary retention in the immediate postoperative period is greater after spinal anesthesia than after general anesthesia. I have never been convinced that this is so, although I can offer no statistical data to refute this belief. Catheterization has been done in approximately 30% of my patients who have had anorectal surgery under spinal anesthesia. This incidence of the use of catheterization in good part reflects an unwillingness to permit overdistention of the bladder in the immediate postoperative period. In my experience there has been no instance of persistent neurogenic dysfunction of the bladder after spinal anesthesia.

Headache.—The incidence of headache after spinal anesthesia is variously reported in the literature as from 1.5 to more than 30%. It is generally agreed that such headache is directly related to the leakage of cerebrospinal fluid at the site of needle puncture of the dura. By employment of a few simple preventive measures, I have found that the incidence and the severity of headache after spinal anesthesia have become negligible. These procedures include the use of a small-gauge lumbar puncture needle, avoidance of multiple punctures of the dura, horizontal position of the patient for at least 24 hours after operation, and adequate hydration.

With the use of these simple preventive measures, only occasionally has it been found necessary to prescribe any specific treatment for headache after spinal anesthesia. In an occasional instance persistent headache, not promptly relieved by placement in the horizontal position, has occurred in tense individuals who have had prolonged nausea and retching after operation. Adequate hydration by intravenous infusion plus medication with tranquilizers to ameliorate nausea and tension has given prompt relief.

Contraindications

It is advisable to avoid the use of spinal anesthesia in patients with any history or signs of neurological disorder or injury or disease of the spinal column. In many instances this is a precautionary measure, to avoid any possible or presumed aggravation of such disorder.

I do not employ spinal anesthesia for abdominal operations in the presence of intestinal obstruction, because of the danger of precipitating intestinal perforation and because of the possibility of regurgitation and aspiration.

When abdominal surgery is considered imperative in a patient who is comatose or in severe shock, I believe that both spinal and general anesthesia are contraindicated and prefer local procaine infiltration or block anesthesia.

I do not consider preexisting cardiovascular disease a contraindication to the use of spinal anesthesia. My experience supports the published conclusion of Lorhan and Merriam[5] that spinal anesthesia is excellent for elderly and poor-risk patients, including those with advanced cardiac and hypertensive disease.

Conclusions

In every patient the selection of the type of anesthesia to be employed should be determined, first, on the basis of safety for the patient and, second, on the basis of relative advantage to the surgeon. In my experience, such selection has resulted in the use of spinal anesthesia for the great majority of operations for colonic and anorectal disease.

PHARMACOLOGY OF COMPOUNDS USED TO PRODUCE SPINAL ANESTHESIA

Robert M. Featherstone, Ph.D., San Francisco

The several compounds used to produce the extensive nerve block called spinal anesthesia are all members of a group classed as "local anesthetics." They have many characteristics in common, and they are thought to produce their effects in a common manner. The quantitative differences among them result primarily from the influence of the differing chemical structures on such factors as absorption, penetration of membranes, metabolic reactions, and excretion mechanisms. These individual factors achieve more or less importance as we consider the compounds in the special case of spinal anesthesia. This technique was first used in 1899, but cocaine was the drug employed and a number of deaths resulted.

Characteristics of Local Anesthetics

The figure shows the names and structures of five representative compounds which have been more recently used in this field. These are procaine hydrochloride, tetracaine hydrochloride, piperocaine hydrochloride, dibucaine hydrochloride, and lidocaine hydrochloride. The first three of these compounds are tertiary amino esters of aromatic acids, and the last two are amides rather than esters, with the carbamino group turned around in the lidocaine molecule—a rearrangement which in this case can be utilized to achieve excellent local anesthetic activity without the liability of sensitivity reactions from the ester type of compounds.

The characteristic action shared by these compounds is their ability to block nerve conduction when they are applied locally to nerve tissue in sufficient concentration. They act on any part of the nervous system and on every type of nerve fiber from the motor cortex to the peripheral afferent nerve endings. In the spinal cord, a functional transection is provided. The reversible nature of this action and the complete recovery of nerve function allow the production of discrete local paralysis of sensory and motor nerves.

The features desirable in a good local anesthetic for spinal use are summarized as follows: (1) depression of sensory nerve function; (2) reversible action, with no damage to nerve tissue; (3) selective action on nerve tissue; (4) low systemic toxicity in concentrations used clinically; (5) no irritation or pain at injection site; (6) rapid onset of action; (7) optimum duration of action; (8) solubility in aqueous solutions at usual pH; (9) stability during sterilization and in solution; and (10) compatibility with vasoconstrictors. The five compounds being considered are nonirritating and do not injure nerves as they produce anesthesia. In producing spinal anesthesia, such small amounts are used, compared to the amounts used for infiltration, that systemic toxicities are probably not generally a major factor. However, one would choose a compound with the greatest margin of safety if the desirable activity is still equally present, since it is difficult to confine the drug to one spot and the spread may well incapacitate vital processes. The local anesthetics differ from some other groups of compounds, such as barbiturates, in that the anesthetic potencies and toxicities are not strictly proportional. This is perhaps due to the relatively greater nonspecificity of the local anesthetics' action in producing anesthesia and the dependence of their toxicity potentials on specific structural features. Time and lack of detailed knowledge does not permit a much greater exploration of this point.

The features desirable in a good local anesthetic for spinal use are summarized as follows: (1) depression of sensory nerve function; (2) reversible action, with no damage to nerve tissue; (3) selective action on nerve tissue; (4) low systemic toxicity in concentrations used clinically; (5) no irritation or pain at injection site; (6) rapid onset of action; (7) optimum duration of action; (8) solubility in aqueous solutions at usual pH; (9) stability during sterilization and in solution; and (10) compatibility with vasoconstrictors. The duration of the anesthetic action is a matter of greatest importance in spinal anesthesia. Means of increasing the duration are (1) use of another drug, (2) use of continuous spinal anesthesia, or (3) use of vasoconstrictors. The maximal reflex vasoconstriction in unanesthetized areas occurring as a normal part of spinal anesthesia renders patients especially susceptible to shock and hemorrhage.

The duration of the anesthetic action is a matter of greatest importance in spinal anesthesia. The duration is often shorter than is desired. One can increase the time of effect by increasing the dose, but to do this is to invite greater spreading, greater

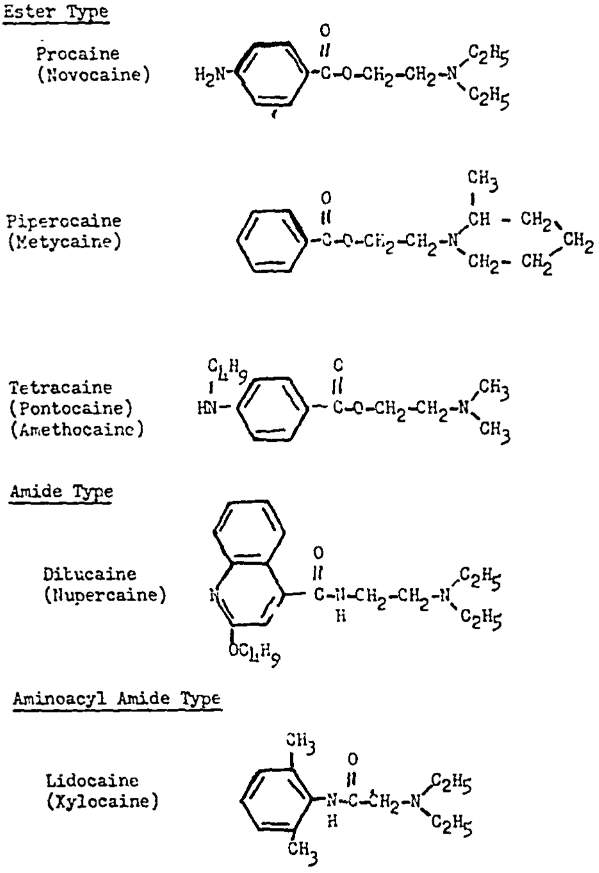
Read in the Symposium and Panel Discussion on Spinal Anesthesia before the Joint Meeting of the Section on Anesthesiology and the Section on Surgery, General and Abdominal, at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

absorption, and greater potential toxicity, with an attending greater decrease in blood pressure. Other means of increasing the duration are (1) use of another drug, (2) use of continuous spinal anesthesia, or (3) use of vasoconstrictors. With the continuous technique, the uncertainty of duration can be overcome, the control can be better for high sensory blocks, and a shorter acting drug can be used. Vasoconstrictors work because the anesthetics are not destroyed in the subarachnoid space. Even procaine is not hydrolized. The anesthetic compounds are slowly absorbed systemically and are inactivated. It is thought that they leave the subarachnoid space mostly by venous drainage. Thus, the vasoconstrictors allow up to 100% greater duration of procaine action due to decreased rate of absorption. Epinephrine hydrochloride (0.2 to 0.5 mg.), levarterenol bitartrate (0.5 mg.), and phenylephrine hydrochloride (3 to 10 mg.) have been used. No systemic and no adverse effects on neural tissues are known to occur. The time required for onset of anesthesia would seem to be a relatively minor point for comparison in spinal anesthesia.



Structures of five representative compounds used in spinal anesthesia.

The physical properties of these compounds meet the ideal requirements fairly well, otherwise they would not have been used in this field. They are more soluble in aqueous solvents in acid solutions (lower than pH 7.0) and more soluble in lipids at a slightly alkaline pH; both of these properties are desirable in getting the molecules past an aqueous phase and into a lipid one where they apparently do their work, even though in an extremely local sense they may ionize again within the membrane. If, for some reason, the tissue pH is acid, the free base will not form and the attempt at anesthesia will fail. These relationships are illustrated in the following two equations: (1) $R{:}N \cdot HCl + NaHCO_3 \longrightarrow R{:}N + NaCl + H_2CO_3$; (2) $R{:}N + HOH \rightleftarrows R{:}NH^+ + OH^-$. The most stable compound of the five we are considering seems to be lidocaine, followed by tetracaine, and the other three in a third group. They can all be boiled and autoclaved at 120 C.

It has been noted that the systemic toxicity from these compounds used in spinal anesthesia is generally slight. Nevertheless, there are occasional reports of acute toxic reactions resulting in death from seemingly small amounts of procaine (100 mg.) and tetracaine (10 mg.). Such sensitivity reactions may be eczematous (asthma) or fatal anaphylactic responses; they seem to occur primarily with the procaine or ester type of compound. For want of greater knowledge about mechanisms, not much more can be said about these cases other than the fairly meaningless statements that either they represent an early sigma in the dose-response curve or some special feature of the patient's pathological state has led to the greater sensitivity.

Mechanisms of Action

Pertinent data on these compounds are presented in the table. However, a few other factors deserve brief mention. The volume of solution has a great influence on the level of anesthesia. The area is greater with greater volume. Generally, 1 to 10 ml. is used, depending on the level desired and the extent of control sought through volume. The total amount must be enough to produce nerve block and the desired duration. More drug covers more area and provides longer anesthesia. Operations on the lower part of the abdomen require only a small amount, because little upward diffusion is neces-

Data on Action of Five Local Anesthetics

	Usual Concentrations, %	Volume of Solution, Ml.	Range or Maximum Dose, Mg.	Relative Promptness	Duration, Hr.
Procaine	3.0-5.0	2-5	50-200	2	1-1½
Tetracaine	0.3-0.5	3-5	10-15	2	3-5
Piperocaine	3.0-4.0	3-5	50-200	2	2+
Dibucaine	0.05-0.25	...	3-13	3	4-6*
Lidocaine	2.0-4.0	4	150	1	2½-3

* Suggested by Dr S. C. Cullen as typical.

sary. As the desired area increases, the total dose must be raised. The degree of increase of dose depends on use of this factor as a control. A slow speed of injection usually allows for a slow diffusion, but increased speed gives greater spread. Barbotage may be used if it is desired to achieve thorough mixing. By changing the composition with such a substance as glucose, the specific gravity can be varied. "Hyperbaric" solutions are those with greater specific gravity than spinal fluid. "Hypobaric" solutions are made by putting drugs in hypotonic solutions. Many anesthetists control the direction of flow both by position of the patient and by the specific gravity.

Let us consider next the mechanism by which these compounds produce anesthesia. I have already stated that these compounds are most stable in their salt forms, that is, in slightly acid solution. However, in the slightly alkaline body fluids, the free base is liberated. This form of the compound is more freely soluble in the lipoid nerve structures and apparently is easily transported to the site where it does its work of depressing sensory nerve perception.

In a physiological sense we can stop there with this explanation of the mechanism, but we would be much more sophisticated if we could say more about this action, as it involves the so-called levels of integration lower than the tissue—the nerve in this case. In other words, what are these compounds doing at the cellular level or at the various subcellular levels—the polymolecular systems, the molecular systems, the molecules, and other systems?

Several so-called theories of action have been proposed, and most of them seem rather incomplete when they are examined critically. The degree of surface tension alteration at oil-water interfaces has been shown to parallel potency. This surface tension change produces decreased permeability of cell membranes, so that there would be a decrease in phasic shifts associated with nerve conduction. Acetylcholine production may be depressed. We have in some way a "stabilization" of the membranes so that the necessary depolarization cannot occur. Pores are closed by the physical presence of these local anesthetic drug molecules. These and other statements have been made to explain the phenomenon. When we look carefully among these phrases, each of which has satisfied some group of experimenters, depending on the limits of their interests, we can still ask the simple questions: "How do the local anesthetics work?" "What are the details of the transmission of the nerve impulse?" Actually, the local anesthetics serve as excellent tools in this important field of research. These compounds do block without depolarizing nerves, therefore are said to "stabilize" conditions in membranes which are normally labile enough to permit phasic shift in potential during impulse conduction. Generally, sensory fibers are blocked first and a separation can be made. There is an order generally to the disappearance of perceptions—pain first, then cold, warmth, touch, and deep pressure, but there is great individual variation. Fiber size seems to be a major determining factor here. Return of blocks to normal occurs in reverse order.

Comment

The chief pharmacological and toxicological effects of local anesthetics are summarized as follows: There is nerve conduction block, and respiration may be depressed. Local anesthetics are central nervous system stimulants; restlessness, tremor, and chronic convulsions may occur. Depression follows with respiratory failure, so that artificial respiration and drug stimulants may be needed. Barbiturates prophylactically are useful. A curare-like action is produced at the myoneural junction. Local anesthetics seem to diminish acetylcholine production.

Cardiovascular actions are as follows: With high systemic concentrations, quinidine-like changes occur in excitability, conduction, and force of contraction. There is arteriolar dilatation. Cardiac arrest may take place either by action on the pacemaker or by sudden onset of ventricular fibrillation, and cardiovascular collapse follows. In regard to circulation, blood pressure may drop in an unpredictable fashion but roughly is proportional to the area of anesthesia. The mechanism of action is disputed: There is paralysis of sympathetic fibers in anterior nerve roots and block of impulses to arterioles and veins; this arteriolar effect leads to a decrease in peripheral resistance and in systolic and diastolic pressures; and the venous effect leads to a postarteriolar pooling of blood, decrease in venous return, and reduced cardiac output. Extreme muscular relaxation of spinal anesthesia contributes to the decreased venous return. Anoxia would further contribute to circulatory inadequacy; final circulatory status depends on balance between these factors.

The maximal reflex vasoconstriction in unanesthetized areas occurring as a normal part of spinal anesthesia renders patients especially susceptible to shock and hemorrhage. Thus, tissues should be handled gently and patients in shock should not have spinal anesthesia.

Fall in blood pressure would be more serious if other drugs did not help. Ephedrine hydrochloride, 50 to 100 mg. intramuscularly, given prior to the spinal anesthetic, may be useful. Other compounds used include phenylephrine, hydroxyamphetamine hydrobromide, and methoxamine hydrochloride.

There is a spasmolytic action on smooth muscles. Also, neurological complications may occur. Apparently, it is difficult to distinguish the role of faulty technique. The incidence rate is about 1 to 1,000. The most common problem is the cauda equina syndrome. The symptoms are loss of control of sphincters of bladder and intestine and sensory and motor difficulties in the lower extremities. There is slow or no recovery. Less frequent complications are neuritis (radiculitis), myelitis, meningomyelitis, and myeloradiculitis. Many times these are only aggravated and not initiated. Other complications, such as focal cerebral lesions and cerebral nerve palsies, may be secondary to anoxia.

The evaluation of the technique of spinal anesthesia and the relative merits of single dose and continuous procedures are definitely in the sphere of the anesthetists and the surgeons who follow this program.

SPINAL ANESTHESIA, ARACHNOIDITIS, AND PARAPLEGIA

Samuel I. Joseph, M.D., Ph.D.
and
Judson S. Denson, M.D., Los Angeles

The effects of various detergents left as contaminants in the needles and syringes used for spinal anesthesia were studied in experiments with 18 monkeys. There were three test groups: a series of five monkeys in which a variety of detergents were used as contaminants, a series of five monkeys in which the contaminant was a 1 % solution of tribasic sodium phosphate (TSP), and a series of four monkeys in which the contaminant was 5% TSP. There was a contrast group consisting of four monkeys who were observed for five months or more after spinal anesthesia had been induced with due precautions against contamination with detergents. In this group no clinical, gross, or microscopic evidence of neurological damage was obtained. In the test groups only two monkeys escaped arachnoiditis; all the others developed it in varying degrees of severity, and one became clinically paraplegic. Detergents are not the only contaminants to be concerned about, but it is clear that extreme care should be used in all phases of the induction of spinal anesthesia.

Arachnoiditis and paraplegia after spinal anesthesia have recently been ascribed to detergent cleanser residues in the inadequately rinsed needles and syringes used for administration of spinal anesthesia.[1] It has been confirmed that this view has been based on strong circumstantial evidence without experimental verification.[2] Preliminary experimental work in monkeys, in support of the circumstantial evidence, was reported in brief from this department in 1957.[3] The present report is concerned with the continuation and expansion of the preliminary study.

Methods

The animals used were young adult male monkeys (the macaque) weighing between 3 and 10 lb. (1.3 and 4.5 kg.). The animals were put to sleep with pentobarbital (Nembutal), injected intraperitoneally; they then were subjected to spinal anesthesia with use of 1% tetracaine hydrochloride and 10% dextrose solution in varying hyperbaric combinations ranging from 2 to 4 mg. of tetracaine and 20 to 80 mg. of dextrose. The dose of tetracaine used was 2 mg. in all monkeys except two of the larger animals. Low lumbar puncture was performed with a 22-gauge needle. Spinal anesthesia was produced to various thoracic sensory levels.

The technique used for administration of spinal anesthetic drugs in the monkeys was as exactly comparable to that used in human patients as possible. In regard to the equipment used, in the control group of animals the syringes and needles used had been prepared for patients and in the experimental animals the syringes and needles had been washed in detergent solutions and then autoclaved without rinsing.

Read in the Symposium and Panel Discussion on Spinal Anesthesia before the Joint Meeting of the Section on Anesthesiology and the Section on Surgery, General and Abdominal, at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

In the exploratory preliminary experimental group, as previously reported,[3] various detergents commonly used in hospitals for the cleansing of needles and syringes were used in varied combinations and concentrations. Two of the five monkeys in this group received single contaminated injections, one received two, one received three, and one received four.

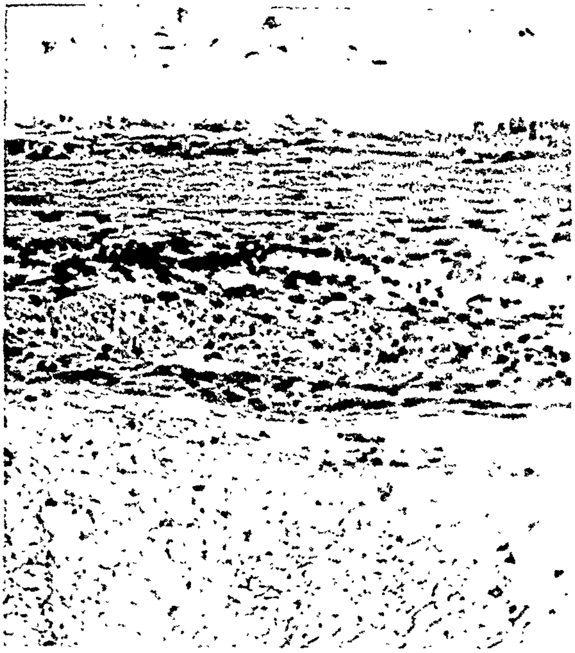

Fig. 1.—Marked inflammatory reaction in severe arachnoiditis in monkey. Note adhesion between pia and arachnoid (× 250).

In the present experimental group, tribasic sodium phosphate (TSP), commonly found in commercial detergent mixtures and also used by itself for similar purposes, was the only contaminant introduced (in 1 and 5% concentrations). Each animal in this group received just one injection.

At the conclusion of the observation periods, the animals were again put to sleep with pentobarbital injected intraperitoneally and the spinal cords, with intact meninges, were removed for study.

Results

Control Series.—Four animals were observed for five months and three for nine months after the induction of spinal anesthesia. No clinical evidence of neurological damage was noted, nor was gross evidence of neuropathology seen at sacrifice. Microscopic studies revealed no chronic meningeal reaction.

Preliminary Experimental Group.—Five animals in the preliminary experimental series were observed for 6 to 14 months after the initial injection. One monkey (no. 4) was observed to be clinically paraplegic four months after its first anesthesia, or two months after its second anesthesia. The onset of paraplegia was clinically abrupt, without detectable premonitory symptoms. Six months after the onset of this animal's gross hind-limb paralysis, the beginning of clinical improvement was apparent. This improvement continued over a three-month period, with slight weakness of the lower extremities remaining as the only evident residual at the time of sacrifice. The other four monkeys remained clinically normal.

Study of the spinal cords and their investments revealed arachnoiditis in all. The pathological changes were graded as "severe" in one monkey, "moderate" in two, and "mild" in the remaining two. The pathology, summarized, was as follows:

Severe Changes: Marked inflammatory reaction of subarachnoid space, with practically solid adhesion between pia and arachnoid, was observed in one monkey (no. 4), as illustrated in figure 1. There was marked thickening of the walls of blood vessels, producing severe degenerative changes in nerve fibers associated with thickening about the trunks and binding of the nerve roots together (fig. 2), and lymphocytic infiltration of blood vessel walls. Proliferative changes in dorsal root ganglions, with chromatolytic changes in ganglion cells were also seen. There was loss of myelin in the peripheral

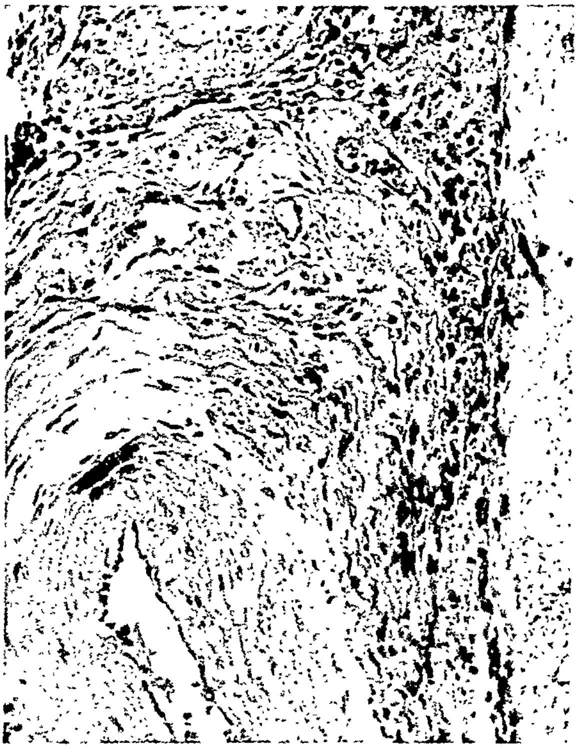

Fig. 2.—Severe degenerative changes in nerve fibers, with thickening about trunks and binding of roots, in monkey with experimentally produced arachnoiditis (× 250).

tissues of cord, especially of the posterior and lateral funiculi (fig. 3). Pathology was graded as 4+. The animal had received two injections.

Moderate Changes: One monkey (no. 5) had irregular thickening of the arachnoid and pia-arachnoid adhesions. Pathology was graded as 2+. The animal had received one injection.

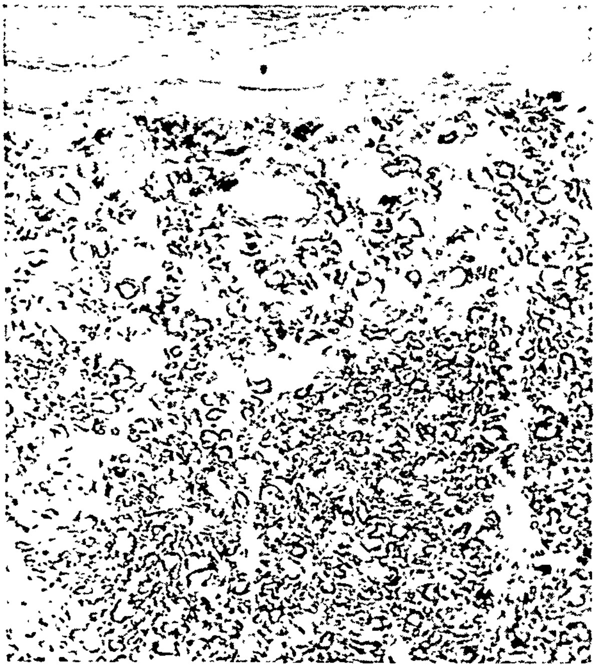

Fig. 3.—Loss of myelin in peripheral tissues of cord (× 250).

. In another animal (no. 2) with irregular thickening of arachnoid, the adhesions were all of meninges. The pathology was graded as 2+. This animal had received four injections.

Mild Changes: One animal (no. 8) showed a slight thickening of pia-arachnoid, with adhesions of nerve roots. The pathology was graded as 1+. The animal had received one injection. Another monkey (no. 1) had irregular thickening of arachnoid and nerve root demyelinization. Pathology was graded as 1+. The animal had received three injections.

No correlation could be made in this group of the extent or degree of pathology, the number of injections which each animal received, and the particular detergent used.

Present Experimental Group.—In four animals in the present experimental series spinal anesthesia was induced with use of needles and syringes contaminated with a 5% TSP solution. In two of these, sacrificed three and seven months after injection, respectively, the appearance of the spinal cords and meninges did not differ from that in the control animals. In a third animal, sacrificed three months after injection, slight hind-leg weakness was noted at the time of sacrifice. Gross observation of the meninges revealed a small (2-by-3-mm.) cyst of the dura at the site of lumbar puncture. Microscopic examination of the cord and meninges revealed minimal pia-arachnoid thickening, with some adhesion formation. In the fourth animal in this group, sacrificed three months after injection, no clinical evidence of neuropathology was noted. Examination of the cord and meninges revealed moderately severe arachnoiditis (3+), with adhesions between nerve roots, vacuolization of nerve roots (fig. 4), and marked cellular reaction in the meninges.

Five animals in the present experimental group were given an injection with needles and syringes contaminated with a 1% TSP solution. Two of these were sacrificed three months after injection, one five months after injection, and two eight months after injection. The appearance of the spinal cords and meninges of these animals did not differ from that of the control animals.

Comment

We know that serious neurological complications of spinal anesthesia were observed prior to the development and use of detergent cleansing solutions.[4] We also know that valid comparison of the incidence of such complications in the past decade with the incidence in more distant past cannot be made, particularly since incidence per se, unrelated to anesthesia, is so indefinite. However, it is difficult for us to believe that improved publicity is the only real basis for the apparent increased incidence of complications as reported in the literature, especially since this apparent increase so closely parallels the widespread use of detergents.

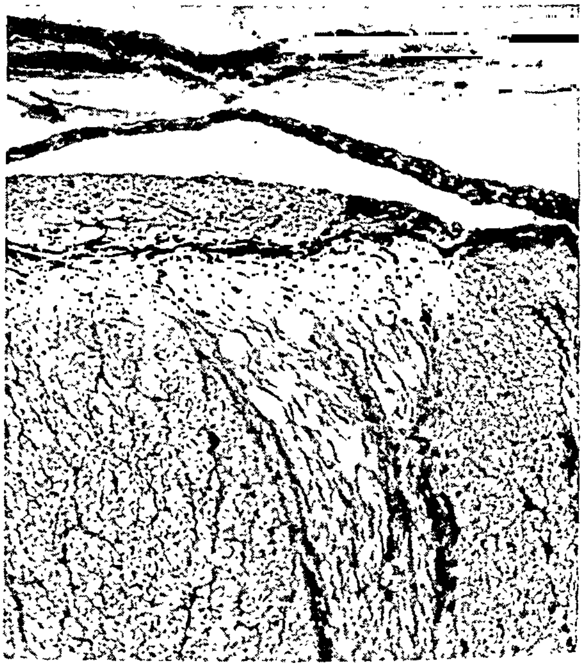

Fig. 4.—Vacuolization of nerve roots in monkey with moderately severe arachnoiditis (× 125).

The great number of uncomplicated spinal anesthesias which have been recorded through the years must be regarded as attesting to the relative safety of the anesthetic drugs themselves as they are generally used in modern practice. Therefore, clinical reports of neurological complications implicating contaminants cannot be ignored.

This study should not be construed as *suggesting* that detergent contaminants are the only contaminants with which one need be concerned in the administration of spinal anesthesia. Many histotoxic chemicals, including antiseptics, can undoubtedly produce comparable pathology.[5] Since detergents resist rinsing, extra diligence must be applied to their removal from syringes and needles. Since alcohol is often the solvent for antiseptic solutions used for skin preparation, care must be taken to avoid contamination of gloves, needles, syringes, and ampuls by such solutions. The dangers of "wet" (i.e., immersion) sterilization with alcohol or other antiseptic solutions of ampuls of drugs used for spinal anesthesia have been well documented.

Although chemical contamination no doubt does not represent the final explanation of the problem, it is a controllable aspect of it. Still remaining to be explained are the facts that arachnoiditis and paraplegia have been found in patients who have never received any type of anesthetic drug, as well as in patients who have been under only general anesthesia.

Summary and Conclusions

Spinal anesthesia was induced in a series of nine monkeys with needles and syringes which had been washed in strong detergent solutions and then autoclaved without rinsing. Seven of the animals were shown to have arachnoiditis when they were sacrificed 3 to 14 months after injection. In two of these the arachnoiditis was severe, with one animal clinically paraplegic.

Inadequate rinsing of hurriedly prepared detergent solutions, which can so readily be made far stronger than necessary, has been postulated as a hospital situation which can result in detergent contamination of solutions used for spinal anesthesia. Beginning with the care and cleansing of needles and syringes, extreme care must be observed in all phases of the induction of spinal anesthesia in order to avoid introducing potentially histotoxic substances into patients.

EFFECT OF ALTITUDE ON ASTHMA.—Patients with asthma may fly, preferably in pressurized planes, using the criteria with which the examining physician is best acquainted. Chronic bronchitis, asthmatic bronchitis, and bronchiectasis, unless severe, do not bar flying but moderate pulmonary emphysema might do so, particularly in the presence of large blebs. Patients who have dyspnea at rest on the ground will probably not find their symptoms aggravated at altitudes in pressured aircraft. Asthmatic patients sensitive to pollens may find some relief even though flying during their particular pollen season, but should not fly during an acute asthmatic attack. Vital capacity, in itself, should probably be above 50 per cent of the calculated value. While oxygen and various types of bronchodilators could be made available to passengers, the particular medication, as prescribed by a physician and with which the patient is familiar, is to be preferred. Prophylactic treatment prior to flight may help prevent attacks. Hyperventilation particularly during an initial trip by air, must be distinguished from asthma and this is at times quite difficult to do. Cyanosis, if present, without further consideration is sufficient in itself to keep a patient out of the air.—S. W. Simon, M.D., The Effect of Altitude on Asthma, *The Journal of Aviation Medicine,* June, 1958.

IS HEAT STERILIZATION OF LOCAL ANESTHETIC DRUGS A NECESSITY?

L. Donald Bridenbaugh, M.D.
and
Daniel C. Moore, M.D., Seattle

Heat sterilization of all local anesthetic drugs and equipment is mandatory but is not being generally practiced. A survey of the techniques observed in using local anesthetic drugs showed that only 33 out of 101 hospitals were autoclaving the solutions before use. The remaining 68 hospitals depended on cold sterilization, the immersion of the ampul, vial, or bottle in a germicidal solution which acts upon the outside but not on the contents. Experience with 17,368 regional block procedures over a 54-month period has led the authors to conclude that a careful technique which includes the autoclaving of the anesthetic in its container is mandatory. The procedure here described is based on the demonstration that the local anesthetics most commonly used can be autoclaved for 30 minutes at 255 to 260 F. and 18 to 20 lb. of pressure (124 to 127 C and 1.22 to 1.36 atmospheres above ambient pressure) without significant loss of potency. This reduces the danger of bacterial contamination and simplifies both the preparation of regional block trays and the execution of regional block anesthesia.

The assurance that a local anesthetic solution as well as the equipment employed for its injection is free from contamination prior to performance of a regional block procedure has always been a concern to the physician using these techniques. Heat sterilization of the equipment is now a standard procedure. Unfortunately, there is a misconception that the potency of drugs used to prepare a local anesthetic solution is markedly decreased by heat sterilization. Furthermore, such drugs or solutions purchased in vials or bottles are assumed to be sterile as received from the pharmaceutical firm. Therefore, "cold" sterilization or no resterilization of these drugs prior to injection is the usual routine in many hospitals throughout the United States today.

Cold sterilization is the immersion in antiseptic solutions, e. g., 70% alcohol, of the ampuls, vials, and bottles of drugs and solvents necessary to perform a regional block technique. Cold sterilization is employed primarily to check ampuls of drugs for cracks in the glass which may occur during handling and to sterilize the outside of the ampuls so that they may be placed on a tray that has been sterilized with heat.

It is the purpose of this paper to show evidence that cold sterilization or no resterilization is the routine in many hospitals, to point out the disadvantages of cold sterilization, and to describe the advantages and method of heat sterilization as it is used by us. Furthermore, in our opinion, this study proves that heat sterilization of drugs and equipment under the direction of the physician who is to use them is mandatory.

Method of Study

A questionnaire was sent to all the hospitals in the state of Washington in August, 1957. The questionnaire asked which local anesthetic drugs were used in that hospital; how the drugs were sterilized; and, if cold sterilization was used, which solutions were used. Furthermore, the records of patients to whom regional blocks were administered at the Mason Clinic were reviewed from October, 1953, the date on which we changed from cold sterilization to heat sterilization, to March, 1958.

Results

Of the 121 questionnaires sent to the hospitals, 101 (83.5%) were returned. Of this number only 33 hospitals reported they were autoclaving the drugs used for spinal anesthesia; the remaining 68 hospitals used cold sterilization. The agent used was benzalkonium (Zephiran) chloride, 1:1,000, in 25 hospitals; alcohol in 14; methyldodecylbenzyl trimethyl ammonium chloride solution (C. R. I. germicide) in 5; potassium-mercuric-iodide solution in 2; and miscellaneous in 22. Only two hospitals reported they were autoclaving the multiple-dose rubber-stoppered vials or bottles containing the local anesthetic solutions used for infiltration, field block, caudal block, epidural block, or peripheral nerve block; in the remaining 99 hospitals these multiple-dose vials and bottles were used as received from the pharmaceutical company.

A review of our records indicated that 17,368 regional block procedures had been done since October, 1953 (see table). There was not a single

case of infection or neurological sequelae in any of these cases which could be blamed on the use of unsterile equipment or a contaminated local anesthetic solution.

Regional Block Anesthesias Done at the Mason Clinic from October, 1953, to March, 1958

Procedure	Oct.-Dec., 1953	1954	1955	1956	1957	Jan.-March, 1958	Total
Peripheral nerve block	293	1,087	1,062	971	934	276	4,623
Subarachnoid (spinal) block	137	542	515	628	667	190	2,679
Caudal block	227	1,294	1,523	1,833	2,036	523	7,436
Segmental spinal Epidural block	134	569	534	591	674	128	2,630
Total	791	3,492	3,634	4,023	4,311	1,117	17,368

Comment

The results of the questionnaire survey confirmed our belief that, in a large number of the hospitals in the state of Washington, the ampuls, vials, or bottles of local anesthetic drugs and/or solutions for regional block procedures were not being autoclaved prior to use. It was surprising that so many workers were still using cold sterilization for spinal anesthetic drugs.

Heat sterilization has the following advantages over cold sterilization [1]: 1. The drugs, together with the syringes, needles, and necessary equipment, can be sterilized in the block trays. This avoids the opportunity for contamination by use of an unsterile pick-up forceps for transferring the ampul from the jar to the block tray or use of an unsterile file for opening the ampul. Also, it avoids dripping of the sterilizing solution onto the equipment to be used for the block.

2. The possibility of a contaminated solution dispensed by the manufacturer is eliminated.

3. Heat colors, dissolves, or evacuates the crystals or solution of the local anesthetic drug or other agent should there be a small, invisible crack in the sealed ampul. The neurolytic solutions employed in cold sterilization can gain entrance into the ampul in small quantities not detectable even though no discernible cracks are found in the ampuls.

4. Gummed labels are sterilized. This is not true when cold sterilization is used, since the antiseptic solution does not penetrate through gummed labels used to identify ampuls or under rubber bands used to hold ampuls together.

5. Last, but probably most important, heat sterilization forestalls the legal charge of neglect. The most convincing argument for heat sterilization of local anesthetic drugs was in the legal decision of Wooley and Roe versus Ministry of Health of Great Britain, Dr. Graham, and others.[2] In this case two men, who were paralyzed after spinal anesthesia, were suing for negligence because the physician administering the subarachnoid block had soaked the ampuls in phenol prior to use instead of autoclaving them. During the trial, Dr. MacIntosh testified that in 1953 the best way of sterilizing ampuls was by autoclaving. Lord Justice Denning stated, "Dr. Graham sought to escape the danger of infection by disinfecting the ampoule. . . . He did not know that there could be undetectable cracks, but it was not negligent for him not to know it at that time. We must not look at this 1947 accident with 1954 spectacles. . . . But we have been warned . . . and to keep ampoules in solution, until further evidence is forthcoming, in the future will be regarded legally, as negligence."

Because of the literature extolling the virtues of heat sterilization and because this legal decision was well known, the following routine for cleaning and sterilization of equipment, drugs, and solvents used to prepare local anesthetic solutions was established in our institution in October, 1953.[3]

1. The needles, syringes, and solution cups are washed with copious amounts of clear tap water and rinsed with ether. Detergents are not used.[4] 2. The stainless steel trays for regional block anesthesia, containing the equipment, drugs, and solvents, are prepared (fig. 1). 3. A sterilizer control (Diack) is placed in each tray as it is wrapped. 4. The trays are then autoclaved at 225 to 260 F under 18 to 22 lb. of pressure for 30 minutes.

5. When the tray is dry it is removed from the autoclave and stored on a shelf away from all solutions. This point is stressed, for if solutions are unsuspectedly spilled on the tray it may become contaminated even though the sterilizer control in the tray shows adequate sterilization when it is checked (fig. 2). 6. Reserve ampuls of drugs for all regional block procedures are placed in test tubes which are sealed. Extra bottles of saline solution and

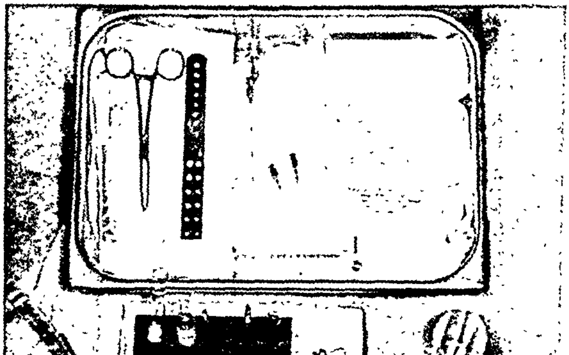

Fig. 1.—Stainless steel tray for regional block anesthesia, containing equipment, drugs, and solvents necessary for subarachnoid block.

vials of commercially prepared local anesthetic solutions too large to fit in test tubes are wrapped individually, together with a sterilizer control, and heat sterilized. Both test tubes and wrapped bottles and vials are stored in a special cabinet (fig. 3). Thus, sterile drugs, solvents, and commercially prepared local anesthetic solutions are always available to replace ampuls in the block trays which have been broken or have evaporated.

We never use hospital-prepared solutions for any regional block procedure. Even the commercially prepared solutions are autoclaved prior to use. Furthermore, all multiple-dose vials are resterilized after being used and before the remaining solution is injected into another patient. Although very few of our colleagues observe this practice and have ridiculed us for this added precaution, its importance was impressed on us in March, 1958, when we received a shipment of 50-cc. multiple-dose ampuls of a local anesthetic solution which had somehow slipped out of the drug company without being sterilized. This was not recognized by the pharmaceutical house until the drug had been in our possession for a number of days. Had this drug been used without our autoclaving it, the troubles it could have created are obvious.

Our experience has shown that the following drugs can be autoclaved at 255 to 260 F under 18 to 20 lb. of pressure for 30 minutes at least once without sufficient loss of potency to alter the expected clinical results: tetracaine (Pontocaine) hydrochloride crystals; tetracaine, 1% solution; procaine (Novocain) hydrochloride crystals; procaine, 1 and 2% solutions; propoxycaine (Blockain) hydrochloride, 2% solution; piperocaine (Metycaine) hydrochloride, 1.5% solution; chloroprocaine (Nesacaine) hydrochloride, 1, 2, and 3% solutions; ephedrine sulfate; methamphetamine (Methedrine) hydrochloride; methoxamine (Vasoxyl) hydrochloride; epinephrine (Adrenalin), 1:1,000; phenylephrine (Neosynephrine) hydrochloride; 10% dextrose solution; dibucaine (Nupercaine) hydrochloride; and lidocaine (Xylocaine), 1 and 2% solutions.

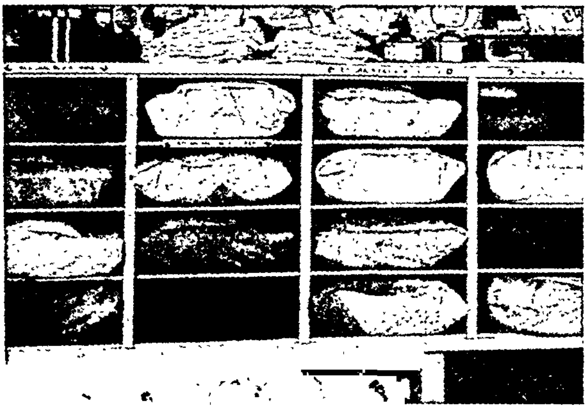

Fig. 2.—Storage space for sterilized trays for regional block anesthesia. Note separate enclosed cubicles to prevent contamination of trays by solutions unsuspectedly spilled on them.

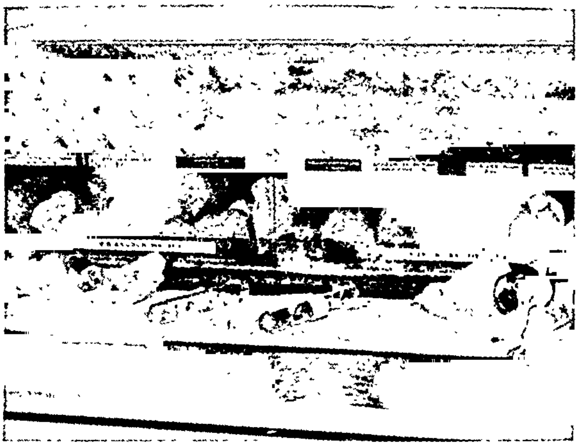

Fig. 3.—Enclosed storage cabinet for test tubes containing reserve ampuls of regional block drugs.

Ammonium sulfate (Dolamin) solutions, oil solutions for local anesthesia (such as Proctocaine), and absolute alcohol can be heat sterilized.[1a] Hyaluronidase cannot be autoclaved at all. Most laboratory tests have demonstrated that the potency of the local anesthetic drugs and solutions, as well as that of vasoconstrictor drugs, is decreased slightly after one or two heat sterilizations, but this small decrease does not affect the clinical results of the drug.[5] On the other hand, more than one or two sterilizations may cause marked decrease in potency, but most figures as to the amount of decrease do not agree.[6]

Summary and Conclusions

If the practice of medicine in the state of Washington can be considered representative of the practice in the United States, then the results of a poll taken in August, 1957, would show how few physicians today appreciate the necessity for heat sterilization of all local drugs, solvents, commercially prepared local anesthetic solutions, and equipment.

The system of heat sterilization used by us in preparing drugs and equipment for regional block procedures has been successful in simplifying the preparation of regional block trays as well as the execution of regional block procedures. The danger of bacterial contamination has been reduced and the danger of antiseptic solution entering a cracked ampul eliminated. Should a neurological complication occur, at least these possible causes have been automatically eliminated. Considering the finality and seriousness of complications after regional block procedures, particularly subarachnoid block, and the large court judgments which have been awarded recently, we conclude that all the local anesthetic drugs, solvents, and commercially prepared local anesthetic solutions, as well as equipment, should be heat sterilized under the direction of the responsible physician prior to their use if freedom from contamination is to be assured.

ELECTROMYOGRAM IN EVALUATION OF NEUROLOGICAL COMPLICATIONS OF SPINAL ANESTHESIA

Albert A. Marinacci, M.D.
and
Cyril B. Courville, M.D., Los Angeles

Some assume that spinal anesthesia is responsible for the development of any concurrent neurological manifestations. Of 482 patients whose neurological complaints seemed to be related to spinal anesthesia, 478 showed neurological complaints due to some other concurrent and entirely unrelated conditions imitating actual complications of the spinal anesthetic agent. In the majority of instances, the causative disease proves to be either an infectious neurönitis or a peripheral neuropathy. The electromyogram plays a fundamental role in the evaluation of these complications. Differentiation in the two groups of lesions is based on the following two basic elements: (1) the distribution of the denervation, that is, electromyographic changes, and (2) the time in which the denervation activity is first detected electromyographically. The prevention of misunderstanding about spinal anesthesia is of great importance.

Muscular weakness or actual paralysis, with concomitant root pains, sometimes follows the administration of spinal anesthesia. The implications involved in this situation are so serious as to demand immediate and careful diagnostic attention. Because of the ever-increasing consciousness on the part of the public that legal action often results in large awards, anesthetists, surgeons, and hospital administrators must always be on their guard to evaluate correctly the cause in each individual case. This situation almost invariably produces a tense emotional atmosphere which leads the patient to blame either the anesthetist or the surgeon for the complications. This is especially the case if there is any delay in accounting for the paralysis. When, after surgery with use of spinal anesthesia, the patient is paralyzed in one or both lower extremities, the following questions present themselves: 1. Is the resulting paralysis a genuine motor disability or is

Ammonium sulfate (Dolamin) solutions, oil solutions for local anesthesia (such as Proctocaine), and absolute alcohol can be heat sterilized.[1a] Hyaluronidase cannot be autoclaved at all. Most laboratory tests have demonstrated that the potency of the local anesthetic drugs and solutions, as well as that of vasoconstrictor drugs, is decreased slightly after one or two heat sterilizations, but this small decrease does not affect the clinical results of the drug.[5] On the other hand, more than one or two sterilizations may cause marked decrease in potency, but most figures as to the amount of decrease do not agree.[6]

Summary and Conclusions

If the practice of medicine in the state of Washington can be considered representative of the practice in the United States, then the results of a poll taken in August, 1957, would show how few physicians today appreciate the necessity for heat sterilization of all local drugs, solvents, commercially prepared local anesthetic solutions, and equipment.

The system of heat sterilization used by us in preparing drugs and equipment for regional block procedures has been successful in simplifying the preparation of regional block trays as well as the execution of regional block procedures. The danger of bacterial contamination has been reduced and the danger of antiseptic solution entering a cracked ampul eliminated. Should a neurological complication occur, at least these possible causes have been automatically eliminated. Considering the finality and seriousness of complications after regional block procedures, particularly subarachnoid block, and the large court judgments which have been awarded recently, we conclude that all the local anesthetic drugs, solvents, and commercially prepared local anesthetic solutions, as well as equipment, should be heat sterilized under the direction of the responsible physician prior to their use if freedom from contamination is to be assured.

1118 Ninth Ave. (Dr. Bridenbaugh).

ELECTROMYOGRAM IN EVALUATION OF NEUROLOGICAL COMPLICATIONS OF SPINAL ANESTHESIA

Albert A. Marinacci, M.D.
and
Cyril B. Courville, M.D., Los Angeles

Some assume that spinal anesthesia is responsible for the development of any concurrent neurological manifestations. Of 482 patients whose neurological complaints seemed to be related to spinal anesthesia, 478 showed neurological complaints due to some other concurrent and entirely unrelated conditions imitating actual complications of the spinal anesthetic agent. In the majority of instances, the causative disease proves to be either an infectious neuronitis or a peripheral neuropathy. The electromyogram plays a fundamental role in the evaluation of these complications. Differentiation in the two groups of lesions is based on the following two basic elements: (1) the distribution of the denervation, that is, electromyographic changes, and (2) the time in which the denervation activity is first detected electromyographically. The prevention of misunderstanding about spinal anesthesia is of great importance.

Muscular weakness or actual paralysis, with concomitant root pains, sometimes follows the administration of spinal anesthesia. The implications involved in this situation are so serious as to demand immediate and careful diagnostic attention. Because of the ever-increasing consciousness on the part of the public that legal action often results in large awards, anesthetists, surgeons, and hospital administrators must always be on their guard to evaluate correctly the cause in each individual case. This situation almost invariably produces a tense emotional atmosphere which leads the patient to blame either the anesthetist or the surgeon for the complications. This is especially the case if there is any delay in accounting for the paralysis. When, after surgery with use of spinal anesthesia, the patient is paralyzed in one or both lower extremities, the following questions present themselves: 1. Is the resulting paralysis a genuine motor disability or is

it to be accounted for on a psychogenic basis? 2. If the paralysis is the result of a true nerve lesion, is such lesion located in the spinal cord, the spinal nerve roots, the corresponding plexus, or the peripheral nerves? 3. If such lesion is located in the spinal cord and/or the spinal nerve roots, is the anesthetic agent its actual cause or is it due to some preexisting or concurrent but unrelated disease? 4. If, on the other hand, the symptoms and signs point to the nerve plexuses and/or the peripheral nerves, is there but one nerve affected (mononeuropathy) or are several of the peripheral nerves involved (polyneuropathy)? 5. Can the etiology be proved with reasonable medical certainty? 6. Can one determine whether the mononeuropathy and/or the polyneuropathy occurred before, during, or after the spinal anesthesia was given? If one can be certain of the exact location as well as of the time of onset of the disease, one can usually come to a correct conclusion and, hence, whether it is actually a complication due to the spinal anesthetic agent or to the surgical procedure.

It is therefore fundamental to the problem to establish these facts. It is just at this point that the electromyogram becomes a useful adjunct to the investigation, as pointed out by Weddell and coworkers in 1944,[1] one of us in 1955,[2] Buchthal in 1957,[3] and Eaton and Lambert in 1957.[4] This has been proved in the past few years, when the electromyogram was used to evaluate a large series of patients of this type presumed to be suffering from postanesthesia neurological complications. Experience derived from a study of these cases clearly indicates that often what were apparently postanesthesia complications were actually due to other concomitant lesions.

In this study, we propose (1) to note the medicolegal aspects of alleged postanesthesia and postsurgical neurological complications, (2) to review briefly what is known about the cause and effects of true neurological complications of spinal anesthesia, (3) to point out the nature of certain simulators of postanesthesia complications particularly of acute infectious neuronitis, (4) to show how the electromyogram is of value in distinguishing between true complications and such imitators, and (5) to indicate the double aspect of spinal anesthesia complications.

Medicolegal Aspects

Out of thousands of patients who have had spinal anesthesia, one may have a profound neurological complication, such as paraplegia of both lower extremities with loss of sphincter control. This rare calamity has created a state of apprehension in medical attendants, including anesthetists, surgeons, consultants, hospital attendants, and administrators, as well as in the general public and, in particular, the patient himself when spinal anesthesia is involved. This situation comes to light whenever any degree of muscular weakness or paralysis follows an operation on a patient under spinal anesthesia, whether these motor symptoms are psychological or pathological in origin. It is clear that, in some cases, the spinal anesthesia has been erroneously incriminated even though a paralysis, such as a foot drop, has occurred weeks after the patient has been discharged from the hospital.

The genuine complications, although rare, have created fertile soil for the unscrupulous members of the legal profession to take advantage of the dictum *res ipsa loquitur.* The anxious patient who finds himself with either muscular weakness or paralysis after spinal anesthesia will naturally ask the doctor what has happened. He complains, "I walked into the hospital and, after the surgery, I am now unable to move my legs." The embarrassed surgeon, as well as the consultant, usually finds it difficult to give the patient a satisfactory answer. In an attempt to answer the patient's inquiry, the surgeon may say, "Possibly I damaged a nerve at surgery; your paralysis may be the result of the spinal anesthesia; you have developed poliomyelitis; or you are imagining your paralysis." The seeds of uncertainty are thereby planted in the minds of the patient and his family. It is usually not difficult to find a member of the legal profession who consciously or unconsciously waters the ground now well fertilized by the already emotional situation. This creates a crop of evil results for the patient, because of lack of proper diagnosis and prognosis, with failure to institute proper treatment. The doctor should learn to say, "We shall find out, but at the present time I do not know." This more positive approach would make the patient more cooperative with the doctor in arriving at the proper diagnosis and proper treatment. It is even possible in most instances to give a favorable prognosis.

This situation can be solved in most cases by the doctors' refraining from expressing divergent opinions and speculative diagnoses and by their securing proper neurological advice and the help of a competent electromyographer. In most instances, the simulators of complications of spinal anesthesia can promptly be brought to light. Such a distinction will benefit most of the patients in that the correct diagnosis and, eventually, full recovery can be achieved.

Pathology of Intraspinal Complications

It has been clearly shown by one of us[5] that certain complications affecting the meninges, nerve roots, and the spinal cord may occur as a result of spinal anesthesia. Although such complications are relatively rare, at least in the United States, the residuals are so serious as to demand careful attention by the anesthetists. It is still uncertain whether these complications are the result of a concentration of the anesthetic agent or whether they occur as a consequence of an irritative product (detergent) injected into the spinal canal along with the anesthetic drug. The number of reported cases in which the intraspinal lesion has been verified at operation or at autopsy is still relatively small. From verified cases, however, it has been shown that the lesions responsible for the clinical symptoms are somewhat variable.

Cauda Equina Syndrome.—The cauda equina syndrome is characterized by a permanent paresis or paralysis of the bladder and/or rectal sphincters *associated with persistent impairment of sensation* of the perineal region. In acute cases, the local meninges and nerve roots are observed to be swollen and markedly congested and the nerve fibers of these roots show early degeneration in the form of vacuolization, as shown by Ferguson and Watkins in 1938.[6] The causative lesion, as ultimately found at autopsy by one of us (C. B. C.), has been marked atrophy of the lower nerve roots of the cauda equina. There is some uncertainty as to whether an isolated peripheral neuropathy can actually occur as a complication of spinal anesthesia. While this cannot be entirely excluded, the possibility of such a neuropathy being due to some other coincidental disease seems to be more likely. Local adhesions of the meninges to the roots of the cauda equina may also be present and found to involve higher levels of the spinal cord.[5]

Chronic Radiculitis.—Multiple chronic radiculitis as a consequence of spinal anesthesia is probably more common than is appreciated. The development of arachnoidal adhesions can evidently be a slow process, as in this condition, resulting from other causes. Weeks or even months after the spinal anesthesia, the patient begins to experience root pains, often scattered at various levels of the spinal cord. Radicular pain, focal paralysis, and atrophy are the common clinical complaints, with motor root involvement being verified by the electromyogram. The lesion begins apparently as an aseptic meningitis which may either clear up spontaneously within two weeks or continue as a chronic form with adhesion formation, as pointed out by Thorsen in 1947.[7] The presence of such adhesions is usually verified by exploration. Both the subdural and subarachnoid spaces may be obliterated with thickening of the meninges.[8]

Myelopathy.—Myelopathy after spinal anesthesia constitutes the *most serious* type of complication as far as the lesion is concerned, being manifest clinically by paraplegia of variable degrees with anesthesia more or less complete up to the level of the cord damage. At times the level may be betrayed by irritative root manifestations. However, multiple foci of root damage may be found by the electromyogram. There are two possible postanesthesia spinal cord lesions: (*a*) acute and (*b*) chronic. The acute lesion may be due in part to severe shock; this seemed to be the chief cause of death in one case as verified by one of us.[5] The lesion proved to be an acute total necrosis of the gray matter of the spinal cord. Such lesions must be extremely rare, for no reports of similar cases have come to our attention.

Chronic myelopathy resulting from spinal anesthesia is a pathological complex with both primary and secondary pathogenic factors. It seems obvious that the external adhesions with involvement of the spinal roots are the direct and immediate effect of the agent (or some concomitant substance) on the *limiting leptomeninges with thickening and opacity* of this membrane. This process is manifest visibly by the formation of adhesions which bind the arachnoid to the pia mater and to the dura mater. Externally, it seems able also to provoke an inflammatory reaction of the dura, with thickening of this membrane. As the process tends not only to spread to higher levels of the cord but also to become accentuated by the contraction of the scar, the disordered local circulation leads to secondary damage of the underlying nervous tissues themselves. The occurrence of peripheral demyelinization of the spinal cord was first demonstrated experimentally by Spielmeyer in 1908[9] and verified in man by one of us in 1955.[5] It is possible that this is a transitory and reversible phenomenon, a possible functional disturbance in the external circulation. Ischemia of the tissues leads to softening of the peripheral portions of the cord, as shown by Brock and associates in 1936,[10] with replacement gliosis if the damage is incomplete. This process seems to be the result of changes in the arterial blood supply, possibly initiated by vasospasm, but ultimately it *is due to structural changes in the arterial wall*—"necrosing arteritis."[11] Perhaps facilitated by the pulsating action of the fluid column on the softened and immobilized spinal cord, central cyst formation develops on the disintegrating cerebral gray matter, adding further to the picture of gross disability.

Although the pathogenesis of the ultimate effects of spinal anesthesia is not completely understood, there can be no doubt that serious irreversible lesions sometimes result. Whether it is the effect of the anesthetic agent itself or of some irritant (alcohol, soap, or detergent) introduced with it is not yet clear. The fact remains that the clinical symptoms as well as the physical effects indicate that the earliest changes are to be expected in the spinal nerve roots, especially those of the cauda equina, with fairly obvious typical pain and a peripheral type of motor disability (weakness and atrophy). It is for this reason that the use of electromyography is of such importance in the early evaluation of an actual or alleged complication. After the secondary and delayed effects of cord involvement become manifest, the diagnosis is rarely in doubt.

Simulators

In this present investigation it has been shown that, with the aid of the electromyogram, many conditions may be concurrent during the period of surgery with use of spinal anesthesia. Such disorders have given rise to symptoms which often simulate or imitate the actual complications of spinal anesthesia. These simulators have almost invariably misled the clinician to incriminate the spinal anesthesia as the cause of the neurological manifestations. These simulators will be discussed in the following paragraphs in the order of their similarity to the problem. They are as follows: (1) acute infectious neuronitis or polyneuritis, (2) preexisting pressure neuropathy, (3) traumatic nerve injury as a direct result of surgery, (4) pressure on the nerve either while the patient is on the operating table or during the period of recovery, (5) pressure neuropathy while the patient is convalescing in the hospital or at home, (6) toxic plexitis, particularly that due to horse serum reaction, (7) progressive spinal muscular atrophy, (8) the myopathies and myotonia, (9) recurrent multiple sclerosis, (10) disuse atrophy, and (11) hysteria.

Acute Infectious Neuronitis.—As one of us and Rand reported in 1956,[12] acute infectious neuronitis can be a perfect imitator of lesions residual to spinal anesthesia. This is because neuronitis is an inflammation of the entire neuron, including the nerve roots and the nerve cells within the spinal cord. Because the anesthetic agent also affects these structures, it is not difficult to understand the similarity of symptoms.

Neuronitis can produce both a reversible and an irreversible reaction in the neuron. In the reversible transitory state, the manifestations can be of three types: (1) pure sensory, (2) pure motor, and (3) sensory and motor combined. In this reversible state, the mild inflammatory reaction and vascular changes probably produce an edema. However, the insult is not sufficiently severe to produce destruction of the nerve cells or of its axons. Therefore, within a period of days the patient has fully recovered. The disease in such a case produces only a transitory physiological block and manifests itself in the form of pure sensory, pure motor, or a combination of both phenomena. The sensory symptoms are manifested by severe radiating pain in the corresponding dermatome. If the disease occurs at the midthoracic level, the resulting pain may simulate that of acute gallbladder disease or peptic ulcer. If the disease attacks the lower thoracic nerve roots, it can simulate either an acute appendicitis or an acute intestinal disorder. If the upper lumbar roots are affected, a surgical lesion of the kidneys is suggested. If the lower lumbar or sacral roots are involved, the acute pain in the lower part of the back naturally imitates a lumbar herniated disk. Perhaps another reason for the resemblance to spinal anesthesia complications is the tendency for both conditions to affect the lower group of spinal nerve roots rather than those of the upper thoracic and cervical ones. This confusion of entities probably accounts for a variety of cases in which the surgeon is disappointed at surgery to find little or no gross changes to account for the severe symptoms. If the operation is done and the spinal anesthesia given when the changes incidental to neuronitis are reversible, it is to be assumed that a natural course of recovery follows. This will occur in patients with the combination of sensory and motor phenomena, as well as in those with either the sensory or the motor phenomenon alone.

On the other hand, when the sensory-motor combination is due to an irreversible lesion, that is, when the disease has produced a degree of actual degeneration of the cells and their axons, the situation will be much more serious. The severe pain will continue and will be followed by paralysis. When this takes place during the postoperative period when the anesthetic agent should be wearing off, the persistence of paralysis raises the question of its origin in the anesthetic agent.

Another serious aspect of this disease is when the infection involves the medullary substance of the spinal cord, producing a form of myelitis, in which case the total picture is then identified as a neuromyelitis. Less frequently, the inflammation also affects the brain itself; this is referred to as neuromyeloencephalitis. These cases are usually fatal. One case in particular during its sensory phase presented acute local symptoms of a typical L-4 herniated disk. The opaque myelogram showed some defect, supporting the diagnosis of such a lesion. However, routine electromyographic evaluation showed, instead of a nerve root compression, diffuse changes from head to foot, including the cranial nerves, all the paraspinal muscles from C-2 through S-5, and all four extremities. Because of the electromyographic findings, the contemplated laminectomy with use of spinal anesthesia was postponed. Within two days, the patient became completely paralyzed. This was followed by central respiratory difficulties. The patient survived in a respirator for two weeks and finally died. If the laminectomy with spinal anesthesia had been done as contemplated, certainly the paralysis and rapidly progressive course which followed would have been attributed to a tragedy of spinal anesthesia complications. It is apparent that when this has happened it has been reported in the literature as acute necrosis of the central gray matter as a possible type of complication of spinal anesthesia.

Clinically, acute infectous polyneuritis resembles grossly a neuronitis. However, there can be one main specific difference between the two: the spinal fluid protein level is normal in polyneuritis while in neuronitis it is usually elevated with a normal cell count. Although the electromyographic changes vary in these disease entities, that is, in neuronitis the paraspinal muscles are involved in addition to the lower extremities and in polyneuritis only the lower extremities are involved, nevertheless when the paralysis is limited to one or both lower extremities it is also a perfect imitator of the complications of spinal anesthesia.

Preexisting Pressure Neuropathy.—Pressure neuropathy can occur before the patient comes to the hospital. He may have been either under the influence of drugs or alcohol or in an unconscious state due to various causes. This situation results in a complete relaxation of the muscles, thus leaving the nerves unprotected and producing an ideal condition for pressure neuropathy. Certain nerves are liable to pressure because of their anatomic accessibility. For example, the leg hanging over the side of the bed exerts pressure on the sciatic nerve. Prolonged crossing of the legs exerts pressure on the peroneal nerve at the head of the fibula. When the leg is dangled over a chair, pressure is created on the tibial nerve at the popliteal fossa. Overabduction can stretch the obturator nerve at its bony emergence. When the patient hangs an arm over a chair, pressure is exerted on the ulnar and median nerves at the middle of the arm. The presurgical neuropathies have been encountered in acute gastric conditions, such as perforated peptic ulcer, pancreatitis, acute gallbladder disease, acute intestinal obstruction, acute appendicitis, such gynecologic conditions as ectopic pregnancy, and induced abortion with profuse bleeding. An undetectable paralysis, already present, becomes apparent as the patient recovers from surgery. The persistence of the paralysis is usually alleged to be the result of a complication of spinal anesthesia.

Traumatic Nerve Injury.—Traumatic nerve lesions as a direct result of surgery have been observed in a few patients.[13] A few cases have been seen of the nerve being actually damaged during surgery but which imitated the complications after spinal anesthesia. The femoral nerve was severely damaged during hernia repair in two patients. This nerve has been partially damaged in eight cases during pelvic surgery. The paralysis in these cases not being present before surgery, the spinal anesthesia has invariably been incriminated for the neurological complication. If the lesion is preexistent, the denervation will be present during the first two postoperative weeks. If this paralysis is the result of the surgical procedure, the changes will not appear until 21 days after surgery. A partial nerve lesion can be demonstrated with the aid of the electromyogram in the presence of complete paralysis. Such favorable information gives the patient a considerable amount of psychological relief when he is informed that the paralysis is not a complication of spinal anesthesia, that the nerve was not cut during surgery as was possibly suggested by medical attendants, and that he will eventually recover from his paralysis. This favorable information has usually dissipated any contemplated medicolegal action.

Pressure Neuropathy During Surgery.—Pressure on the nerve during the period of surgery and/or recovery period has been observed rather frequently.[13] In this condition, denervation activity will be limited to the muscle group innervated by the affected nerve. The electromyographic changes will appear in the fourth postoperative week. Here again, these pressure neuropathies have imitated the complications of spinal anesthesia, but the distribution of electromyographic changes are those of a mononeuropathy and not those of cauda equina radiculopathy. The nerve lesion which most resembles the complication is that of the sciatic nerve caused by either intramuscular injection in the gluteal region or pressure at the gluteal fold. Both femoral and obturator nerves have been found to be liable during extreme abduction during vaginal or rectal procedures. Also, the obturator nerve has been found stretched when the leg was allowed to be in an extreme abductive position while the patient was in an unconscious state. The peroneal nerve is liable to pressure at the head of the fibula, resulting in a foot drop. Cases have been seen in which pressure on the tibial nerve at the popliteal fossa has occurred, resulting in muscular weakness and atrophy of the calf and foot. In addition, bilateral pressure on the ulnar nerve resulting in muscular wasting of both hands brings a cervical or upper thoracic lesion into consideration and has simulated chronic adhesive arachnoiditis.

The electromyographic changes in all these cases are to be found three weeks after the actual date of the surgery. However, one can not definitely state whether such pressure took place one or two days before, during, or immediately after surgery. One can definitely state that the affection is not the result of the surgical procedure if such a lesion is not within the area of the surgery, such as a peroneal nerve involvement (foot drop) after abdominal surgery. On the other hand, the spinal anesthesia in these cases cannot be incriminated, regardless of the date of appearance of the electromyographic changes, for the simple reason that the paraspinal muscles are normal.

Pressure Neuropathy During Convalescence.—Pressure neuritis during the convalescent period can occur either in the hospital or after the patient returns to his home.[14] The muscular weakness or paralysis has been alleged to be the direct result of spinal anesthesia complication. This type of neuropathy often occurs when the patient stays in bed reading for long periods of time; the exertion of pressure at the elbows produces changes in the ulnar nerves, resulting in muscular wasting of the hands. Occasionally, this condition has been interpreted clinically as the progressive widespread spinal cord changes which are seen in chronic progressive adhesive arachnoiditis.

Patients have also been observed who had peroneal and tibial nerve lesions resulting from either prolonged crossing of the legs or dangling of the legs while sitting in a rocking chair in the hospital or at home (viewing television). Here again the spinal anesthesia has been incriminated.

Toxic Plexitis.—Toxic plexitis is most frequently the result of a horse serum reaction from tetanus antitoxin injection. However, occasionally it is seen in other toxic reactions after an extremely high fever. The factor in this lesion which simulates the complications of spinal anesthesia is that the clinical muscular weakness or paralysis does not appear until about 10 days after the injection. Patients who have had surgery under spinal anesthesia during this intermediate period and whose paralysis appears during the postoperative period have erroneously incriminated the surgical or spinal procedure for the neurological complications. This has been especially true when the reaction was severe, involving not only the cervical and brachial plexuses but, to lesser degree, the lumbosacral plexuses as well. In these cases, the electromyographic changes are essentially peripheral, with no specific changes in the paraspinal muscles. This characteristic distribution rules out the complications due to the anesthetic agent, regardless of the time when the electromyographic changes are detected. When this condition is unmasked, naturally the patient who is apprehensive about the complications of spinal anesthesia is relieved when informed that he will recover eventually from his paralysis. This positive statement gains the proper cooperation from the patient for treatment and also can eliminate the possibly contemplated medicolegal action.

Spinal Muscular Atrophy.—Progressive spinal muscular atrophy has at times simulated spinal anesthesia complications. This condition in patients in whom the manifestations become gradually apparent, especially in the lower extremities, can simulate a lumbar herniated disk, as shown by Shea and co-workers in 1950.[15] A few of these patients have undergone laminectomy under spinal anesthesia. The subsequent progressive muscular wasting of both lower extremities has imitated the complications of spinal anesthesia. This disease not only simulates cauda equina radiculopathy but, as it progresses, also involves the upper extremities. The resulting clinical picture imitates chronic adhesive arachnoiditis. Although the clinical manifestations may be limited to the lower extremities, the electromyographic changes are plurisegmental in distribution and are accompanied by pathological fasciculations. The changes are detected immediately. The distribution of the denervation and the time it is detected differentiates this disease from cauda equina radiculopathy, in which the changes are restricted and will not be detected until three weeks after the spinal anesthesia. Here we have a specific example which illustrates the importance of immediate electromyographic evaluation—as soon as the muscular weakness manifests itself.

Myopathy and Myotonia.—At times, the myopathies and myotonia may simulate complications of spinal anesthesia. Some patients suffering from the distal form of muscular dystrophy, as well as some with myotonia, have claimed that the atrophy and/or muscle spasms were noted after spinal anesthesia. The differential diagnosis is a matter of great simplicity. First of all, no denervation activity is found, but dystrophic and/or myotonic activity are recorded. These findings rule out complications of spinal anesthesia.

Multiple Sclerosis.—Recurrent attacks of multiple sclerosis at times have taken place during the period of spinal anesthesia. The muscular deficit produced by this disease has been thought to be the result of the anesthetic agent. Multiple sclerosis, being an upper motor neuron disease, gives no electromyographic changes. Therefore, spinal anesthesia complications are definitely ruled out.

Disuse Atrophy.—Disuse atrophy, as reported by one of us and Rand in 1958,[16] is the result of lack of use of the voluntary muscles; it has been observed to occur in numerous conditions, especially in hysteria and in bone pathology or upper motor neuron lesions. Again, on occasion, spinal anesthesia has been erroneously incriminated. In these cases, the electromyographic findings are absolutely normal.

Hysteria.—Conversion hysteria, manifested in the form of paralysis of one or both lower extremities, also has imitated complications after spinal anesthesia.

Electromyogram in Differential Diagnosis

In the past few years, the electromyogram has been used by one of us (A. A. M.) to evaluate a large series of patients suffering from muscular weakness or paralysis as caused by a number of neurological conditions. The manifestations were not infrequently alleged to stem from spinal anesthesia. In a large series of cases, this allegation was worthy of critical analysis in 482. With the aid of the electromyogram, the true nature of the situation was unmasked. It is noteworthy that there was evidence of true complications of spinal anesthesia in only 4 patients, while in the remaining 478 the condition was actually due to an unrelated disease. Because the electromyogram plays a fundamental role in the evaluation of these complications, it is only proper that a brief basic résumé of clinical electromyography should be presented.

The present communication is concerned with the profound complications which follow spinal anesthesia and a group of other conditions which simulate it. Differentiation in these two groups of lesions is based on two basic elements: (1) the distribution of the denervation, that is, electromyographic changes, and (2) the time in which the denervation activity is first detected electromyographically.

The precise location of the lesion can be determined by the distribution of the denervation and altered motor units. For example, in true complications of spinal anesthesia,[2] the denervation activity will not be detected until three weeks after the actual administration of the anesthetic agent. The distribution of the denervation activity is uniform and restricted. In a typical case of a true cauda equina radiculopathy, the changes will be found in the paraspinal muscles, the pelvic girdle, and the muscles of both lower extremities, that is, in the muscles innervated from about the level of L-1 down to the first coccygeal nerve root, in the lumbosacral plexuses, and in all the peripheral nerves of both lower extremities. No denervation activity will be found above the level of L-1, in the muscles of the cranial nerves, in the cervical or thoracic nerve roots, or in the peripheral nerves of the upper extremities—arms, forearms, or hands. In short, the changes are uniform in distribution and restricted in area and will appear three weeks after the administration of the spinal anesthesia.

In patients in whom the complications eventually assume the clinical picture of chronic progressive adhesive spinal arachnoiditis,[2] the electromyographic changes will start to appear after the third postoperative week and they will be found in the nerve roots of the lumbosacral region, in the corresponding plexuses, and in the peripheral nerves of the lower extremities. As time goes on, the electromyographic changes gradually assume an ascending trend which finally involves the paraspinal muscles of the thoracic and cervical regions, as well as those of the upper extremities.

The electromyographic changes in virus neuronitis[12] are widespread, involving the paraspinal muscles as well as the extremities. As a rule, the denervation decreases on ascending from the extremities to the muscles of the back. In a typical case, one finds changes in both feet, legs, and thighs, in the pelvic girdle, and in the paraspinal muscles, with the changes in the paraspinal muscles fading out as one approaches the eighth dorsal level. Occasionally, changes are also found in the distal portion of both upper extremities and in the muscles of the face. In spite of uneven widespread electromyographic changes, the patient may complain of weakness or paralysis in the low part of the back and in one or both lower extremities simulating a true complication of a spinal anesthesia. In short, the changes are uneven in distribution and will be detected as soon as the apparent complications manifest themselves.

Patients suffering from acute infections polyneuritis show electromyographic changes in both extremities and no changes in the paraspinal muscles. Here again, the clinical manifestations may be limited in one or both lower extremities, simulating a cauda equina lesion. In short, the changes will be detected immediately and are essentially peripheral in distribution.

Electromyographic changes in involvement of the lumbosacral plexus will, of course, not be found in the paraspinal muscles. They will be present in the gluteal group, the thigh, and the muscles of the leg and foot. The main differential point consists in finding no changes in the paraspinal muscles.

In cases of involvement of the sacral plexus, changes will be present in the gluteal group, the hamstrings, and the muscles of the leg and foot. No changes will be found in the quadriceps or adductor group or in the paraspinal muscles, which rules out a diagnosis of complication of spinal anesthesia.

Lesions of the femoral nerve[17] show denervation activity only in the quadriceps, with none in the paraspinal muscles, which will differentiate such a lesion from the cauda equina in which denervation activity will be found uniformly in the paraspinal muscles as well as in both lower extremities.

A lesion affecting the obturator nerve will show changes confined in adductors. A lesion of the peroneal nerve shows changes only in the muscles innervated by the common peroneal nerve on the side of the leg.

Tibial nerve lesions at the level of the popliteal fossa may also simulate the true complications of spinal anesthesia. However, denervation activity in tibial nerve lesions is confined only in the muscles of the back of the leg and foot. None are found above the level of the knee.

Plantar nerve lesions[18] are now believed to be one of the most misleading of nerve lesions. This lesion has simulated lumbar herniated disk syndrome, for which some patients have had a laminectomy. The persistence or aggravation of the symptoms have been alleged to be the result of postanesthesia complications. The electromyographic changes are confined only in the intrinsic muscles of the involved foot instead of the distribution of the nerve root for which the patient had the surgery.[15]

To sum up, the differentiation between lesions of either the nerve plexuses or the individual peripheral nerves and the complications of spinal anesthesia is that in the complications denervation activity will be found in both the paraspinal muscles and those of the lower extremities while in disorders of the plexuses and of the peripheral nerves the electromyographic changes are confined to the respective muscle groups. Furthermore, if the lesion involving the plexus or the peripheral nerves preexisted the spinal anesthesia for three weeks, the denervation activity will be detected as soon as the complications become apparent. On the other hand, if the lesion occurred during the period of surgery, the electromyographic changes will not be detected until three weeks after the surgery has been done. For this reason, the electromyogram should be done as soon as the complications manifest themselves.

In progressive spinal muscular atrophy, which may be confused with chronic adhesive arachnoiditis, the electromyographic changes will be present as soon as the complications manifest themselves and will be found to be widespread both in the paraspinal muscles and in all four extremities as well, even in the cranial nerves at times. Occasionally a distal form of progressive muscular dystrophy with physical alteration in the muscles of the leg can also simulate cauda equina radiculopathy. The electromyogram will show no denervation activity but, instead, dystrophic activity. Finally, the distal forms of myotonia have sometimes been confused with cauda equina radiculopathy because of the muscle spasms and muscle weakness of the lower extremities. The electromyogram, of course, will show no denervation activity but, rather, only myotonic activity.

Double Aspect of Spinal Anesthesia Complications

It is just as important to anticipate alleged complications of spinal anesthesia as it is to point out the true character of certain imitators of these complications. In other words, prevention of difficulty is just as worthwhile, perhaps even more so, as distinguishing between the true and false when neurological symptoms and signs appear after the anesthetic episode has occurred. The prophylactic aspects of the problem will be discussed first.

The prevention of misunderstanding about spinal anesthesia is so important that any reasonable steps in this direction are worthwhile. Because prodromata of many of the simulators of spinal complications can be suspected if not detected, the prospect for spinal anesthesia should be questioned about any episodes of recent upper respiratory infections, febrile states, vaccination, or the administration of antitoxins. The patient should be asked about the occurrence of neuropathic symptoms—radiating pains, especially in the thoracic, lumbar, or lumbosacral root zones, the presence of abnormal sensations in the form of numbness, tingling, or burning, and the impairment of loss of motor power. The excessive use of alcohol or of sedative drugs leading to stupor or lethargy should be investigated for complications complained of after the anesthesia has been given. An inquiry regarding symptoms suggestive of possible episodes of loss of consciousness, anterior poliomyelitis,[19] multiple sclerosis, progressive spinal muscular atrophy, or myopathy should also be investigated. In case of any doubt or suspicion, a neurological examination, lumbar puncture for possible changes, and, above all, an electromyogram to check on antecedent alteration is of vital importance in avoiding misinterpretation of postanesthesia complaints.

It is needless to urge the necessity of keeping accurate records of actual procedure, the verification of the agent used, the size of spinal needle, and the precise interspace at which the injection was done. A wise precaution in any case would be withdrawal of a few cubic centimeters of spinal fluid for cell count and total protein level before the spinal anesthesia is administered in case of any doubt, particularly because these tests can be done in a short time.

The second aspect of the problem deals with the postanesthesia manifestations which suggest complications. The first step is a consultation with a competent neurologist and the second an immediate and thorough electromyographic examination. The neurologist may bring to light evidence favoring some preanesthesia neurological disease or disorder which can account for the symptoms. He may also delineate a case of malingering or of conversion hysteria. The electromyogram may likewise help by demonstrating the preexistence of lower motor neuron disease, for, if significant changes are found, it may be assumed that such changes were due to a disease already existing at least three weeks prior to the administration of the anesthetic. Moreover, the electromyographic findings may indicate that the causative disorder is not in the anterior horn cells, the motor root, or peripheral nerves but in the muscles themselves. At times, this examination may show that the complication is incidental to the surgical procedure rather than the anesthetic. Spinal anesthesia can be incriminated only when characteristic root manifestations (cauda equina) are found in the lower spinal levels only after three weeks have elapsed. When there is any question as to complications, an electromyogram should be done or even repeated before the patient leaves the hospital. This is to rule out evidence of complications which may actually occur at home but later be charged to the spinal anesthesia. Such a repeat should be done about three weeks after the spinal was done, for, if no changes are present after that interval, the anesthetic agent can be exonerated.

Summary and Conclusions

Out of thousands of patients who have been given a spinal anesthetic only rarely does one develop a neurological complication. Nevertheless, the possibility of such a calamity has created among the laity an apprehension which manifests itself whenever this form of anesthesia is followed by any type of muscular weakness or paralysis. For this reason, it is not uncommon for some to assume that the spinal anesthetic is responsible for the development of any concurrent neurological manifestations. In the recent past, a large series of patients who alleged that muscular paralysis was a direct result of spinal anesthesia have been examined by the electromyogram.

As a basis for this study, 482 patients whose neurological complaints seemed to have some merit were critically investigated. It was rather surprising to learn that evidence of what seemed to be true complications of spinal anesthesia were found in only four patients of this group. In the remaining 478 patients the neurological complaints were due to some other concurrent and entirely unrelated conditions. These conditions had imitated actual complications of the spinal anesthetic agent. On this basis, it would appear that in only 1 of 120 cases (0.82%) did the paralysis actually prove to be due to a genuine anesthetic complication. This experience indicates that the true picture of such complications can be delineated only by competent neurological examination and a complete electromyographic study undertaken by an experienced electromyographer. This comprehensive evaluation of the picture should be undertaken just as soon as the muscular weakness or paralysis becomes apparent. This urgency is based on the observation that the damage to the spinal nerve roots due to the anesthetic agent will not manifest itself on the electromyogram until three weeks after the actual date of the anesthesia. Therefore, if one finds electromyographic changes immediately or soon after the spinal anesthesia, it presumes the preexistence of some other disorder. In the majority of instances, the causative disease proves to be either an infectious neuronitis or a peripheral neuropathy.

Thus, with the aid of the electromyogram it has been pointed out that often some other entirely unrelated condition is responsible for the apparent neurological complications of the spinal anesthesia. These conditions, actually counterfeits of postanesthesia complications, have falsely incriminated the anesthetic agent itself for the paralytic state in almost 99% of the cases examined. The anesthetic agent was actually responsible for the paralysis in about 1% of the patients examined.

CLINICAL NOTES

STAPHYLOCOCCIC ENDOCARDITIS TREATED WITH RISTOCETIN

Robert W. Weber, M.D., Kansas City, Kan.

The treatment of endocarditis caused by Staphylococcus (Micrococcus) pyogenes var. aureus has become a challenging problem; therefore, two patients successfully treated with a new antibiotic agent, ristocetin, are reported on here. In these two patients, the infections were acquired in hospitals and, as might be expected, the staphylococci were resistant to penicillin. Each was critically ill when therapy was started, and the use of ristocetin was associated with prompt clinical improvement and eventual bacteriological cure.

Thrombophlebitis of severe degree developed in both patients and complicated administration of the antibiotic, and severe leukopenia occurred approximately two weeks after the onset of therapy in both patients. These complications cleared after completion of therapy.

Report of Cases

Case 1.—A 32-year-old woman was admitted to the University of Kansas Medical Center on Oct. 9, 1957. She first noted the onset of chills and fever during the afternoon of Sept. 21. The next day, she was admitted to her local hospital and aborted a two-month-old fetus. The chills and fever continued and, two days later, a dilatation and curettage was performed. Initially, she was placed on therapy with penicillin and streptomycin, but she continued to have daily temperature elevations to between 104 and 105 F (40 and 40.5 C). She then received oxytetracycline, chlortetracycline, and novobiocin. During the 19 days in the local hospital, the patient was afrebile for only one six-hour period; this occurred after she was given corticotropin for four days prior to transfer to this hospital.

The history revealed numerous sore throats as a child, but no findings suggestive of rheumatic fever. There was no history of heart disease or of a heart murmur.

At the time of admission to this hospital, the patient complained of chills, fever, and weakness. She also described sharp pain, pleuritic in nature and present for two days, in the left anterior part of the chest.

Physical Examination.—The patient was an obese woman who was pale and appeared acutely and chronically ill. Blood pressure was 120/55 mm. Hg, pulse rate 120 per minute, respiratory rate 28 per minute, and temperature 101.6 F (38.6 C). Numerous hemangiomas were present over the anterior part of the chest and upper extremities. No petechiae were seen in the conjunctiva or elsewhere over the body. Rales were present in both lung bases and in the left anterior apical area of the lungs. The heart was enlarged to percussion. There was a gallop rhythm at the apex, and a grade 2 systolic murmur was present in the third interspace to the left of the sternum. The liver was palpable at the right costal margin. The spleen was not palpable. Pelvic examination was negative. Pitting edema of the ankles was demonstrated. Findings on neurological examination were within normal limits.

Laboratory Data.—Urinalysis showed a trace of albumin and microscopically many red blood cells and 8 to 16 pus cells per high-power field. The hemoglobin level was 8.7 Gm. per 100 ml., and the white blood cell count was 10,300 per cubic millimeter with 83% neutrophils. Results of serologic testing were negative. The blood urea nitrogen level was 15 mg. per 100 ml., and the blood sugar level was 84 mg. per 100 ml. The sedimentation rate was 33 minutes per hour (Cutler). The C-reactive protein precipitation was 4+, and the antistreptolysin-O titer was 333 units.

The electrocardiogram revealed a P-R interval of 0.16 second, and there was sinus tachycardia with 120 beats per minute. An infiltration was present in the left upper lung field on the roentgenogram, which was characteristic of a pulmonary infarction. The heart size was at the upper limits of normal.

During the first 12 hours after admission, eight blood cultures were obtained. A coagulase-positive, hemolytic Staph. pyogenes var. aureus was grown from each of these cultures, and, quantitatively, 45 to 248 colonies were isolated from each cubic centimeter of blood. The disk type of sensitivity study revealed only moderate sensitivity to erythromycin, chloramphenicol, and nitrofurantoin (Furadantin). Tube dilution sensitivities[1] are recorded in the table.

Tube Dilution Sensitivities, in Micrograms per Cubic Centimeter, in Two Patients Being Treated for Staphylococcic Endocarditis

	Case 1		Case 2	
Antibiotic	Sensitive to	Resistant to	Sensitive to	Resistant to
Erythromycin	0.16	0.08	0.08	0.04
Oleandomycin	0.50	0.25	...	...
Nitrofurantoin	37.50	30.00	...	...
Novobiocin	125.00	100.00	0.30	0.016
Penicillin (units)	1,000.00	500.00	62.50	50.00
Ristocetin	5.00	3.90	3.10	2.50
Chlortetracycline	...	...	0.60	0.30
Streptomycin	...	...	25.00	31.30

Hospital Course.—During the first 24 hours after admission, the patient was digitalized. Her temperature rose to 103.2 F (39.5 C) on Oct. 9 and to 104.6 F (40.3 C) the next day. She complained of pleuritic pain in the left anterior part of the chest, and a friction rub was audible in this area. On Oct. 10, after the eighth blood culture was obtained, novobiocin therapy was started. On Oct. 12, tube dilution sensitivities were available, and that therapy was discontinued. Erythromycin, 2 Gm. every six hours, was then given orally. The temperature curve is shown in fig. 1. Although she became afebrile after receiving erythromycin two days, the fever returned in five days and, clinically, she remained critically ill. Blood cultures were repeatedly negative after erythromycin therapy was begun. On Oct. 25, she complained of severe nausea and vomited after every meal. This continued until Oct. 27, when the erythromycin dosage was decreased to 1 Gm. every six hours. At this time, ristocetin therapy was begun. A "cut-down" (venostomy) on the

---

From the Department of Medicine and Microbiology, University of Kansas School of Medicine.

left small saphenous vein was performed and a polyethylene catheter inserted. Ristocetin, 1.5 Gm., was given intravenously in 500 cc. of 5% glucose in water every eight hours. This was administered in two hours and was followed by isotonic sodium chloride solution or 5% glucose in water given slowly, to maintain the cut-down. Twenty-four hours after starting the ristocetin therapy, the temperature returned to normal. On Nov. 4, the ristocetin dosage was decreased to 1 Gm. every 12 hours, and, on Nov. 8, this therapy was discontinued. The total dose was 44 Gm. Serum concentrations of ristocetin were determined four hours after administration of the antibiotic on four occasions. The levels on Oct. 30, Nov. 1, and Nov. 4 were 80 mcg. per cubic centimeter and on Nov. 7, 40 mcg.

On Oct. 29, thrombophlebitis developed in the left leg and a second cut-down was performed on the right leg. Severe thrombophlebitis also developed in this leg before therapy was discontinued. On Nov. 6, anticoagulant therapy with aqueous heparin and bishydroxycoumarin (Dicumarol) was begun. The thrombophlebitis improved after the institution of this therapy.

As noted in figure 2, the white blood cell count was 3,700 per cubic millimeter, with 71% neutrophils, on Nov. 8, when the ristocetin therapy was discontinued. During the next seven days, the count declined to 1,400, with 4% neutrophils. The eosinophil count did not rise until the white blood cell count and neutrophils increased in number. Specific therapy was not instituted for the neutropenia, and antibiotics were not administered during this period. The hemoglobin level and platelet counts remained unchanged.

After the thrombophlebitis subsided, the patient became afebrile and asymptomatic. The heart murmur was heard with difficulty when she was dismissed from the hospital. Correspondence with her local physician two months after her discharge revealed that the patient had resumed her duties as a housewife.

The origin of the staphylococcic bacteremia in this patient is difficult to establish, and several possibilities exist. Three of her children had recently been hospitalized with sore throats, and a staphylococcic infection may have been acquired from them prior to her hospital admission. Infection may have occurred in the hospital after the abortion and subsequent curettage. Sensitivity studies on the organism which was isolated from the blood cultures would suggest that this was a hospital strain of staphylococcus.

Location of the heart murmur in the second left intercostal interspace and absence of transmission of this murmur into the neck would indicate the pulmonary valve as the site of the endocarditis. Pulmonary embolization, in the absence of demonstrable disease in the peripheral veins, would substantiate this impression. Further evidence was the changing heart murmur after therapy. A murmur had not been described previously, although the patient had been examined repeatedly during six previous pregnancies.

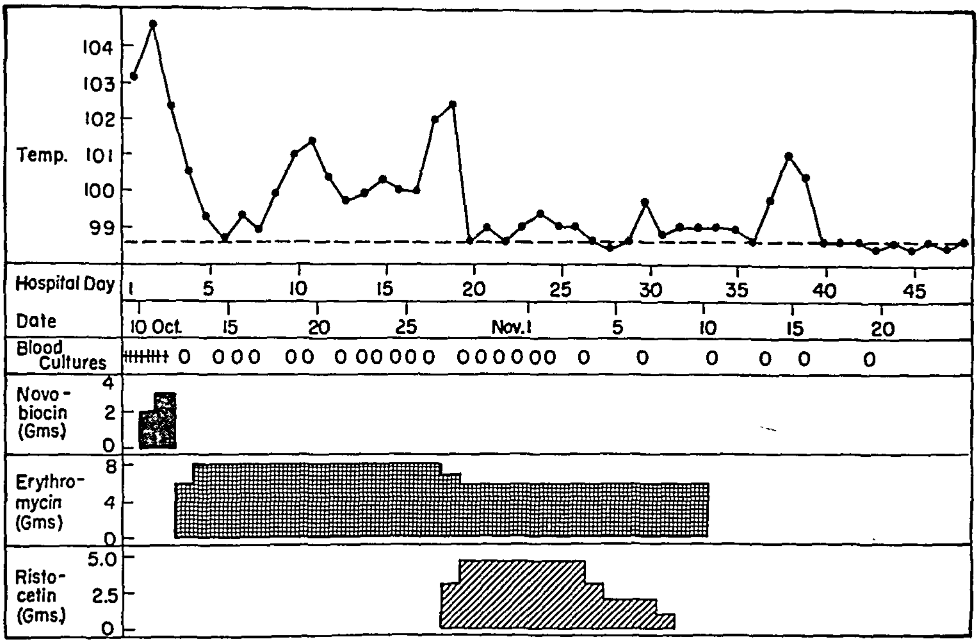

Fig. 1 (case 1).—Temperature curve of patient with staphylococcic endocarditis treated with novobiocin, erythromycin, and ristocetin.

Resistance of this staphylococcus to novobiocin was unusual, but the antibiotic had been administered in inadequate amounts, 750 mg. daily for one week, before sensitivity studies were made. Rantz and co-workers [2] reported a similar experience in a young woman with staphylococcic endocarditis. Their patient received 1 Gm. of novobiocin daily for three days, and, when sensitivity studies were performed later, the organism had increased its resistance to this antibiotic from 0.5 mcg. to 20 mcg. per cubic centimeter. Unfortunately, previous cultures were not obtained in this patient, but it is likely that the resistance developed while she was receiving the antibiotic in relatively small amounts. Novobiocin was given here for only two days and did not affect the clinical course.

Initially, the response to erythromycin was encouraging, but, after five days, clinical deterioration began and fever returned. Previous reports of the ineffectiveness of erythromycin alone in the treatment of staphylococcic endocarditis further emphasized the necessity of use of a second antibiotic agent.[3] Sensitivity studies indicated that ristocetin would be effective, and adequate serum levels were demonstrated after its administration.

CASE 2.—A 21-year-old woman was admitted to the University of Kansas Medical Center on Oct. 7, 1957. She complained of weakness and painful swelling of the joints and muscles.

She was first hospitalized at another hospital, Aug. 19, 1957, because of dysmenorrhea. A laparotomy was performed on Aug. 21, and a corpus luteum cyst was removed. Excessive uterine bleeding occurred after surgery, and curettage was performed on the sixth postoperative day. She became febrile after this procedure and was given penicillin, streptomycin, sulfadiazine, and tetracycline. On Sept. 1, she complained of generalized muscular aching and joint pains. On Sept. 12, an abscess was noted in the left antecubital fossa, and, on Sept. 20, a second abscess was noted in the right antecubital area. The temperature was frequently elevated to 102 to 103 F (38.8 to 39.4 C), and arthralgia and myalgia increased. A muscle biopsy was obtained, and a diagnosis of dermatomyositis was suggested. Corticotropin and cortisone therapy was started on Sept. 27. Although the fever subsided with steroid therapy, other symptoms remained and she was transferred to this hospital while still receiving antibiotic therapy.

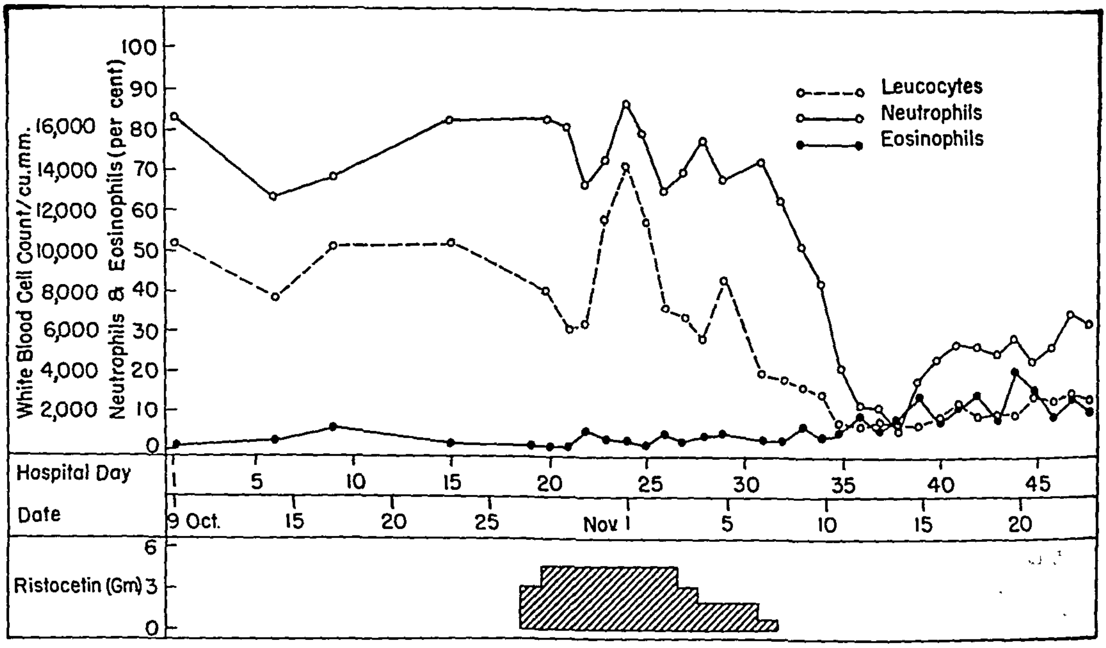

Fig. 2 (case 1).—Effect of ristocetin on leukocyte, neutrophil, and eosinophil counts in patient with staphylococcic endocarditis.

Her history revealed that a diagnosis of acute rheumatic fever had been made in 1954. She described joint pains and fever with this illness. A heart murmur was also discovered at this time. The symptoms disappeared without treatment or bed rest. In 1947, she had pneumonia and, in 1951, an appendectomy. During the previous years in college, she had had numerous respiratory infections characterized by cough and rhinitis.

Physical Examination.—The patient was pale and appeared chronically ill but was in no acute distress. She weighed 125 lb. (58.5 kg.). Blood pressure was 110/60 mm. Hg and pulse rate was 72 per minute and regular. A grade 2, blowing, systolic murmur was heard in the third intercostal interspace, immediately to the left of the sternum, and was transmitted over the base of the heart and into the carotid arteries. A recent, well-healed, suprapubic scar was present. The liver and spleen were not palpable. Minimal pitting edema was present in both lower extremities. The bilateral anticubital abscesses were healing, and pus could not be extracted on pressure.

Laboratory Data.—Urinalysis revealed a heavy trace of albumin, occasional pus, and occasional red blood cells. The hemoglobin level was 12.8 Gm. per 100 ml., and the white blood cell count was 16,000 per cubic millimeter, with 73% neutrophils, 21% lymphocytes, 3% monocytes, and 1% eosinophils. Findings on the Venereal Disease Research Laboratory test were negative. L.E. cells were not observed in peripheral blood. The agglutination test for heterophil antibodies was positive in a 1:14 dilution. The sedimentation rate was 15 mm. per hour. The antistreptolysin-O titer was 12 units. Findings on the electrocardiogram were within normal limits. A normal-sized heart and clear lung fields were seen on x-ray examination. Six blood cultures were obtained, and no growth was observed aerobically or anaerobically.

Hospital Course.—During the next 10 days in the hospital, the maximum daily temperature was between 99.4 and 101 F (37.4 and 38.3 C). The dosage of cortisone was gradually decreased, and therapy with this drug was discontinued on the ninth day. Therapy with antibiotics was discontinued on admission. The patient continued to complain of muscle aching, but no objective findings were observed.

On Oct. 17, 1957, the patient was allowed to go home for four days. On Oct. 21 she returned to the hospital with chills and fever. The temperature was 104 F (40 C). The physical findings were essentially unchanged, and no petechiae were noted. The initial blood culture grew 183 colonies of hemolytic Staph. pyogenes var. aureus, coagulase-positive, per cubic centimeter of blood. Four blood cultures were obtained during the first 12 hours in the hospital, and all were positive.

Therapy with aqueous sodium penicillin G, 5 million units every six hours, was started on Oct. 22, before sensitivity studies were available. Novobiocin, 1 Gm. every six hours, was given the following day on the basis of disk sensitivity study results. A novobiocin blood level of 38.4 mcg. per cubic centimeter of serum was obtained 24 hours after starting therapy with this antibiotic. The tube dilution sensitivity results are recorded in the table.

Novobiocin therapy was continued until Oct. 27, as noted in figure 3, when it was discontinued because the patient developed a generalized erythematous macular rash. Nausea and vomiting also occurred frequently after this medicament was given. On Oct. 26, petechiae were first noted on the abdomen. Therapy with erythromycin, 1 Gm. orally every eight hours, and ristocetin, 1 Gm. intravenously every six hours in 500 cc. of 5% glucose in water, was begun when that with novobiocin was discontinued. It was necessary to insert a polyethylene catheter into the small saphenous vein to give the intravenous therapy. Within two days, thrombophlebitis developed in this leg, but therapy with ristocetin was continued because, clinically, the patient was improving. Bishydroxycoumarin therapy was started on Nov. 2. The pain and swelling increased, and, on Nov. 5, a cut-down was performed on the right leg. On Nov. 3, the ristocetin dosage was decreased to 2 Gm. daily, and therapy with this drug was discontinued on Nov. 11. The right leg also became acutely tender along the saphenous vein, and marked swelling occurred. The thrombophlebitis subsided slowly, and the patient remained febrile until it resolved. Erythromycin therapy was continued until Nov. 27, but it had no apparent effect on the temperature course.

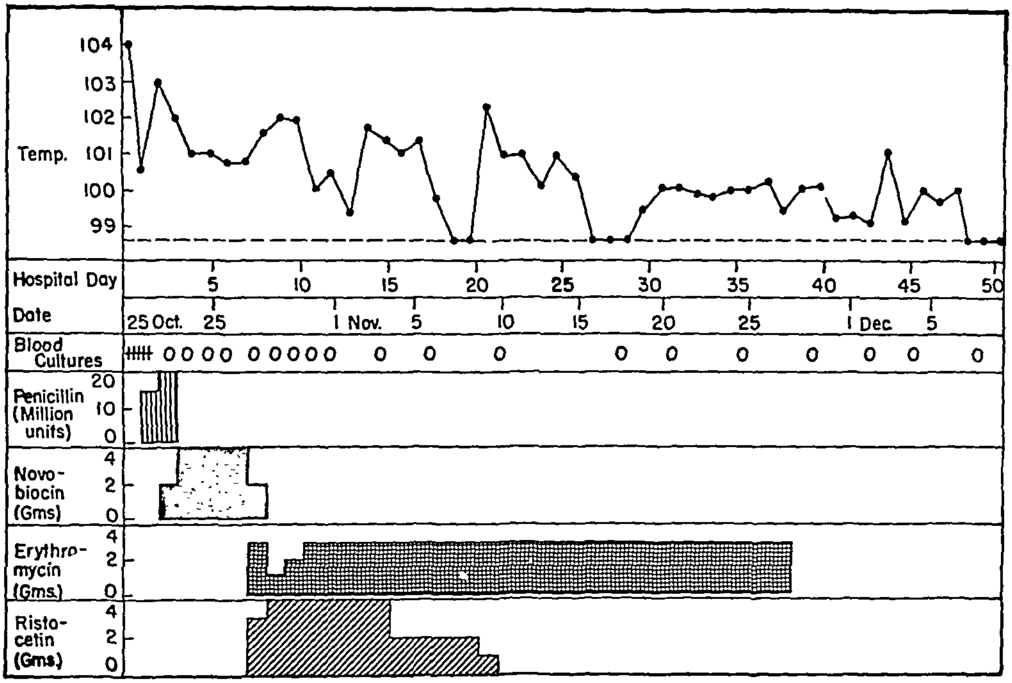

Fig. 3 (case 2).—Temperature curve of patient with staphylococcic endocarditis treated with penicillin, novobiocin, erythromycin, and ristocetin.

A total of 42 Gm. of ristocetin was given to this patient. Serum concentrations of this antibiotic were determined on four occasions, four hours after administration of the drug. Staphylococci previously isolated from this patient, with known sensitivity to ristocetin, were used in determining the serum concentrations. Serial dilutions of the serum were tested to inhibit growth of this organism. The ristocetin serum levels were 793.6 mcg. per cubic centimeter on Oct. 30, 198.4 mcg on Nov. 1, 49.6 mcg. on Nov. 4, and 396.8 mcg. on Nov. 7.

The white blood cell counts are shown in figure 4. On Nov. 11, she received a single injection of 80 units of ACTH gel intramuscularly. She received no medicaments except erythromycin after this. Hemoglobin level and platelet count, determined daily, remained unchanged from normal.

The systolic heart murmur decreased to grade 2 in intensity. After her discharge from the hospital, she was examined on Dec. 20, 1957, and Jan. 15 and Feb. 4, 1958. Fever and symptoms did not return, and she began working regularly as a medical technician on Jan. 15. On this date, the sedimentation rate was 10 mm. per hour and the white blood cell count was 13,320 per cubic millimeter, with 67% neutrophils.

The previous administration of various antibiotics and steroids initially confused the clinical picture, interfering with establishment of the correct diagnosis. Dermatomyositis was considered, but the absence of physical findings and the subsequent clinical course did not support this diagnosis.

The staphylococcic infection in this patient may have originated from various sources, but at least a "hospital organism" seems involved. Prior to her operation, she had been employed as a medical technician in a large general hospital and could have acquired colonization with hospital strains of staphylococci. The abscesses which developed in the antecubital fossa most likely indicate the site and the source of the staphylococcic bacteremia which resulted in the endocarditis. The history of probable rheumatic fever suggests that the infection occurred on a previously diseased heart valve. A changing aortic systolic murmur and the peripheral emboli would further indicate the aortic valve to be the site of the endocarditis.

Novobiocin had not been administered to this patient previously. Sensitivity studies suggested that this antibiotic could be given in effective amounts. The erythematous rash, fever, and nausea and vomiting which occurred after four days forced discontinuance of this antibiotic. Because of the experience in the previous patient with administration of erythromycin alone, therapy with both erythromycin and ristocetin was started simultaneously. The patient was acutely ill at this time and had numerous petechiae. The clinical improvement which followed warranted the continuation of ristocetin therapy despite the appearance of severe phlebitis in the injected veins.

The persistence of fever despite negative blood cultures was quite disturbing. Clinically, the patient improved dramatically, and laboratory tests substantiated this observation. Fever probably resulted from a combination of the leukopenia and severe bilateral thrombophlebitis. After these improved, she became and has remained afebrile.

Comment

The problem of hospital-acquired staphylococcic infections is well recognized, and the necessity for new antibiotic agents in the treatment of these infections is unquestioned. It would also be desirable that such an antibiotic be reserved for use only in the more serious staphylococcic infections. Ristocetin, therefore, seems to be ideal in meeting this need. The necessity for intravenous administration, the occurrence of thrombophlebitis, and the accompanying striking leukopenia should assure the infrequency of its use in treating less serious infections.

Leukopenia and neutropenia have been reported after the use of ristocetin.[4] Eosinophilia occurring before the leukopenia appears has also been described, but, in these two patients, eosinophilia did not appear until the patients were recovering from their leukopenia. It should be noted that the leukopenia occurred in both instances 15 days after starting therapy with this antibiotic and two days after it had been discontinued. Hemoglobin levels and platelet counts remained essentially unchanged from the values noted before steroid or other therapy was instituted.

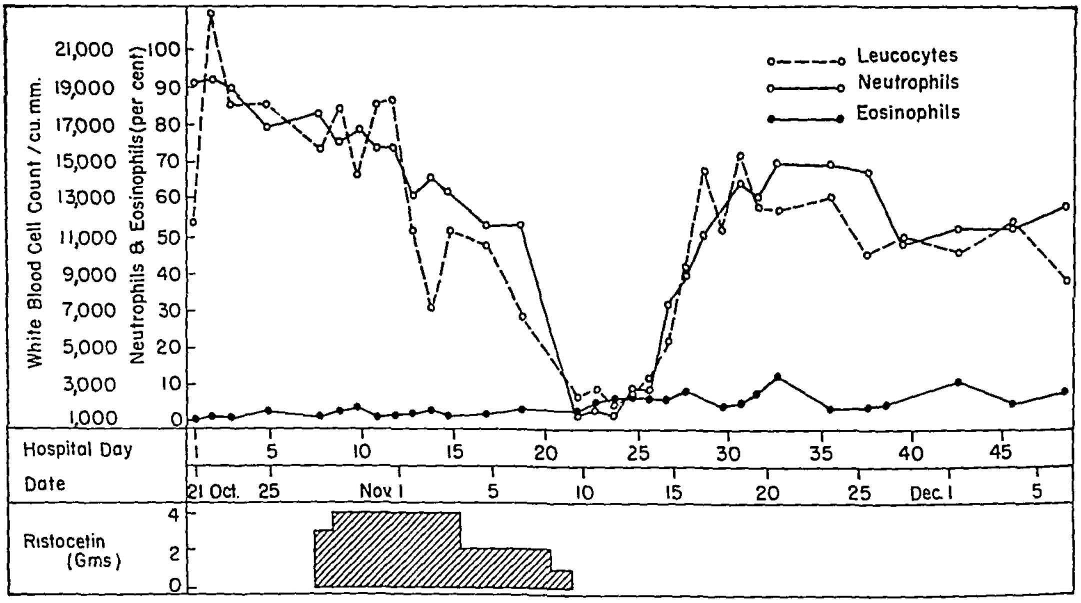

Fig. 4 (case 2).—Effect of ristocetin on leukocyte, neutrophil, and eosinophil counts in patient with stapylococcic endocarditis.

Summary

In two cases of hospital-acquired staphylococcic bacterial endocarditis the patients were treated with ristocetin and erythromycin, with clinical and bacteriological cures. Severe leukopenia and neutropenia occurred in both patients after the use of 44 and 42 Gm., respectively, of ristocetin in 13 days. The hemoglobin levels and platelet counts remained normal. The white blood cell counts gradually returned to normal limits.

Thrombophlebitis also developed in both patients during the intravenous administration of the antibiotic. The thrombophlebitis was severe and was responsible for persistence of fever in one of the patients. Ristocetin is a valuable antibiotic in the treatment of serious hospital-acquired staphylococcic infections.

Kathryn Rodecker, M.A., performed the bacteriological studies.

The ristocetin used in this study was supplied as Spontin by Abbott Laboratories, North Chicago, Ill.

COUNCIL ON INDUSTRIAL HEALTH

SOME MEDICOLEGAL ASPECTS OF OCCUPATIONAL DERMATOSES

This is the fourth in a series of reports prepared by the Committee on Occupational Dermatoses of the Council on Industrial Health, American Medical Association.

B. Dixon Holland, M.D., *Secretary.*

Despite the fact that remarkable strides have been made in preventive medicine and that with few exceptions occupational diseases are preventable, thousands of occupational dermatoses claims are compensated each year. Differentiating industrial skin diseases from clinically similar skin disorders occurring in ordinary life is a major problem in itself. Even more troublesome to the physician are problems arising from the medicolegal aspects of compensation. In all likelihood, these difficulties will continue to grow rather than decline, particularly in view of the increasingly complex number of contact agents being handled in industry. The American Medical Association Committee on Occupational Dermatoses, therefore, considers it timely to review some medicolegal aspects encountered in occupational dermatology. Although most physicians have had to deal with compensation matters, there still remains a great need for educating the profession in this field.

The first workmen's compensation law in the United States was passed in 1908 by the federal government for the benefit of certain civil employees, and in the states in 1911. The early laws afforded no specific coverage for occupational diseases. At the present time, all states compensate for occupational accidents and all but two states provide for total or limited coverage of occupational disease. Eighteen states and Puerto Rico have schedule laws which cover only listed diseases, while the rest of the jurisdictions provide for full coverage.[1] Under full coverage laws industrial dermatitis is subject to the same compensation provisions as other occupational diseases. However, laws with schedule coverage of occupational diseases tend to limit the types of industrial skin diseases considered compensable or define the agents which must produce the disease.

The object of workmen's compensation is to assure payment to the worker for wages lost and certain related medical costs because of injury or illness incurred on the job, regardless of who is at fault, and to rehabilitate the patient as well as possible. The compensation laws vary considerably from state to state in scope, coverage, and benefits. Likewise, there is a lack of uniformity in the interpretation and application of such laws. This lack of uniformity creates many problems in the litigation of an injury and illness including dermatitis incurred from work.

Among the many legal definitions for an occupational disease is: "An occupational disease is one peculiar to the occupation in which the employee was engaged and due to causes in excess of ordinary hazards of employment as such."[2] Sappington[3] has defined an occupational disease as "one which

---

The members of the Committee on Occupational Dermatoses are Drs. Donald J. Birmingham (Chairman), Cincinnati; Leonard Weber (Secretary), Chicago; Frank C. Combes, New York; A. Fletcher Hall, Santa Monica, Calif.; James W. Jordan, Buffalo; George Morris, Boston; and Ray O. Noojin, Birmingham, Ala.

occurs with characteristic frequency and regularity in occupations where there is a specific hazard as the cause which operates to produce effects in the human body recognized clinically by the medical profession as pathologic changes and effects produced by the specific occupational hazard involved."

An occupational dermatitis has been defined as an inflammatory condition of the skin incidental to one's occupation. Broadly, this definition would include the housewife's dermatitis, the gardener's plant poisoning of the skin, and the architect's dermatitis from his teakwood ruler. Actually, an occupational dermatosis is any abnormality or pathological condition of the skin due to occupation. These definitions seem fairly simple, but the industrial physician, even the dermatologist, may have difficulty in determining whether or not the cause for a given cutaneous eruption is of industrial nature.[4]

It is important that the practicing physician familiarize himself with the compensation law in his own state as well as with the peculiarities associated with particular compensation problems in occupational dermatoses. For these reasons, we have deliberately chosen to elaborate on certain topics of current interest in order to emphasize their relationship to legal aspects of an occupational skin disease.

Sensitivity

An interesting problem is presented by the employee who, by reason of his occupation, has developed a specific sensitivity to a certain substance which makes him unfit to continue his trade, although his condition is not such as to disable him physically. In one case,[5] the claimant had been disabled by a dermatitis from September, 1932, until April 12, 1933, when he returned to his occupation. On June 14, 1933, he was told that he could work no longer on account of his sensitivity. He then was awarded total disability by the industrial accident board. The court decided that, although the original eruption had disappeared, the employee's skin had never returned to normal; testimony in the record was sufficient to justify a finding of "disability as to the particular employment, but not as to employment in general. It was the duty of the employee to try to get other work."

Claims for permanent disability from sensitization are now plaguing the courts. One such set of claims due to sensitization from chrome compounds among railroad workers employed in the maintenance of diesel engines is of interest at the present time.

Another case[6] is reported in which a claimant sought a compensation award for permanent disability resulting from his sensitivity to cinnamon. From a denial of such award the claimant appealed to the U. S. District Court of Appeals, first district, division 1, California. He had worked as a baker since 1922, handling cinnamon without harmful results. In November, 1948, he was employed as a pastry baker. The following February a rash developed on his hands, becoming so acute that he quit work on March 10, 1949. The commission determined that he had contracted a disabling dermatitis which was caused by sensitivity to cinnamon and gave him temporary total compensation.

The condition disappeared in April, and he went to work as a baker for another employer. After three days the condition reappeared, and a few days later he was again forced to quit work. After a short period of rest the condition disappeared. Twice later he went to work for other employers and after extremely short periods of employment again broke out with a dermatitis due to his sensitivity to contact with cinnamon. Each time he received total compensation, each time his dermatitis cleared on cessation of contact with cinnamon, and reappeared on subsequent exposure. He then filed his petition for a permanent disability rating. At the hearing before the commissioner the claimant submitted the reports of five physicians, one of whom was his personal physician. All agreed substantially that at that time he was sensitive to cinnamon and that his exposure to it produced a dermatitis. None of the physicians other than his own reported on the permanency of this sensitivity. The only medical evidence in the record is the following report of his personal physician: "Because this skin test is still positive to cinnamon, the patient would still be unable to work as a baker without having a recurrence of his skin eruption as long as he contacts cinnamon. This skin sensitivity to cinnamon will probably remain for an indefinite period of time, but it is impossible to know how long such a sensitivity will remain."

On the basis of this evidence the claimant then contended on appeal that the commissioner erred in finding that the claimant suffered no permanent disability. After pointing out that whether the injury was permanent at a particular time was purely a question of fact and that the burden of proof was on the claimant to show that his sensitivity to cinnamon was permanent, the court of appeals said that it was a fact that on four different occasions since 1949, when exposed to cinnamon, dermatitis developed, and all the physicians agreed that the claimant is now sensitive to cinnamon, and exposure to it at present will result in dermatitis. These facts alone, continued the court, do not establish that such condition will continue for the balance of his life or meet the test of permanent disability. A disability is generally regarded as permanent when further change, for better or worse, is not to be reasonably anticipated under usual medical standards. The court of appeals affirmed the denial of an award by the compensation commissioner.

In another case,[7] the workman, about 41 years of age, was employed from 1935 to August, 1940, in the gasoline and petroleum products bulk station of the defendant corporation unloading gasoline from tank cars and loading gasoline into trucks. Sometime after entering his employment he developed a dermatitis which did not result in disability. In the summer of 1939 an eruption developed on his hands, arms, and face; it was diagnosed by a dermatologist as an allergic dermatitis due to contact with gasoline and he was treated at intervals for about two months. On April 27, 1940, he again developed an eruption on his hands, and was again treated until June 22, 1940, when the eruption was pronounced as cured. He continued at his regular work until Aug. 31, 1940, when the employment was terminated by the employer because the workman "was allergic to gasoline poison." He instituted proceedings under the workman's occupational disease act of Indiana for compensation, "alleging that in the performance of the duties of his employment . . . he was exposed to an occupational disease and that he is afflicted therefrom with 'gasoline poisoning-dermatitis-due to gasoline poisoning.'" The industrial board found that the workman contracted an occupational disease by reason of his employment, that he was totally disabled from that disease on Aug. 31, 1940, the date his employment was terminated by the employer, and that he was totally disabled from that date until the hearing before the board, some four months later. An award of compensation was made accordingly in his favor, and the employer appealed to the appellate court of Indiana. Applying the facts in the case, the court concluded that the finding and award of the industrial board was erroneous. The workman was not disabled on the 31st day of August, 1940. When his employment was terminated on the latter date he suffered no disability that caused any loss of time or wages or that would entitle him to be designated as disabled under the act. "It is possible that the allergy still exists, but a fair interpretation of the act leads us to the conclusion that a mere allergic condition from which some affliction might develop was not contemplated in the act." The award in favor of the workman was accordingly reversed.

In another case [8] occupational dermatitis was considered an accident. A workman in New Mexico instituted suit under the workmen's compensation act against his employer and the employer's insurer for an injury alleged to have been accidental and to have arisen out of and in the course of his employment as a printer. The trial courts found that in the course of his employment it was necessary that he cleanse his hands frequently with a soap furnished by the employer. The court found that the use of the soap would not have caused injury to the workman except for his allergy and that the resulting injuries constituted an unlooked for mishap which was neither expected nor designed and which was accidentally caused. Accordingly compensation was awarded the workman, and the employer and the insurer appealed to the Supreme Court of New Mexico. The employer and insurer denied that the disability suffered by the workman was accidental because, so they contended, the so-called injury was not related to any specific time or event, a necessary fact to be found, so they asserted, to support a judgment in his favor. The New Mexico statutes, answered the Supreme Court, not only do not define the word accident but do not undertake to limit its meaning to "sudden" injuries as do those of a number of the states, nor is its meaning limited by any time test. Accidental injuries, continued the court, are usually sudden happenings; and the time, event, and circumstances can be definitely determined, but there are exceptional cases in which injuries are unquestionably accidental, although the precise time of their beginning is uncertain, such as those caused by breathing dust or gases, frost bite, slow poisoning, or a series of slight injuries culminating in a serious one. An injury may be gradual and progressive, and not immediately discoverable, yet certainly and definitely progress to discovery and then to compensable injury. Such was the injury to the workman in this case. The time did arrive when his injuries totally disabled him so he could not work, and at that time he became entitled to compensation for total disability. The washing of the workman's hands was a necessary part of the labor for which he was employed. His injury, therefore, arose out of and was suffered in the course of his employment, and, if accidental, it was compensable. It comes under the classification: an injury that was the unintended result of an intentional act; received while performing his labor under the usual and ordinary conditions of his employment. The plant soap was a poison to the workman, and his injury was compensable. The judgment of the trial court in favor of the workman was accordingly affirmed.

New Injury or Recurrence

In Massachusetts the board has certain fixed ideas regarding medical aspects of occupational dermatoses. Conspicuous among these are the words "new injuries" and "recurrences." If a man suffers a disability from an injury caused by an industrial dermatitis, he is entitled to compensation. If this dermatitis is relieved so that there are no clinical evidences of it remaining, and the man returns to work, any subsequent outbreak due to further exposure is a new injury and the liability should be assumed by the insurer of the last concern by whom he was employed. If, however, the worker returned to work while the original dermatitis was still present and as a result of this work he has an acute exacerbation of his previous dermatitis, then the company who insured the original employer is liable for compensation for disability resulting from this later renewed activity of the occupational dermatitis. It is on these apparent primary facts that many hearings are held at the industrial accident board and as many as three or more insurers may be involved in one case.

Appeals must come to the superior or supreme courts on questions of law and not on questions of fact. Legal representatives of employers and employees go to considerable expense and trouble in an effort to establish definite rules of law for general guidance in the handling of workmen's compensation cases. As a result of decisions made the industrial accident board has tried to adhere to the rule that once an employee is relieved, that is, shows no clinical evidence of his dermatitis and returns to work, any subsequent outbreak is a new injury for which the liability rests on the insurer of the employer at the time of the second attack, whether or not he is the original insurer.[9]

There were, however, three decrees of the State Supreme Court of Massachusetts concerning cases in which the employees, after having received compensation from the insurers of their employers, went to work for other employers where they were subjected to irritants and became disabled again, and where the industrial accident board had held the original insurers liable for the compensation. The Supreme Court reversed these decisions and said that in each case there was no evidence that the subsequent attacks of dermatitis were due to the original exposure rather than the later contact with irritants, the latter being an independent intervening cause which broke the chain of causation between what happened originally and the disability in question.[10] A fourth case contained evidence of a conflicting nature; upon practically every point again the board held the original insurer liable. This time the court sustained the board and decided that the evidence warranted a finding that the original dermatitis never cleared up and that, since there was no evidence to show that the further exposures affected the original condition, the rule laid in the previous cases was not applicable.[11]

Inasmuch as the annual workmen's compensation insurance premiums of an employer are influenced by the amount of money paid as benefits under the act, there is an incentive for concerns to throw back the liability onto a previous insurer. As opinions of the physicians and resulting decisions must depend almost entirely on the statements of the claimant and others, it is here that we often listen to testimony of apparently prejudiced witnesses. When we ask a private patient, not seeking compensation or redress for his dermatitis or eczema, the duration of his eruption he may unhesitatingly say "years." However, careful analysis reveals that it may be periodic or may have cleared at various times only to reappear days, weeks, or months later. So the employee seeking compensation may truthfully state his eruption has been present since the original onset. He may believe he has been poisoned, and it is in his system; hence, the value of a careful history, and also the supreme necessity of treating a patient until every vestige of the dermatitis has disappeared for a reasonable period. It is also important because, if a patient's skin is thoroughly healed, he is more apt to remain well when he returns to work. If a man's former work involved contact with sensitizers which led to a dermatitis, then he should be advised not to return to that work. If he has been injured by a recognized primary irritant he should avoid that substance or handle it with proper respect, so that he can frequently return to his former occupation with impunity.

There would be fewer disputed cases before the industrial accident board if the courts accepted the fact that the compensation act provides for disability only. What holds for a strained back should also hold for an occupational dermatitis, as was demonstrated in Borstel's case, 307 Mass. 24, where the Supreme Court ruled that, despite the fact that the man had previous injury to his back, the final act which produced disability was his work at his last place of occupation, and therefore found that the last insurer should assume liability. However, the chief objection to this is that it would be absolutely necessary entirely to relieve a patient from his occupational dermatitis before he resumed any type of work, and would result in employers refusing to accept or hire an individual suffering from any type of rash. This would, of course, prevent numerous workers from resuming work, for there is no question that a slight eruption does not always disable an individual from doing work that does not involve contact with irritants. Therefore the board continues to rule on the particular facts in each case individually, and the State Supreme Court treats each case on its own merits. There is no uniformity —perhaps not even any consistency—in the decided cases.

Aggravation

Aggravation of preexisting disease through an occupational injury should be compensated only for the period of time during which the aggravation is actually and entirely caused by the injury. One should try to determine the disability due to the compensable injury and that which is due to the preexisting disease. If the patient stops work, and if the effect of the injury on the preexisting dermatosis has been eliminated, and if treatment has resulted in relief of the superimposed occupational dermatitis, compensation is no longer justified. The problem becomes still more involved if the preexisting disease, such as psoriasis, is a progressive one. The difficulty then is to decide when the preexisting disease has reached the stage which it would have reached without the influence of an injury. During this period the disability is also progressive. There may be no justification for further compensation because the role of the occupational dermatitis as a contributing factor has ceased—however, most of these cases are awarded compensation for the entire disability, primarily because of conflicting testimony as to when, if at all, the aggravation has ceased.

Apparently no hard-and-fast rule or formula can be applied to the word aggravation. The exact conditions of each individual case produce a decision peculiar to that case. From a large number of such cases, however, certain concepts with wide border lines may be derived. If a workman has had psoriasis for many years prior to engaging in an occupation, during the course of which his psoriasis has become worse, so severe that it involves his hands with a result that he has been unable to continue at that particular occupation, which may or may not be an aggravating factor, he usually sues for compensation. He claims that the disability which eventuated was an industrial injury.

In such a case in Massachusetts psoriasis of the palms developed in an edge setter after he had been working for 10 years. In the performance of his work, the edge setter painted the edges of the soles of shoes with a blacking compound and then pressed the edges against an electrically heated, vibrating iron. About six months after the onset of the eruption on the palms, psoriatic areas also developed on the plantar surfaces. The edge setter was examined for the insurer, and an opinion was expressed that the condition was psoriasis not of occupational origin. The decision of the Massachusetts Industrial Accident Board on his claim for compensation was that "the employee . . . sustained an injury that arose out of and in the course of his employment" and that "as a result of this injury he was totally disabled for work" for 13 weeks. Fourteen years later, this same worker was again referred for examination and opinion, this time by a different insurer for a different employer. Although there had been some variations in the intensity of the eruption, it had never been completely clear during this interval of time. The edge setter worked for the first employer for about two years after the first industrial claim. Thereafter, he worked for six different employers, doing essentially the same type of work. The Board describes the interval of approximately 13 years in these words: "The employee has persistently pursued the same type of employment in the shoe industry, namely, edge trimming and edge setting, and notwithstanding that he has suffered intermittent repeated exacerbations and remissions of cracked and swollen hands, principally on their palmar surfaces, with rash, scaling, and redness, when the condition was acute and severe. . . ."

A dermatologist called as a witness by the employee at the last hearing testified that "the work as an edge trimmer and edge setter aggravated the basic condition of psoriasis." One impartial dermatologist expressed the opinion to the Board that the employee "has an eruption which is psoriasis," and that this is "a constitutional disease in which trauma 'can be' the 'initiating' cause"; he also believed that "continued work handling stains, shoes, and other ingredients 'could' aggravate his (the edge setter's) psoriasis." Another impartial dermatologist consulted by the Board expressed the opinion that "the condition which the employee suffers is psoriasis and is in no way causally related to his employment at any time." The full Board, in their findings after review, made the following statement:

> We prefer to follow the opinion . . . that the condition which the employee has suffered is one of psoriasis, a nonindustrial disease, that such disease has not been aggravated by any of the employments against which claim is made on the record. . . . We find that the employee has not sustained the burden of proving that he has received a personal injury arising out of and in the course of his employment in the service of any of the employers against whom claim is made subsequent to the 1936 episode. We find further that the employee's incapacity beginning on September 9, 1949 is not causally related to his 1936 injury.

Here apparently are diametrically contradictory opinions by the same Board for the same employee, suffering from the same and continuing condition of psoriasis while engaged in the same industry. The two hearings differ from each other in that different employers are involved; they also differ in a matter of jurisdiction regarding one of the employers because of location in another state.

Appel[12] states that an analysis of a large number of industrial dermatitis cases in which the factor of aggravation played an important part permitted all the cases to fall into one of the following five categories: industrial dermatitis (1) aggravated by a supervening nonindustrial condition; (2) aggravated by a supervening other industrial condition arising out of and in the course of employment for the same employer; (3) aggravated by a supervening other industrial condition arising out of and in the course of employment for a different employer; (4) aggravated by a preexisting nonindustrial condition; (5) itself aggravating a preexisting nonindustrial condition.

If a patient is accepted as being disabled as a result of aggravation of his nonindustrial dermatitis, then the physician must try to discriminate between the natural development of the nonoccupational eruption and the disturbances caused by the injury received at work and should be able to determine when the results of the aggravation have ceased and only the preexisting disease remains. If the patient had suffered from a clearly defined systemic cutaneous disease, such as psoriasis or syphilis, this decision is fairly easy. For example, if a man suffers an injury to his leg and then develops a localized patch of psoriasis, he should receive treatment only until this patch is relieved. The same is true regarding a gumma resulting from injury. However, such an injury as in the case of the loss of the sight of both eyes in a patient with syphilis might result in total permanent disability.

The latter was shown in the case of Nicotra vs. Bigelow, Sanford Carpet Co. (Conn., 189 A.603).[13] The claimant, while at work cleaning the inside of a metal tank with an electric brush, complained to a fellow worker that something had got into his left eye. Shortly afterward the claimant reported to the plant surgeon, who found some pieces of foreign matter in the eye, which he apparently removed. The claimant, however, continued to insist that there was still something in his eye, and during the next several months he received treatment from various physicians but obtained no relief. Eventually be became totally blind in his left eye. Vision in his right was reduced to less than one-tenth of normal vision and the condition could not be corrected by lenses. During the course of treatment for his eye condition it was discovered that the claimant had syphilis and he underewent treatment for that disease. In a proceeding under the workman's compensation act of Connecticut, the commissioner awarded the claimant compensation and the employer appealed to the superior court, which remanded the case to the commissioner for the taking of further evidence. The claimant thereupon appealed to the Supreme Court of Errors of Connecticut.

The commissioner concluded that an injury which the claimant received to his left eye precipitated an optic neuritis in that eye and that atrophy of the optic nerve developed, resulting in total blindness in that eye; that sympathetically the right eye was affected by the injury to the left, so that the net results of the injury was that the claimant was industrially blind in both eyes. The employer contended that it was error for the commissioner to receive the statement in evidence. The contention, the court said, overlooks the nature of the hearing before the commissioner. The law provides that the commissioner shall not be bound by the ordinary common law or statutory rules of evidence or procedure and is therefore permitted great latitude in the admission of evidence. The employer further contended that an award of compensation to the claimant was not permissible because the workmen's compensation act provides that in case of an accidental injury a disability or death due to the acceleration or aggravation of syphilis does not constitute a compensable injury. Under this provision, the court said, where the effect of the injury is to accelerate or aggravate the constitutional disease, no recovery can be had. In the present case the ultimate conclusion of the commissioner was that the injury which the claimant received because of his condition affected the optic nerve in such a manner as to result in loss of sight of both eyes. As the record supported this conclusion, the court said, the disability was compensable. The case was remanded to the superior court, with directions to enter judgment for the claimant.

Disfigurement

Another problem coming before the industrial accident boards is disfigurement. Previously it was considered not compensable. A case[14] was reported in which the claimant's face was badly scarred by acid, resulting in considerable disfigurement. He was not otherwise injured and instituted proceedings under the workmen's compensation act of New Jersey. The question as to whether or not disfigurement constituted a compensable disability eventually was presented to the Supreme Court of New Jersey. A reading of the several sections of the workmen's compensation act, said the court, clearly indicates a legislative purpose to provide compensation for disability which disqualifies an employee from doing work in whole or in part. In De Zeng Standard Co. v. Pressey, 86 N. J. Law 469, 92 A. 278 (affirmed in 96A.1102) the court said: "The disability intended thereby (the act) is a disability due to loss of a member, or part of a member, or of a function, rather than to mere loss of earning power." In that case it was claimed that if there was injury but no loss of actual wages there was no loss of earning power, and that this precluded an award. The court, however, refused to take this view, declaring that it was disability alone that counted, whether loss of physical parts or loss of function. In the present case the court said that the disfigurement and scars on the claimant's face may well deter employment and thereby lessen his earning power, but they in no wise impair his ability to work. If disfigurement, standing alone, is to be made the basis of compensation, it must be done by the legislature and not by an extension of the act by judicial construction. If and when such legislation shall be deemed desirable, the court said, the legislature can determine what types of disfigurement, marks, and scars, and on what portion of the face, head, or body, shall be considered, and within what limits and bounds awards of compensation shall be made.

However, Bear[15] later cites a case tried before the Massachusetts Industrial Accident Board, L. Hendricks v. Chesterfield Laundry Service Company. This employee was a 31-year-old woman who was operating a laundry pressing machine. A part of the machine weighing about 50 lb. shut down on her right forearm, burning her. She managed to free herself and then fainted. After treatment, a granulating surface was obtained. The large open surface was filled in with skin grafts. This graft took fairly well, except that where it crossed the wrist joint there was some stiffness and cracking due to the motion of the joint at that point. The important feature of the case, however, was that the patient was left with an extensive keloid formation, which disfigured her arm. The employee testified at the hearing that she was sent from an employment agency to two different families to do housework. The prospective employers kept looking at her arm, and the agency was notified after each interview that she had not been hired because the scar was considered obnoxious. The commissioner found that this constituted a disability and awarded compensation, which the insurer paid without appeal to the courts.

Patch Tests

Testimony concerning the value of patch tests at hearings before industrial accident commissions may be a great tribulation to a conscientious physician. He must perform and interpret the test himself; otherwise, it is hearsay evidence and therefore irrelevant. It is difficult for the physician to explain a negative reaction, when he is certain that the patch test did not simulate the conditions under which the employee's skin was exposed to the irritant. On the other hand he cannot explain an apparently positive reaction appearing at the site of the test, when it could be merely another patch of a spreading eruption that involved the test site. Lawyers and commissioners have difficulty understanding false-positive, false-negative, and delayed reactions to patch tests.

Among the legal questions which occasionally confront the dermatologist who investigates cases of industrial disease are those which arise when a patch test is performed that causes a severe and possibly disabling dermatitis. An opinion was requested from the Massachusetts Industrial Accident Board[16] regarding the liability of the physician to the claimant, the liability of the insurer to the claimant, and the rights of the claimant over the physician and the insurer. The Board's reply was intended to furnish helpful information and not to set forth the law.

On June 14, 1940, Mrs. F. at her employer's request removed a ladder from under considerable brush. In so doing she was showered with a pollen-like substance, which covered her head, face, neck, and arms. That night her face grew red and itchy and later burned. The next day it was erupted and swollen. She received medical treatment and was confined to the house for seven weeks. Even after that time itching and burning continued, and red patches appeared on her face whenever it was exposed to heat. When first examined on Aug. 20th, her skin was normal except for slight erythema of the face. She was accompanied by an inspector of the Massachusetts Department of Industrial Accidents; he brought with him specimens of four plants like those with which the patient came in contact and requested patch tests. These tests were performed on the flexor aspect of the left forearm with a minute piece of each plant. Within a few minutes the patient complained of itching, and an area of redness was observed surrounding the test piece of a plant called by the patient a Chinese plant. Despite removal of the substance and cleansing with soap and water and alcohol, the redness continued to spread and covered an area 4 in. (10 cm.) square. The other patch tests were negative. On Aug. 21st the patient returned with a dermatitis of the left forearm.

The results in the above case aroused interest anew in certain legal questions to which such results give rise. Is one justified in performing a patch test that may cause an aggravation or, if the patient is well, a new and disabling dermatitis? Is the one who requests the test or the one who performs it liable for such disability? Should the consent of the insurer to the test be secured as well as that of the patient? Was one justified in undertaking treatment of the patient during the illness that ensued? Who should pay for this treatment, the state or the insurer? If the patient had been disabled by the dermatitis caused by the patch test, would she have been entitled to further compensation?

To a letter presenting these questions, the Board replied that since in performing the patch test the physician was acting under appointment by an administering board with legislative permission so to appoint and since it was a procedure generally endorsed by the medical profession, he should probably be immune from suit by the insurer and certainly immune from suit by the employee (as held by the Mass. Supreme Court in the case of Vatalero vs. Thomas, 262 Mass. 383). The Board pointed out that in view of its having appointed him, his position was neither that of physician to the employee nor physician to the insurer. As to the employee's right to further compensation for an aggravation and extension of the original dermatitis, the Board cited the fundamental principle that the insurer is liable for all the consequences which flow "as a rational result" from the original injury. Among these consequences it included any conditions resulting from examination and treatment by any physician, whether impartial or employed by the employee or insurer, provided that these were properly conducted and were recognized procedures. In connection with the Board's reply, a private legal opinion was solicited while the patient was still under treatment. This opinion was that there is no liability on the part of a dermatologist unless he is negligent in treatment and that he is therefore under no obligation to obtain permission from any one to perform a patch test. In the case of a subsequent eruption, it was held, the insurer would be liable for disability, if any, since examination by an impartial physician is provided for under the Workmen's Compensation Act.

Cost

A dermatitis case can be quite expensive. The following case, while somewhat unusual, illustrates this point and also directs attention to one of the principal causes of prolonged dermatitis—overtreatment. On Oct. 18, 1949, a man 50 years of age was referred by an insurance carrier for examination of a dermatitis resulting from contact with cutting oils used in his work as a metal worker. The eruption started the previous April on the anterior aspect of the thighs, later involving the wrists and forearms. In December, 1949, he was referred back for therapy, for his eruption had become generalized in spite of x-ray therapy, injections of penicillin, and various other medication. He was hospitalized with marked improvement, although the pruritus persisted. Contrary to advice he continued using various home remedies. In October, 1951, at the request of the insurer he was seen at a suburban hospital where his own doctor was treating him. A month later a local physician referred him to a large teaching hospital. Here he was placed under the care of an internist who was specializing in steroid therapy, which was then both experimental and very expensive. Cortisone therapy was started on Dec. 2, 1950, and he remained on steroid therapy under the care of this internist until a short time before his death on Nov. 16, 1954. At first he made excellent progress as regards his skin, but he soon showed untoward reactions each time the drug dosage was lowered or withdrawn. He had a total of 14 hospital admissions. The total medical cost in this case [17] was reported to be $34,014.25. The compensation paid over a period of five years was $8,758.57. His widow 54 years of age is now being paid $15 a week for life, so that another $15,600 expenditure is expected, making a total of $58,000.

Rehabilitation

For an employee, disability creates a problem which will vary in degree according to the occupational or nonoccupational character of the ailment, the age of the worker, the length of time in the particular trade, and the accumulated seniority within the company. If he or she is a beginner in the employment and if the trouble is ruled as work-associated, the illness is covered by compensation. In such a case transfer to another department or separation from the job will not cause loss of the higher wage scales gained after long experience.[18] However, when a man has learned a highly specialized trade, such as engraving, and he becomes disabled because of skin irritants, he is of no value to his employer or to others in any job involving contact with skin irritants. Although he is compensated for this episode, he still faces the penalty of a lowered income. This results from the necessity of a plant transfer to another job in which he has no trained skill, or severance from the position in which he has developed efficiency and seniority. Lost time which is not covered by any type of benefits can be catastrophic to him and his dependents.

The trained artisan will frequently, and with some justice, decide that his disability, no matter how slight, has a certain monetary value. Workers may demand a high price for a dermatitis of one finger which does not disable them from ordinary work, but may eliminate them from their trade. They are apt to prolong this dermatitis until they are given a lump sum settlement, with the result that the patient is not so much interested in his physician's effort to restore him to work as he is in his financial settlement. On the other hand, occasional attempts may be made to deny a worker's just claim or to settle a claim more cheaply in a lump sum which terminates an employer's liability for compensation.

Lack of rehabilitation services and inadequate medical care may result in prolonged disability and unnecessary loss of gainful employment, as well as an occasional neurotic, permanent invalid. After the acute disabling symptoms of occupational dermatitis are relieved, work away from contact with irritants should be found. Rehabilitation through vocational training may be necessary.

This aspect of disability is relatively new as compared to the problems of prevention and compensation of occupational dermatoses. There is no uncertainty about its importance, because rehabilitation provides a means of reestablishing the vocational and economic usefulness of the skilled worker who, by virtue of his cutaneous susceptibility, must change type of work. Real recognition for the need of rehabilitating the disabled workman is evident, for at this time about 23 states have certain provisions dealing with rehabilitation. When physicians are confronted with the need for rehabilitation of a patient with a dermatosis, they should confer with the employer and the insurance company or consult their state departments of health, or workmen's compensation office, or departments of labor to ascertain whether a rehabilitation activity is available within the state.

Conclusions

It is the duty of all physicians to care for the sick. Workers suffering from occupational dermatoses are sick and need proper care. Some specialists have been reluctant to take compensation cases. They claim they are ignorant of the law, lack medicolegal training, fear legal interrogation, and believe the fees are so low that expenditure of their time is not properly compensated. If a physician undertakes the care of the patient, it is his duty to appear and testify. Knowledge of the workings of the compensation act is desirable. The physician should realize that he is not beholden to anyone. The position of the dermatologist is that of a physician trained in the diagnosis and treatment of cutaneous disturbances. He has sufficient knowledge to recognize whether or not it is systemic in origin, or due to extrinsic factors. If due to the latter, and a careful history reveals the probability of occupational factors, an honest statement of the facts can withstand any direct or cross-examination to destroy his opinion. If a careful history narrows the field of probable causative factors necessitating the aid of the patch test, the dermatologist should not hesitate to employ such diagnostic aids.

His testimony should be independent of his lawyer, the plaintiff, or the defendant; in court he is not an agent of either, but subject only to the ethics of his profession. He should not be partial or prejudiced to either side. Antagonism by a lawyer for either side is quickly recognized (and usually remedied by the presiding officer) and often is a deciding factor in the decision. The physician should be able to recognize the extent of disability and the prospect of the worker's recovery. Proper cooperation between the dermatologist, the employee, the employer, and the compensation administrator will help to reduce the number of controversial cases. The intent of the compensation act is just and humane and is entitled to the cooperation of all concerned.

The Committee wishes to express thanks to Mr. Joseph Bear for his review of the legal questions involved in this paper. The Committee also wishes to acknowledge the contribution of Dr. John G. Downing, former Chairman, in the preparation of this paper.

COMMITTEE ON MEDICOLEGAL PROBLEMS

INTERPRETATION OF TESTS FOR INTOXICATION

Ralph F. Turner, M.S., East Lansing, Mich., Herman A. Heise, M.D., Milwaukee
and
Clarence W. Muehlberger, Ph.D., Lansing, Mich.

This report is chapter 6 from a manual, being prepared by the Committee on Medicolegal Problems, dealing with medical and legal procedures involved in the use of chemical tests for intoxication.

Popular beliefs regarding the effects of alcohol do not agree with the scientifically conducted observations. We have all heard of the mythical individual who "smells the cork" and becomes dead drunk, while another is cold sober after downing a "fifth." Actually the startling fact is that alcohol affects human beings in a surprisingly uniform manner when we measure, not how much the person drinks, but how much he accumulates in his body fluids. This uniformity is demonstrated by observing that the threshold for measurable effects of alcohol usually occurs at a blood alcohol level of about 0.02 to 0.03%, indicating the accumulation of 0.4 oz. (12 cc.) to 0.6 oz. (18 cc.) of pure alcohol in a 150-lb. (68-kg.) person. The fatal dose also is no respecter of persons. When a person accumulates enough alcohol to have a blood level of 0.6%, his most primitive nerve functions are interfered with and he dies.

Evaluation of Tolerance

It is true that habituation to alcohol alters these figures slightly, but the importance of tolerance has been greatly overrated. While the tolerant person may be able to drink more than the novice, the two will be about equally intoxicated when they accumulate the same amount of alcohol. The tolerant individual may eliminate his alcohol faster and absorb it slower. It is also possible that what we regard as tolerance may actually be an ability, acquired by practice, of hiding some of the symptoms of intoxication. For example, the often intoxicated individual may have learned to talk softly, to enunciate clearly, and to drive with exasperating slowness. It should therefore be understood that the chemical test for alcohol is just, since it measures not how much the person drank but what he accumulated, and it is the accumulated alcohol that causes intoxication.

If the above statements are true, why then are we confronted with apparent contradictions? How can we explain that, of two persons of about the same age, height, and weight, both charged with driving while intoxicated, both having 0.15% alcohol in their blood, one is polite, cooperative, and well oriented while the other is profane and combative? The explanation for this apparent paradox has been found by the testing of hundreds of individuals before and after taking alcohol. It can then be shown that there is a great natural difference in persons. The intelligent person accustomed to the successful handling of himself in difficult situations will appear to be less affected by alcohol than the scatterbrained person whose blood contains the same percentage. The experiments indicate that the two persons, though reacting differently, are about equally removed from their own normal behavior patterns.

It has therefore been suggested that the superior person be judged by a more lenient standard than that imposed on his less fortunate brother. We feel, however, that this attitude is not reasonable or feasible, since driving even without alcohol is such a hazardous occupation that any reduction in driving ability caused by alcohol should not be countenanced.

Effect of Suprarenals

Another interesting observation is that a person may have been obviously intoxicated, but when he is confronted by the police or being examined by a doctor suddenly appears to be sober. What has happened is that the realization of his predicament has caused his suprarenal glands to secrete large quantities of epinephrine, which temporarily counteract the effects of alcohol but not the percentage in his body fluids. When this person believes that the emergency has passed, he again relapses to his observable state of intoxication. This temporary, apparent sobriety can be compared to what happens to the sleepy individual whose house catches fire. As soon as he realizes what is happening he is wide awake.

When we consider the variety of symptoms, or even the temporary absence of symptoms associated with alcoholic intoxication, it is fortunate that we have available one constant finding which enables us to evaluate properly the role of alcohol as a factor in abnormal behavior. This was dramatically demonstrated by Halporn [1] when he was able to prophesy with surprising accuracy the percentage of alcohol which would be found in the urine of persons whom he had examined. His very worst estimate was 0.30% in a person whose actual percentage was only 0.18. Later on it was discovered that this person had a fractured skull, indicating that the chemical test was an even better diagnostic tool than the physical examination alone.

What Is Intoxication?

In order to interpret the results of chemical tests for alcoholic intoxication, it is obvious that we must define intoxication. This condition has been considered to be present according to some authors only when there has been obvious mental confusion and/or muscular incoordination, while others have considered that a person is under the influence of alcohol as soon as only slight measurable neurological deterioration can be demonstrated. The same person simultaneously examined by two doctors may be considered culpable by one and innocent by the other, depending on the doctor's criteria for intoxication.

It is obvious, then, that all arguments are fruitless unless we agree as to what is meant by "under the influence." We are in favor of any definition which adequately describes this condition and which can be used to convict the guilty and free the innocent. The same definition should apply in all states and preferably in all countries. At the present time we have many definitions of intoxication. To be guilty in California the individual must be so affected that he is unable to operate his vehicle in the manner of an "ordinarily prudent and cautious person in full possession of his faculties." Dr. Henry Newman correctly interpreted this to mean that a person should not be penalized unless the alcohol had lowered his driving ability below that of the poorest licensed driver on the road. According to this definition it is extremely difficult to prove intoxication. The California law exonerates the superior individual who in spite of some loss of his driving ability due to alcohol is still a better driver than most ordinary drivers.

On the other hand this superior Californian would not fare as well if scrutinized according to the laws of Arizona. Because of the difficulties of proving "under the influence" of alcohol, the National Safety Council and the American Medical Association have urged the adoption of the following definition of the Supreme Court of Arizona:

> The expression "under the influence of intoxicating liquor" covers not only all the well known and easily recognized conditions and degrees of intoxication but any abnormal mental and physical condition which is the result of indulging in any degree in intoxicating liquors, and which tends to deprive him of that clearness of intellect and control of himself which he would otherwise possess. If the ability of the driver of an automobile has been lessened in the slightest degree by the use of intoxicating liquors, then the driver is deemed to be under the influence of intoxicating liquor. The mere fact that the driver has taken a drink does not place him under the ban of the statute unless such drink has some influence upon him lessening in some degree his ability to handle said automobile. *Steffani v. State*, 42 Pac. (2nd) 615.

A. M. A. Recommendations

The following recommendations were agreed on by committees of the National Safety Council and the American Medical Association:

1. Although there is no minimal figure which can be set at which there will be absolutely no effect from alcohol, the committee recommends that persons with a concentration of alcohol of less than 0.05% by weight in blood or its equivalent in urine, saliva, or breath should not be prosecuted for driving while under the influence of alcoholic liquor.
2. Between 0.05 and 0.15%, a liberal, wide zone, alcoholic influence usually is present, but courts of law are advised to consider the behavior of the individual and circumstances leading to the arrest in making their decision.
3. At 0.15%, or above, there is definite evidence of "under the influence," since every individual with this concentration would have lost to a measurable extent some of that clearness of intellect and control of himself that he would normally possess.

These limits were purposely made liberal so that no injustice would be done to the person with unusual tolerance. In order to obtain a blood alcohol level of 0.05%, a 150-lb. (68-kg.) person would have to accumulate 1 fl. oz. (30 cc.) of pure alcohol in his body. To do this he would have to drink at least the equivalent of 2 oz. of 100-proof liquor. This same person would have to accumulate 3 oz. of absolute alcohol to reach a blood alcohol level of 0.15%.

The proper interpretation of chemical test results is based on an assessment of the relative importance of conflicting social values rather than the determination of scientifically established facts.

There is little doubt that some deterioration of human capabilities is observed at very low levels of alcohol concentration in the circulating blood. If this were evident a quarter of a century ago,[2] the more sensitive and carefully controlled experimentation of modern times[3] has only served to provide additional evidence that some measurable loss of human capacities occurs after only one of two drinks (blood alcohol levels of 0.02% to 0.03%). Thus, if we were interested only in maximum safety on the highway, we would adopt the rule, "If you drive, don't drink."

One of the cornerstones of our American way of life is the element of personal freedom, the maximum liberty of the individual to do as he pleases within the restrictions of majority-approved laws. When personal freedom is too rigorously trampled on by a restraining statute, our citizenry are likely to nullify the law by refusing to abide by its provisions. For this reason the value of any regulation depends on general public acceptance of its fairness. The fate of the 18th amendment to our constitution serves as a good example of this point. Thus, any reasonable regulation concerning drinking and driving involves a steering between the Scylla of blue-nose restriction and the Charybdis of extreme libertarianism.

It would seem that a fair degree of latitude of individual freedom is permitted if we bar only those drivers in whom the alcohol-induced impairment is material. By that is meant: noticeable to any alert observant citizen and manifested by obvious interference with locomotion or balance (standing, walking, or turning), speech (indicated by slurred pronunciation or blocking of speech), or orientation (as indicated by mental confusion as to time, place, or circumstances).

Leniency of Recommendations

Realizing the wide range of human variability and tolerance with respect to the effects of alcohol, it seemed only fair to establish two limits, a minimum or floor value and a maximum or ceiling value for the blood alcohol concentration indicating material impairment—the floor value to be that concentration below which the vast majority of persons demonstrate no material abnormality and the ceiling value to be that concentration above which all persons are materially impaired.

Such delineation of zones of no influence and definite influence in all persons would necessarily leave a rather considerable middle zone in which some persons might be materially impaired whereas others could be reasonably normal. This represents a doubtful zone between the two definite floor and ceiling values.

In setting out to establish reasonable and fair limits for alcohol influence, the question first asked was: "Below what blood alcohol concentration can we safely say that no person would be materially impaired in those factors which are essential for the safe operation of a motor vehicle?" Although delicate tests are able to demonstrate impairment at blood alcohol concentrations of 0.02% to 0.03%, it was agreed that material impairment by alcohol was not observed in any person until the blood alcohol level rose to 0.05%. So this was selected as a reasonable floor value.

The adoption of a defensible and fair ceiling value was made only after much discussion and some controversy. Because a noticeable impairment could be seen in the great majority of persons at a blood alcohol level of 0.11%, it was first suggested as a ceiling value.[4] However, there are a few tolerant persons (mostly habitual users of alcoholic beverages) in whom no noticeable degree of impairment can be seen at a blood alcohol level of 0.11%. But even these show observable impairment by the time a blood alcohol concentration of 0.13% has been reached. Realizing that not all persons had been tested and that somewhere some person might be found who was still more tolerant than any seen by American experimenters, and further recognizing the fact that even skilled analysts might differ in the measurement of blood alcohol values by a margin of ± 0.01%, it was decided to place the ceiling value at 0.15% in order to make allowance for these unknown factors.

Thus the 0.15% ceiling value is recognized as one which is inordinately high and extremely conservative—a deviation which was considered to be fair in the light of our tradition of justice, wherein it is believed to be better for a guilty man to go free rather than have an innocent one convicted.

These values recommended by the committees of the National Safety Council and the American Medical Association have been found to be preeminently fair and even generous.[5] In the countries of Western Europe the limiting values are more stringent. Norway and Sweden have adopted 0.05% as the blood alcohol limit which may not be exceeded by motorists. In Denmark, Germany, and France, the limit is one part per thousand or 0.10%. So the ceiling value of 0.15%, recommended in the Uniform Vehicle Code and adopted into the statutes of 28 of our states, is in keeping with our American tradition of permitting the maximum freedom for the individual which does not interfere materially with public safety.

Suggestions have been made that, in view of saving some of the 40,000 lives which are lost annually in highway accidents, the ceiling value be lowered to 0.05%.[6] This would be tantamount to forbidding any person who has in his body alcohol equivalent to two bottles of beer from driving an automobile. It is doubtful if such a rigid limit could be enforced.

A False Interpretation

All too frequently one finds that, where chemical tests for intoxication are employed, prosecutors or judges take the position that no person with less than 0.15% alcohol in his blood should be prosecuted, regardless of the symptoms of intoxication which he may manifest. This is a perversion of the intent of the chemical testing program. Certainly where indications of alcohol influence are evident and where no element of injury, illness, or medication suggests other causes for the driver's condition, the finding of a blood alcohol concentration in the questionable zone (between 0.10% and 0.14%) justifies the bringing of a prosecution for "driving while under the influence of intoxicating liquor."

Conclusions

It is, of course, understood that the blood alcohol concentration indicates the condition of the person at the time the test was taken. What his blood alcohol concentration was at the time of the arrest or accident can be inferred with reasonable accuracy if one can establish by interrogation the time of drinking (including the time drinking commenced, the time of the last drink, and the subject's best recollection of how much liquor was consumed). It has been argued that such extrapolations are conjectural and should not be admitted in evidence. But where the chemical test has been made within one or two hours after the arrest or accident, and facts concerning the drinking are established, courts have held such extrapolations to constitute the best available evidence and, or that basis, to be admissible.[7]

When chemical tests for intoxication are properly made and interpreted in accordance with the principles outlined above, they constitute the best and most impartial objective yardstick for the measurement of impairment by alcohol. Recognition of this fact led our highest court to state (of a blood alcohol test in a negligent homicide case) "The test upheld here is not attached on the ground of any basic deficiency or of injudicious application, but admittedly is a scientifically accurate method of detecting alcoholic content in the blood, thus furnishing an exact measure upon which to base a decision as to intoxication."[8]

More People Prepay

"Public acceptance of the idea of preplanning and budgeting some of the costs of illness, injury and disability has been proved by the continued increase in enrollment under voluntary health insurance plans." That is the conclusion of a pamphlet issued recently by the A. M. A. Council on Medical Service as a supplement to its booklet, "Voluntary Prepayment Medical Benefit Plans."

Although the number of voluntary health insurance plans in the U. S., approved by medical societies, reached a peak of 84 in 1951, enrollment in these plans has continued to climb at an average rate of nearly 4 million yearly. Total enrollment neared 45 million by the end of 1957. On Dec. 31, 1945, it was less than 3 million.

The pamphlet says: "Growth in numbers of persons alone does not indicate the full story. The basis of payment of many programs has been expanded . . . and the amounts of many benefits have been adjusted so as to be more in keeping with economic trends."

The number of plans approved by medical societies has varied from state to state. Washington has 24; New York and West Virginia, 8 each; Texas, 2. Most have only 1.

IMMOBILIZATION OF THUMB IN PLASTER IS ADVISED

Physicians cluster around "live" demonstration at one of the Scientific Assembly's special exhibits on fractures, an annual favorite.

A. M. A. Scientific Assemblies

Great 'Show and Tell' Sessions Offer Advanced Education in a Physicians' Forum

The art of anesthesia had hardly emerged from the "laughing gas" era when the American Medical Association held its first annual meeting in Baltimore in 1848. But concerned though they were w[illegible] organizational problems, the assembled physicians took time to listen to [illegible] J. C. Warren of Boston, generally credited with being the first man to operate on a patient under ether anesthesia.

Dr. Warren not only told the small group of his experience but set a pattern for future meetings when he illustrated the method of preparing chloric ether. The pattern, with modifications, still holds today—108 years later.

Physicians attending the Clinical Meeting in Minneapolis next month will be seeking information and will get it from confreres who will be using modern adaptations of Dr. Warren's "show and tell" method.

The Clinical Meeting, established 10 years ago as an outgrowth of the Annual Meeting, is similar to it in content and presentation. Designed to appeal especially to the general practitioner, it will again offer a condensed postgraduate course in medicine by means of essays, exhibits, motion pictures, and color television.

Despite Dr. Warren's pioneering, the standard medical "paper" was the chief means of communicating information at Annual Meetings during the first half century of the A.M.A.'s history, but an 1899 innovation brought a marked change in emphasis. In that year, two Indiana physicians arrived at the Columbus, Ohio, session bearing jars of pathological specimens.

Renting, at their own expense, a warehouse near the meeting place, the two put their labeled specimens on display and lured their fellow doctors to the exhibit.

Their efforts were so well received that, by resolution, the A.M.A. decided to make similar displays an annual affair. The impact of the pathology exhibit was so great that, in 1902, the format was expanded to include all areas of medicine.

The two Hoosiers with their box full of wet specimens would be amazed at how their child has grown. At the Annual Meeting in San Francisco last year, 325 colorful, lighted displays of medical information were ranged aisle-on-aisle on the floor of the convention hall. Each had been carefully thought-out, planned, constructed, and shipped by a single physician or group. Each had survived a competitive screening that eliminated 200 more. The sole reward of the exhibitor was to be allowed to spend his convention days manning his display and answering hundreds of questions from all comers.

Making up the remainder of the Scientific Assembly at San Francisco were hundreds of general and specialty lectures, dozens of motion pictures, and eight color telecasts.

Programs for both the Annual and Clinical meetings are under the direction of the A.M.A. Council on Scientific Assembly. Secretaries of the sectional specialties develop their own programs for the Annual Meeting with the aid of the Council. A new program approach to be tried at the Annual Meeting next summer will be the combining of several sections to provide an across-the-board view of a single theme. Proposed topics: childbirth and liver disease. For the Clinical session, designed more for the general practitioner, the county society of the area in which the meeting is held plans the three-day session with the Council.

Show on the Road

Preparing for an Annual Meeting (and to a lesser extent a Clinical session) is not a simple task. Coordinated by Thomas Hull, Ph.D., Secretary of the Council, and aided by George Larson, Manager of Covention Services, it is nearly a self-sufficient unit.

"We are prepared to move into four walls and a roof and stage the Scientific Assembly," Larson says. He packs everything from a special wide chalk (so blackboard marks can be read from the last row) to slide projectors (in two sizes to accommodate differing transparencies). In addition, he totes along lap boards, flashlights, easels, movie projectors, lecterns, aisle lights, transparency cases, movie screens, and dozen of other items.

There is no record of the size of the Baltimore meeting room which housed the first Annual Meeting of the A.M.A., but it probably did not need to hold more than 300. So complex have housing arrangements grown in the intervening century that today only three American cities—New York, Miami Beach, and Atlantic City—can comfortably house the Annual Meeting.

More than 13,000 member physicians descended

Glowing like a city in miniature, aisle after aisle of scientific exhibits await the visiting physicians just before the opening of last summer's Scientific Assembly in San Francisco. Viewed from the convention hall's balcony (note figures seated at lower left), the lighted display offers an indication of the scope of medicine's most popular "postgraduate course."

on San Francisco for the 1958 session in June. The largest meeting ever held was in New York City in 1957, and it pulled 19,469. Convention statisticians say each physician can be counted on to attract 3.5 other persons: nurses, guests, medical students, technicians, interns, and residents. Figures show that nearly 45,000 persons were drawn to the Golden Gate City for this year's Annual Meeting.

Education on His Mind

Unlike many convention-goers, the physician headed for his Annual Meeting has education uppermost in his mind. He seeks new facets of knowledge and a new look at those areas familiar to him. How does he view this semi-annual effort? Generally, he's pleased, although he sometimes finds fault with some of the physical facilities or with the emphasis placed on certain portions of the program.

In surveys conducted among doctors who participated in two of these scientific sessions, the following comments were typical:

—"The entire meeting was worth as much as a two-week postgraduate course."

—"An excellent meeting. My only trouble was that I could not be in two places at the same time.... I'll be back next year."

—"There should be greater emphasis on psychosomatic medicine, emotional disturbances, and personality disorders."

—"At least 50% of all presentations should be left out to devote more time and intimate handling of subjects of importance to the greatest number attending."

The Clinical session due next month in Minneapolis will attract fewer guests than the Annual Meeting but will be of a similar type. Instead of 300 scientific exhibits, there may be 90. Instead of staying five days, many of the guests will remain for three.

Five Year Plan

But to Dr. Hull or George Larson plans for the Minneapolis meeting are now almost a thing of the past. They finished with that one (except for the execution phase) long ago and are now hip-deep in plans for Atlantic City next June. Even next summer's affair is well under control (the Council met with the section secretaries last month), and eyes are on more distant fields.

The A. M. A. is scheduled to be in Dallas next winter, and in Miami Beach in the summer of '60. After that comes Washington and then New York City again.

New York, Atlantic City, and Miami Beach are the only places with facilities that really fit the needs of the A.M.A's largest gatherings. These needs include a giant-sized exhibition hall, 14 meeting rooms (with ceilings high enough for motion pictures) with seating for as few as 200 and also for as many as 2,500, and lots and lots of hotel rooms. These facilities should be grouped conveniently to cut down on inter-meeting traffic problems.

Chicago, although it prides itself on being a convention town, has trouble furnishing the meeting space the A.M.A. would like. San Francisco, on the other hand, lacks hotel rooms, a factor officials say probably cut attendance last year.

But wherever they're held, A.M.A. meetings lead the list of human gatherings. After it was all over in San Francisco last June, Walter Swanson, the city's convention manager, called the A.M.A. influx "the largest mass migration of humanity in modern times outside the military."

Dr. Alphonse McMahon of St. Louis is Chairman of the Council on Scientific Assembly. Other members are Drs. J. Arnold Bargen of Rochester, Minn.; Michael E. De Bakey of Houston; L. W. Larson of Bismarck, N. D.; Carl A. Lincke of Carrollton, Ohio; Samuel P. Newman of Denver; Stanley P. Reimann of Philadelphia; Walter Scott of Los Angeles; and Henry R. Viets of Brookline, Mass. Thomas G. Hull, Ph.D., is Staff Secretary.

Doctors Spark Health Survey

A thorough study of all phases of indigent medical care is under way now in Florida, due largely to the efforts of the Florida Medical Association. Aimed at blueprinting future needs and services for medically indigent, the year-long project was launched this summer by Governor LeRoy Collins, who appointed a Citizen's Medical Committee on Health chaired by Dr. Edward R. Annis of Miami.

It was the state medical association, backed by other groups and individuals, which urged creation of the committee to study particularly outpatient services and care of the chronically ill. The committee also will make recommendations relating to maximum utilization of state health services, the role of voluntary agencies, and utilization of trained personnel.

Research by individual survey teams will complement data from state bureaus. This technique of study will examine population trends, hospitalization data, nursing homes, distinctive health and medical problems of the aged, and the possibilities of insurance for the aged and chronically ill.

A. M. A. Council Meets with Ten 'Third Party' Medical Chiefs

I propose that the medical profession and third party payers engage in a cooperative project for the delineation of criteria by which the quality, economy and improvement of medical care can be measured and judged with a fair degree of accuracy.

That statement sums up the viewpoint expressed by Dr. Warren F. Draper last month (October 17) at a meeting of the A. M. A. Council on Medical Service with medical directors of ten medical programs, most of them sponsored directly or indirectly by labor groups. (See Organization Section, THE JOURNAL, Sept. 20, 1958). Dr. Draper is executive medical officer of the United Mine Workers of America Welfare and Retirement Fund.

It was the first such conference called by the Council in its efforts to clarify third party relationships. Participants noted that the six-hour session in Chicago was marked by an air of cordiality combined with frank discussion. Later this month, according to Chairman Joseph D. McCarthy of Omaha, the Council will meet similarly with representatives of Blue Shield and Blue Cross. Next month, plans call for conferring with private insurance company officials, and also with representatives of management. Early in 1959 there will be a Council session with government representatives. "Eventually, we expect that all of these third parties may be brought together by the Council in a national conference," Dr. McCarthy said.

Following are selected comments from physicians invited to the October 17 meeting:

Herbert K. Abrams, Union Health Service Inc. of Chicago—"When any new health plan arises, the physicians who are not in it are against it—until they realize it is here to stay as it grows and matures. That is the experience of history. . . . The emphasis of our service is preventive care. Physicians have complete control over all medical care rendered. We confer frequently with the Chicago Medical Society, and all of our physicians must be medical society members . . . The A. M. A. Guides for Evaluation of Management and Union Health Centers are correct when they state that health centers 'should be allowed to prove or disprove their merit, so long as they provide care of high quality.' "

David Barr, Health Insurance Plan of Greater New York—"Our relationships with local medical societies are not deteriorating. However, these societies act and think friendly at informal meetings only. They do not follow through at their meetings of delegates when official policy is made. . . . This meeting today is very encouraging."

Cyril Costello, Medical Institute of Meat Cutters' Local 88, St. Louis—"Our program allows free choice of physician and hospital. Physicians, all of whom are part-time with the institute, must be local medical society members, must be faculty members of at least one of the two university medical schools in the St. Louis area, must be in private practice, must be board-certified in their specialty and must be a private hospital staff member. Soon we will begin a program to emphasize preventive aspects to an even greater degree than exists now."

Cecil Cutting, Permanente Medical Group—"It is a firm policy to urge the Health and Welfare Fund to offer employees a choice of joining the direct service group practice prepayment plan (Kaiser Foundation Health Plan) or joining a fee-for-service type of plan like Blue Shield, Blue Cross, or that offered by private insurance firms. . . . Qualified physicians who are not in the Permanente Medical Group, on application, are granted courtesy staff privileges at Kaiser Foundation Hospitals, which are accredited by the Joint Commission. . . . The evolution of different forms of medical care organization and different forms of prepaid medical care to meet the needs of the people is both a natural and healthy development in our free, private enterprise economy."

Warren F. Draper—"Liaison is out of the question where medical societies engage in programs of harassment against us. Yet, relationships with medical societies are improving. In West Virginia and some other states we get along well. Still, so many physicians do not know the true facts—and as a result they make the wildest statements. Satisfactory principles and good relationships between organized medicine and paying agencies can be accomplished only through the development and utilization of accurate information in place of the dubious expressions of opinion which have formed so large a part of resolutions of medical societies at every level in recent years. . . . When this health program was started I was convinced it was a unique situation peculiar to the UMWA. Now I've learned a lot—that other people, splendid people associated with other programs—have the same basic problem. We all have to work it out together. . . . Things are not so black."

Henry H. Lichtenberg, Group Health Association of Washington, D. C.—"Our patients wanted to delegate their choice of physician to others rather than accept it themselves. The plan also gave us physicians reasonable security of income and hours. . . . There are good relations with the local medical society and several of us are active in it."

Frederick D. Mott, Community Health Association, Detroit—"We expect to announce a program in the next 12 months. It will be a community-based

Chairman of the Council on Medical Service is Dr. Joseph D. McCarthy of Omaha. Other members are Drs. J. Lafe Ludwig of Los Angeles; Russell B. Roth of Erie, Pa.; H. B. Wolley of Idaho Falls, Idaho; Carlton E. Wertz of Buffalo; T. J. Danaher of Torrington, Conn.; Robert L. Novy of Detroit; R. B. Chrisman Jr. of Coral Gables, Fla.; John F. Burton of Oklahoma City, and David B. Allman of Atlantic City. Staff secretary is Mr. George W. Cooley.

program gaining counsel, not only from the United Auto Workers, but from many walks of life—the clergy, bankers, and others. It will be a health program—not just sickness insurance—with emphasis on prevention and rehabilitation. We will make certain that individual members be able to have a choice of service. We urge a personal physician relationship. All medical matters are to be in medical hands—no lay domination. . . . We are anxious to develop our program in the framework of organized medicine. If we do build hospitals, they will be open to all physicians and all patients. . . . There are many physicians devoting their lives to direct service—good men—and organized medicine will be the loser if these men are pushed aside and kept out of the house of medicine."

Leo Price, International Ladies Garment Workers Union Health Center, New York City—"Our emphasis is on preventive aspects. Service is restricted to the ambulatory level and hospital assistance—not comprehensive care—because there is lack of funds. . . . It seems to me that the challenge of this broad problem is to communicate the great work of the A. M. A. to local groups."

William A. Sawyer, consultant, International Association of Machinists, Rochester, N. Y.—"We stress preventive care. . . . I am also reporting on a projected health care plan in Rochester, a joint management-labor effort for clothing workers. It is being taken up with the local medical society now."

George Shucker, Sidney Hillman Medical Center, Philadelphia—"We want to emphasize the preventive aspect of our program because to our knowledge there is no prepaid or non-profit insurance agency that sells unrestricted ambulatory preventive care. . . . Our pattern is to seek and get county medical society approval before setting up a center. . . . We need more meetings such as these—not only with the medical directors but also with administrators of our plans."

Societies Getting Part of Medical Care Plans Report

After many months of conference and study, distribution of Part 2 of the final report of the A. M. A. Commission on Medical Care Plans will be made next week (beginning Nov. 10) to all county and state medical societies. Part 2, which consists of statistical appendices and background material, was approved by the House of Delegates last June. The seven appendices consist of:

—Characteristics of 107 miscellaneous and unclassified plans surveyed by mail questionnaire.

—A directory of 246 plans for which information was available to the Commission.

—Results of several surveys on provisions and characteristics of medical society approved prepayment plans, including Blue Shield, and group and nongroup private insurance programs.

—Results of surveys on nonoccupational medical care and occupational disability programs in industry.

—Selected statutory provisions of workmen's compensation laws.

—Information on monetary aspects of workmen's compensation.

—Selected Judicial Council opinions and House of Delegates policy statements which were considered pertinent to the Commission's inquiry.

The Commission's study attempted to determine, among other matters:

1. The nature and methods of operation of the various types of plans through which persons receive the services of physicians.
2. The effect of these plans on the quality and quantity of medical care provided.
3. The legal and ethical status of arrangements used by the various plans.

Part 1 of the final report of the Committee on Medical Care Plans, with findings and recommendations, has been completed and submitted to the Board of Trustees for review and appropriate action.

Members of the Commission on Medical Care Plans are Drs. Leonard W. Larson of Bismarck, N. D., Chairman; David B. Allman of Atlantic City; H. Russell Brown of Watertown, S. D.; John F. Conway of Clovis, N. Mex.; F. J. Elias of Duluth, Minn.; Percy E. Hopkins of Chicago; H. Gordon MacLean of Oakland, Calif.; J. D. McCarthy of Omaha; Homer L. Pearson of Miami; Leo Price of New York; James R. Reuling of Windermere, Fla.; William P. Shepard of New York; Norman A. Welch of Boston; Mr. E. J. Faulkner of Lincoln, Neb., and Mr. Jay C. Ketchum of Detroit.

Compile List of Group Practices

The significance of group practices as an arrangement through which physicians provide medical care is illustrated by a roster of group units being compiled by the A. M. A. Council on Medical Service.

The Council recently mailed a verification sheet to 1,008 groups listed in a card file compiled from membership rosters of the American Association of Medical Clinics and the National Association of Clinic Managers, and from news clippings and letterheads.

A breakdown of 822 replies from groups in the U. S., Hawaii, and Canada shows 8,958 physicians practicing in these groups. While 100 of the groups answering had only two physicians, 689 included more than two. The mailing showed 18 groups had been dissolved and 15 former two-man groups had been split into individual practices.

Physicians in group practice not yet contacted are asked to send the following information to the Council: group name, address, offices (rented or owned), number of physicians, and specialities.

Purpose of compiling the information is the publication, in a few months, of a directory of group practice units.

Expansion of Rehabilitation Units Sought in State Societies

Last spring, the A. M. A. Committee on Rehabilitation polled constituent member societies to learn whether they had committees on rehabilitation. It now finds that, of the 49 responding, 25 have such units but that "all too frequently, the Committees' activities are limited to some form of liaison or cooperation with the state's Office of Vocational Rehabilitation."

Meeting in Chicago Sept. 27, the A. M. A. Committee discussed methods of encouraging the formation of rehabilitation committees by state societies that do not now have them—and urging those that do to expand their activities.

Those discussions, not yet formalized, centered on the following possible objectives:

—Coordinate rehabilitation interests and activities within the society.

—Foster medical supervision of rehabilitation services and centers.

—Study the problems and relationships of medical, social, educational and vocational aspects of rehabilitation (see Medicine at Work, THE JOURNAL, Nov. 2, 1957).

—Inform the medical profession on the availability of rehabilitation services.

—Collect information on the establishment, operation and utilization of rehabilitation services.

—Encourage county society interest in and programs on rehabilitation.

Implementing a wide-spread concern of organized medicine with the challenge of rehabilitation, the two year old Committee on Rehabilitation is made up of one representative each from the A. M. A. Councils on Medical Service, Medical Physics, Mental Health, Industrial Health, and Medical Education and Hospitals.

Community Rehabilitation Services More Practical Than a Center

While it is important to treat "the whole man" in any effort at rehabilitation, it may be unrealistic to require that his medical, psychological, social, and vocational needs be all taken care of under one roof.

That was the conclusion reached by two A. M. A. Committees when they met jointly in Chicago Sept. 27 to discuss the practical effect of the Hill-Burton law restrictions on construction of rehabilitation facilities.

Dr. Willard A. Wright, Chairman of the Committee on Medical and Related Facilities, said his Committee's recent study of the practical applications of the Hill-Burton law showed that more emphasis was needed on rehabilitation facilities. He pointed out, however, that the present wording of the law makes it difficult for small hospitals to take part in that part of the program because it requires them to provide a rehabilitation facility which includes medical, psychological, social, and vocational services.

Noting that only 62 centers had been built with Hill-Burton aid since the category was added in 1954, Dr. Edward C. Rosenow Jr., a member of Wright's Committee, said: "That's not many for the entire United States."

Dr. Frank H. Krusen, Chairman of the Committee on Rehabilitation, said his group felt it was important to provide all rehabilitation services within the community but that these need not necessarily be within the hospital itself if to do so would be a great burden.

D. C. Rehabilitation Study Links Medicine with Other Groups

"A study [of rehabilitation] would not be complete without the opinion of the practicing physician."

Putting action to those words, the Council on Rehabilitation recently began a survey of doctors in Washington, D. C.'s metropolitan area as a part of its broad study of rehabilitation services. The Council is sponsored by the medical societies of the District of Columbia, the city of Alexandria, the Virginia counties of Arlington and Fairfax, and the Maryland counties of Montgomery and Prince Georges.

Supported in part by a grant from the federal Office of Vocational Rehabilitation, the project was begun in mid-1956 "to study existing rehabilitation facilities and to assess present and future needs." Another aim of the study is to demonstrate the role

Handy 'Handicapped'

The slogan says: "Hire the handicapped—it's good business."

E. I. duPont de Nemours and Company of Wilmington, Del., agrees that it is and has the figures to prove it. "An overwhelming majority of the more than 1,000 physically handicapped employes of the Du Pont Company have achieved average-or-better levels of job performance, safety, and attendance," the firm's Employe Relations department said recently. It based its conclusions on a study made last summer in the company's plants, laboratories, and offices.

So severe is the company's definition of what constitutes a handicap that "many employes who normally would be considered handicapped were not included in this study," an official said. Not only that, but some of Du Pont's best performers have the most severe handicaps—amputation, blindness, deafness and paraplegia.

of the local medical society in total rehabilitation planning.

The need for cooperative effort in such a project is underlined in an interim report reviewed last month by the A. M. A. Committee on Rehabilitation. The report said: "There is a growing recognition that problems do not confine themselves to jurisdictional boundaries." One of the early conclusions reached by the Council was that the physician's role in the rehabilitation partnership should be given even more emphasis than originally thought.

Chairman of the Committee on Rehabilitation is Dr. Frank H. Krusen of Rochester, Minn. Other members are Drs. Walter H. Baer of Peoria; Guy A. Caldwell of New Orleans; Oscar A. Sander of Milwaukee; and Hoyt B. Woolley of Idaho Falls, Idaho. Dr. Ralph E. De Forest is staff secretary.

Symposium Explores Medicine's Vertical Frontier

What special kind of nutritional problems must be considered in planning an interplanetary voyage? That and other questions related to the well-being of man in space are being explored this coming week in a worldwide exchange of information and ideas at San Antonio, Texas.

The Second International Symposium on the Physics and Medicine of the Atmosphere and Space on Nov. 10 through 12 will emphasize man's adaptation to space conditions, including an altered concept of time. Other specific problems scheduled for discussion involve medical and psychological aspects of launching and re-entry.

Keynoting the symposium will be an address by Major Gen. Otis O. Benson Jr. on "Common Platform of Physics and Medicine in the Advance of the Vertical Frontier." Dr. Benson is Commandant of the School of Aviation Medicine at Randolph Air Force Base, where recent studies have shown that practical space travel for humans is in the near future (see Medicine At Work, The Journal, June 15, 1957). He is scheduled to introduce Lyndon Johnson, Senate Majority Leader, as dinner speaker.

Among more than 50 civilian and armed forces scientists scheduled to make presentations at the symposium are the Air Force Chief of Staff, Gen. Thomas D. White; Air Force Surgeon General Dan C. Ogle; Dr. Hubertus Strughold, Professor of Space Medicine at the Air Force School of Aviation Medicine; Dr. Werner von Braun, technical director of the Army Ballistics Missile Agency, and Col. John Paul Stapp, chief of the Air Medical Laboratory. The conference, sponsored by the School of Aviation Medicine, is being conducted by the Southwest Research Institute.

'Lifelong Study' Is Keynote of Medical Education Conference

When does a physician stop studying medicine? Never.

Announcing the theme, "Medicine—A Lifelong Study," trilingual invitations to attend the Second World Conference on Medical Education have been mailed to physicians and other members of the health professions in the U. S. and more than 60 foreign countries. The five-day conference will open on Aug. 30, 1959, at the Palmer House in Chicago under the auspices of the World Medical Association. Collaborating in the presentations are the World Health Organization, the Council for International Organizations of Medical Sciences, and the International Association of Universities.

According to the provisional program, there will be three days of section meetings between the opening and closing plenary sessions. These sections will be concerned with basic clinical training for all doctors, advanced education for general and specialty practice, the development of teachers and investigators, and continuing medical education. The theme topic will be carried in a presidential address by Dr. Raymond B. Allen, Chancellor of the University of California in Los Angeles. Other major presentations will consider international cooperation in postgraduate education, and the value of participation in research as a component in the education of physicians.

Arrangements are being made for participants to join three afternoon tours of medical schools and hospitals in Chicago and to visit A. M. A. headquarters. At the conference scene there will be technical, medical film, and audiovisual aids exhibits. During sessions, simultaneous translation will be provided in English, French, and Spanish. Governments, medical schools, and national and international bodies concerned with medical education will be represented at the conference.

(Any person who is interested in medical education may apply for conference registration by communicating with Dr. Louis H. Bauer, secretary general of the W. M. A., at 10 Columbus Circle, New York 19.)

Founded 11 years ago, the W. M. A. is a nongovernmental confederation of 53 national medical associations representing a total membership of more than 700,000 physicians. As "the international voice of medicine" (see Medicine At Work, The Journal, Sept. 7, 1957), it has been promoting research, sounding the alarm when physicians and their patients have been oppressed, and reporting on the activities of at least 23 other international organizations as they affect the practice of medicine.

Picture of Medical Education Coming in Next Week's JOURNAL

One of the broadest, and yet most concise, pictures of medical education in the U. S. and Canada will be seen in next week's issue of THE JOURNAL. More pictorial than ever before (with scenes from at least a dozen schools), the educational issue includes material on virtually every phase of medical education during the 1957-1958 academic year. Following is a preview sampling of some of that highly significant data:

Enrollments—A new record high for the ninth year, 8,030 entering students. Four schools—Tennessee, Michigan, Jefferson, and Illinois—each with four-year enrollments of over 600. The average prospective medical student applied to four schools to gain admission—60,946 applications filed by 15,791 applicants. Over 20 times as many U. S. citizens enrolled in Canadian medical schools as Canadians enrolling in the U. S., but the exact figures (82 and 4) are quite low. One out of every 18 medical school enrollees in the U. S. was a woman (total 1,644); approximately the same proportion of graduates was female, although in four schools (Howard, Boston University, Wayne State, and Western Reserve) the graduating percentage of women was 10% or more. Of course, Women's Medical College enrolls no men.

Financing—"Less than one per cent of the nation's bill for medical care is being spent for medical education," writes Mr. A. J. Carroll, Business Officer of the State University of New York, in a criticism of "inadequate financial reports" from medical schools. He adds: "Educators, doctors, students, health personnel, legislators, government officials, university officials and the general public—all are confused about medical education, what it costs, what it means to them, what they are paying for it, and what they should be paying." But there may be clarity soon, Carroll states, as the result of a recent grant from the W. K. Kellogg Foundation to underwrite a study of medical school financing—"this study for the first time will be able to prove the financial needs of medical education, and to establish new standards of management efficiency."

Progress and Experimentation—Forty-nine of the 85 operating medical schools in the U. S. and 7 of the 12 Canadian schools reported major new developments. These include a plan at Duke University to prepare physicians who are also skilled medical research scientists; a greater emphasis on educational methods for medical teachers at the University of Buffalo; the first report on a 12-year evaluation study of the medical education program at Western Reserve; studies of the sociology of medical education conducted at Cornell, Western Reserve, and the University of Pennsylvania; and an experimental program at the University of Pittsburgh whereby medical students whose separate career-hopes lie toward research, clinical specialties, and general practice might adapt their education flexibly to reach any of those three objectives.

Two New Committees Ready for Studies on Insurance, Radiation

The A. M. A.'s two newest Committees—one whose mission is primarily socioeconomic, the other basically scientific, but both concerned with major influences in modern times—are ready to begin their separate studies.

The nine-man Committee on Insurance and Prepayment Plans, under the Council on Medical Service, held its first meeting late in September and will meet again in early January. It is considering matters relating to insurance written by private companies and by Blue Shield and Blue Cross and to prepayment health care plans.

The nine-man *ad hoc* Committee on Atomic Medicine and Ionizing Radiation, under the Council on Medical Physics, is expected to meet for the first time within a few weeks with two main objectives:

1. Identify the broad problem of ionizing radiation as it pertains to the health and medical needs of the public—including the hazards, effects, prevention and treatment of radiation exposure to mankind and the environment.
2. List the areas requiring attention in a suggested order of priority.

Less than one dollar out of five spent for medical education is contributed by the student, the American Medical Education Foundation reported this month as its annual fund drive gained headway. Formed by the A. M. A. in 1951 to aid medical schools with their financial problems, the foundation has given more than 7 million dollars to medical education in the seven intervening years.

John W. Hedback, executive secretary of the A.M.E.F., said: "Contributions come chiefly from doctors and their wives, both individually and through state and county societies. About half the money has been sent to schools specified by the donors. The other half has been divided equally among the schools."

The Troubled Employee

He Looms Large As an Economic Loss, Community Problem, Medical Challenge

Milton Golin

In one day several years ago, five employees of a large East Coast industrial firm went to supervisors to complain about their jobs: Schedules were too difficult. Co-workers were intolerable. Office equipment was no good. Other departments were uncooperative. There was too much noise—or glare—or heat—or cold. Because they also complained of backache, headache, and abdominal pain, they were referred to the plant medical office. There, a company physician who happened to be a psychiatrist listened to their gripes and relieved their hurts. He also found that only one complaint could be traced to actual work conditions. These were the true causes of the other four:

A stenographer whose boy friend had stalled her for a long time had become panicky at the thought of losing him.

An account executive was afraid he would inherit the heart disease that killed his father, and the paranoid tendencies showing in his mother.

A young salesman was ashamed that he could not make up his mind about two girls who were in love with him.

A foreman was sick with the feeling that he was to blame for his wife's depression, which led her to threaten the lives of their two children.

How much business did the salesman lose that day? What major blunder crept into the steno's work? Where did the account executive fail to make an important decision? How many workers reacted in what way to the mood of their guilt-laden foreman? These may be questions for the economist, the sociologist, the administrator. But they also are questions for the family doctor. The troubles of these four employees, as of thousands more weighed down with anxieties, concern the entire medical profession because both personal and public health are at stake on a nation-wide scale.

The American Medical Association, mindful of the many-sided problem, this year established a Joint Committee on Mental Health in Industry—made up of members and designates of the Councils on Mental Health and Industrial Health—to explore the field. All five Committee members this month are beginning their study on the premise that industry is not an island of people at work. They know that industry is part of the human community and that it is another of man's several social units. For in industry, perhaps more than in any other area of American life, we are constantly being reminded of the dissatisfactions, strife, and violence that occur among people.

There is little doubt that, by and large, these people are sufficiently attuned to their jobs so that work and private problems hardly ever come into serious conflict. At the same time, industry has its severely troubled but otherwise normal employees: The homely typist without companions. The corporation lawyer who endures his distasteful job for security though he really longs to be an artist. The machinist whose wife's illness makes him do double duty as provider and homemaker for his children. The girl on the assembly line whose home life is disrupted by an alcoholic father.

That kind of unhappy or worried employee is the "accident prone" who unmeaningly violates the safety rules and suffers one mishap after another. He is the goldbricker, the trouble-maker, the one who will lose his job and cost perhaps thousands of dollars to replace. He has the ability but not the attitude to hold his job. A psychiatrist who is making a career out of the study of mental health problems in industry, Dr. William C. Menninger, says: "From 60 to 80% of all dismissals in industry are due to social incompetence and only about 20 to 40% to technical incompetence. What may be more important, we know that one emotionally disturbed employee can mess up his whole department like the proverbial single rotten apple in the barrel, and that the cost of such a person can hardly be estimated."

There are guide lines for gauging the cost, however. In one General Motors Corporation plant of

Members of the A. M. A. Joint Committee on Mental Health in Industry are Drs. Leo H. Bartemeier of Baltimore; Leonard E. Himler of Ann Arbor, Mich.; Charles F. Shook of Toledo; W. Donald Ross of Cincinnati; and Ralph T. Collins of Rochester, N. Y., chairman. Staff secretary is Dr. B. Dixon Holland.

5,800 employees, psychiatric and psychological problems were found in more than half of the workers reporting for medical care; most actually were made physically ill by those emotional problems. California's industrial accident commission announced that in one year the state paid out 15 million dollars to compensate employees suffering from some kind of neurosis associated with an in-plant injury. According to a Chicago Association of Commerce and Industry publication, maladjusted workers cost U. S. industry at least 3 billion dollars a year through repeated job changes, alcoholism, vandalism, prolonged work absence, executive breakdowns, and other signs of mental and emotional difficulties.

One corporation sent its best technician-executive on a three-months' tour of Europe with an important mission. The man failed miserably. Only much later was it learned that his wife was mentally ill and that he was worried about her and about conditions at home all the time he was away. His wife's illness was an enormous liability to the company, which might have saved itself expense, and saved the executive anguish, if a physician had picked up hints of the difficulty in a periodic examination or in day-to-day contacts with the man.

Who Are the Helpers?

Doctors employed in industry have many allies, both within and outside the profession, to help them detect such danger signs. Foremost, of course, is the family physician. As health advisor he, more than anyone else, is in a position to do a preventive job by minimizing the effects of his patients' personal problems. This should make the general practitioner a key man for maintaining mental health in industry. Other key figures are industrial nurses, supervisors, personnel officials, counsellors—and psychiatrists. Unfortunately, although most companies accept all of these individuals as essential contributors to mental health in industry—a surprisingly large number hesitate to employ the one most concerned—the psychiatrist—on a full-time basis. One corporation president commented: "Sure, psychiatrists are all right, but if we have one on the regular payroll, people will wonder what's different about our employees."

In all of the United States there are only a half dozen companies which employ full-time industrial psychiatrists. These include Du Pont, International Business Machines, American Cyanamid, America Fore Insurance Group, and Metropolitan Life. However, at scores of other firms—such as Caterpillar Tractor, Kraft Foods, American Telephone and Telegraph, and the Detroit automakers—psychiatrists work part time or on a consultant basis. According to a survey made this summer by the *Wall Street Journal* (which calls mental illness "industry's top medical problem") company psychiatrists seldom give long-term treatment. Dr. Alan A. McLean, full-time psychiatrist at IBM, said: "We're not here to compete with private practicing physicians. Our job is to diagnose emotional disorders and determine whether they should be referred for psychotherapy."

Industrial nurses play a vital role in mental health. One alert nurse in a Western Massachusetts metal-working concern several years ago wondered why a craftsman showed up twice within a short period for treatment of finger injuries caused by careless handling of his machine. She drew him out and learned that he was worried about where to turn for aid for his wife, pregnant at middle age. The nurse simply told him where to find a social agency that could help his wife. No psychiatrist, she nevertheless provided the kind of counselling that nurses, personnel men, foremen, and others may develop under the guidance of a psychiatrist or other physician. The guidance must be proper, of course, for misguidance may easily do much more harm than good.

Pioneering Study

An example of proper guidance is in the Western Electric Company, whose Hawthorne Works in Cicero, Ill., 32 years ago became the laboratory for a pioneering study which has not yet been equalled in thoroughness and intensity. The study was intended to find out what kind of lighting would help boost production. But the plotting of one "average output" curve led to another until, before long, research was going on full blast into what makes a worker tick. The researchers found that better lighting increased output, all right, but that reduced lighting also increased production. Why?

That five-year experiment demonstrated that by merely exhibiting interest in workers—as each re-

The Desk Set—One Man's Worry

Officials of an East Coast business firm were puzzled over the change in one of their executives after he was transferred to another job in the plant. He was receiving the same salary and he had equal responsibilities, but, despite assurances that it was a lateral shift only, the man developed all the symptoms of acute anxiety. He lost sleep, his appetite fell off, and he could not concentrate on his work. By chance, Professor F. J. Roethlisberger of the Harvard University School of Business Administration happened to be conducting a study of that company. He recognized that an unofficial symbol of status there was possession of a twin pedestal desk. The executive had been transferred to a desk with only one pedestal. At Roethlisberger's suggestion, the man was given a two-pedestal desk and his symptoms disappeared almost immediately.

New Problems, New Needs

The business community must bear at least some of the responsibility for creating mental health problems of its employees, according to *Business Week*. An article in that national magazine states: "Executives fail to realize that they themselves are partly responsible for changes that have raised new worker problems. . . . Fifty years ago a man followed his father's footsteps, used his hands to produce a finished product and he could take satisfaction in his handiwork. Today the worker is separate from the finished product. He is not able to feel the same satisfaction in seeing a job well done." The article also states, "The big problem for industry is finding the right doctor. Specifications are exacting. He has to know his medicine and he has to be a good listener when it comes to sob stories. He has to be an intermediate between worker and management without looking like a company spy. In short, he has to be a combination of Dr. Christian of the movies and an army chaplain."

searcher did—management was able to make them happier and more productive. It did not take long for the company to realize that a counselling program would sustain that interest. Several score Western Electric counsellors, skilled listeners who were always present, encouraged the worker to talk about anything at all—never interrupting, never arguing, never giving advice. Often the result, according to the company, was that employees seemed to talk their troubles away, re-examined their thinking in the sound of their own words, and acquired a social skill in relationships with fellow employees.

An echoing comment comes from Dr. Leo Wade, medical director for the Esso Standard Oil Company, who says: "Many times a worker will come in with a complaint and all he needs is a sympathetic ear. After he talks to us awhile and gets his trouble off his chest, he begins to feel better."

Western Electric cites a good example of this, an employee of 20 years' experience who began hitting the skids until he was doing the lowest grade of work in his department. He became so edgy that no one dared approach him for fear of triggering an accident at his machine. His locker was a small drugstore of medicines. He complained that even when his back was turned he could feel the foreman's eyes boring through him—always spying on him. Company counsellors uncovered an extreme case of social isolation. The man lived alone, locked himself in his room each evening, dosed himself with whisky and medicines, had no friends, and rarely visited his only relative.

After three weeks of skillful interviewing under medical supervision, nothing more than what might be called friendly chats, the employee's fears faded away. His work improved, he began to take an interest in co-workers, and his rise again to a responsible position of leadership became a matter of course.

Importance of Leadership

Of all factors that influence mental health in the office and factory, the foremost is leadership. The special pressures on many an executive—frustrations, fear of failure and feeling of insecurity—inevitably will either warp or stabilize the attitudes of people under his leadership, depending upon his own approach in handling those pressures. "That is why the executive's well-being is of vital concern, not only to himself but, even more importantly, to those he leads," says Dr. Ralph T. Collins of Rochester, N. Y., Chairman of the new A. M. A. Joint Committee on Mental Health in Industry, and neurological and psychiatric consultant for the Eastman Kodak company. "There are cases of companies which reached the brink of bankruptcy because they had emotionally sick men at the helm—men particularly difficult to treat because of their position. There are supervisors who are autocratic and domineering, who are unable to make a decision or to delegate responsibility, who are bad-tempered, who are unreasonable, who are unable to win respect.

"Fortunately, this kind of executive is in the minority for the very reason that our economy places such a high premium on production; he is less likely to survive in competition with the executive who does gain the respect and added effort of his workers."

That is only part of the reason, however, and it may even be the wrong part. For the core of our mental health problem in industry, according to Dr. Menninger, is "a mixing of our values system. We tend to focus on and hear about one side of industry, which has as its chief goals the increase of production and the increase of profits. But money won't bring or buy the loyalty or high morale we strive toward. So much of job satisfaction depends on the personal values that are gained in human relationships through mutual respect and dignity, confidence and belonging and, yes, love."

The Problems

That concept indicates that, while management generally may be aware of its deep involvement in the worker's personal problems, it also needs *medical guidance in dealing with employees* so that emotional difficulties will not be created or aggravated. Says Dr. Collins of the A. M. A. Committee: "Meeting that need represents the biggest task of the physician—whether he is a full-time industrial psychiatrist, one of the 5,000 doctors who devote their careers to the broad field of occupational health, or one of the 20,000 other physicians who serve industry part time or on call (see Medicine At Work, The Journal, March 30, 1957). The doctor employed in industry can work two different ways to preserve mental health. He can see that the worker gets emotional first aid in the form of brief psychotherapy after early diagnosis, and he can emphasize preventive aspects in his role as consultant in labor and industrial relations."

What Is Being Done

Actually, this is what many physicians, in cooperation with management and labor, are doing to brighten the mental health picture in factories and offices—and, thereby, in communities—across the land. These are other current developments pointing toward progress in this expanding field:

—This month, on Nov. 20, the A. M. A. Joint Committee on Mental Health in Industry will meet in Chicago for the first time to plan its program.

—Since last February, under the auspices of the American Management Association, top executives from scores of business firms have been gathering at Saranac Lake, N. Y., for concentrated sessions on human factors in industry. The courses are conducted by psychiatrists (like Dr. Collins) and other authorities in the field.

—Three weeks ago the New Jersey Industrial Health Conference devoted half of its day-long program to emotional factors in the work environment.

—More and more state and local medical groups are establishing committees on mental health in industry.

—The World Health Organization this year is launching *a study of the effects of automation on* mental health.

—This year, for the first time, the Industrial Medical Association created a committee on mental health in industry.

—Work is being completed now on the first phase of a massive study of human relations in industry. The project, begun three years ago and financed partly by a grant of the Rockefeller Foundation, is being conducted by the Menninger Foundation's clinical staff. In order to gauge the measure of corporate actions upon workers' mental health, researchers so far have conducted "in-depth" interviews of more than half of the 1,900 employees of the sprawling Kansas Power and Light Company. Using this study as a base, the Menninger Foundation hopes to develop a program having far-reaching effects on mental health in industry.

Promise of the Future

Those developments point toward the solution of a host of complex problems evolving out of our expanding industrial society. But what kind of

Foremen rate "good wages" as the most important condition of their jobs, but the men who work under them believe that appreciation for good work is most important—according to results of a survey reported by the Labor Relations Institute of New York. The Institute prepared the following chart to show how both groups feel on this point:

JOB CONDITIONS	WORKER RATING	FOREMAN RATING
Appreciation for good work	1	8
Feeling "in" on things	2	10
Help with personal problems	3	9
Job security	4	2
Good wages	5	1
"Work that keeps you interested"	6	5
Possibilities for promotion	7	3
Personal loyalty to the workers	8	6
Good working conditions	9	4
Tactful discipline	10	7

program can be formulated to prevent these problems from arising in the future?

—Already, there are mounting efforts by leading psychiatrists to instill upon top management officials the idea that there should be greater emphasis on "capacity for human understanding" in the rating and selection of executives. Dr. Menninger puts it this way: "When I say a leader must understand men, I don't mean understanding from a common sense point of view alone. I mean from a very uncommon sense point of view. The kind of a leader that I would wish in many, many high places is the man who has some understanding of personalities, their structure and function, how they work, and who knows of the unreasonableness in all of us and the hostilities we all have."

—Growing numbers of the former mentally ill, with the cooperation of management and labor, are being rehabilitated into productive employment.

—Influential advisors to both labor and management finally are putting across the point that perhaps industry is remiss when it looks upon the neurotic employee as a liability who should be either fired or swept under the rug of some remote department. In a book published recently, one psychiatrist views such an employee as a valuable weathervane—much as miners value canaries in coal pits as alarm-ringers of danger.

—Carrying that point a step farther, top industry executives are beginning to recognize that business administration at all levels is defeating itself and the nation at large when it attempts to screen out emotionally tense employees or job seekers. Dr. Frederick W. Dershimer, who was hired as a full-time psychiatrist for E. I. du Pont de Nemours in 1943, said: "The most valuable people are sometimes screwballs. If you do a good enough screening job you may get people who are perfectly normal. But you will have screened out people who discover things like Nylon."

Mental Health—A Definition

Mental health is a medical goal not only in industry but in agriculture and other occupational fields as well. Here is one definition given at an A. M. A. Rural Health Conference by Dr. J. Lester Henderson, a psychiatrist, while he was chairman of the Mental Health Committee of the Washington State Medical Association: "Mental health is that state of mind and feeling that looks on life as basically good. The mentally healthy individual arises in the morning with confidence in his heart, expectation in his attitude and a grin on his face. He is optimistic and friendly, with a capacity for patience and trust. He can take frustration and disappointment without being embittered. He can find new goals if the ones for which he was trying become unobtainable, and in his prayers he can express feelings and ideas beyond what he could express to his parents."

Those trends are bright spots which could offset darkness as medicine and its allies seek to maintain mental health in our growingly complex occupational environment. An over-riding benefit might easily be overlooked in this search. It represents the greatest reward of all: The personal well-being of the nation in generations to come. When a boy hears his father constantly complain about his job, he is likely to have a similar attitude toward his own work and employer. Here we see contagion feeding upon itself. But while there are indications that mental illness may be as communicable as the common cold, there also is ample evidence that mental health in its most beneficial sense is even more "catching." Says Dr. Collins of the A. M. A. Committee:

"The work that men do is an essential part of their lives, not mainly because by it they earn bread but because a man's job gives him stature and binds him to society. The worker who is happy in his job, with confidence in his management and cooperative relations with his coworkers, will spread his contentment throughout the community."

CHILDREN IN HOSPITAL

FOR A CHILD to be removed from his parents, placed in strange surroundings, and subjected to a variety of unpleasant procedures is apt to be psychologically traumatic under the best of circumstances. The extent of such a trauma depends on such factors as the age of the child, the length of his hospitalization, the closeness of the parent-child relationship prior to admission, how well he was prepared for the new experience, the nature of the child's illness, the nature of the required treatment, the basic personality of the child, the frequency of parental visits, the type of nursing care provided, and the presence of other children on the ward. Illingworth [1] elaborates on many of these factors. A child naturally has a feeling of helplessness but this does not cause undue anxiety unless the situation appears to the child to be a threatening one. If an anesthetic must be given the child may fear that he will be or that he has been mutilated while he is or was asleep.[2] Often the child's anxiety is a direct reflection of the anxiety of the parents.

Illingworth calls attention to the fact that the child who cries when parent leaves after admission or at the end of every visiting hour is an overdependent child who also cried when left at home with a sitter for a few hours. Immature parents unconsciously encourage this because they feel flattered by such a show of dependence or, as they prefer to call it, devotion. There is no doubt that parental factors can aggravate the psychological problems of a child in a hospital. These include a poor parent-child relationship before admission, lack of appropriate preparation for admission, failure to visit the child daily, failure to maintain reasonable discipline even in a sick child, and making promises that cannot be kept such as promising that child can come home "tomorrow." The worst type of parent-induced anxiety possible results from the practice of some ignorant parents of telling a well child that if he does not behave the doctor will come and take him to the hospital. Woe betide such a parent if the child ever does have to go to the hospital. The manifestations of psychic trauma in a child who stays in hospital only a short time may be crying, becoming abnormally subdued, poor appetite, enuresis, or tantrums. After a long stay a child may show general apathy and on return home he may react with regression to infantile behavior such as enuresis, excessive clinging, nightmares, fearfulness, tantrums, or speech difficulties. The commonest fears are fear of the dark; of strangers; of nurses, doctors, or anyone dressed in white; and of strange places.

Anything that can be done to prevent or minimize the psychic trauma attendant on the hospitalization of children is almost sure to be worth the effort. Some admissions could be avoided through greater use of a good outpatient service. If a child must be admitted and it is not an emergency, a preliminary visit to the hospital will make the surroundings less unfamiliar especially if the child can meet the nurse who will take care of him and see that other children there are reasonably happy. Some hospitals give parents helpful pamphlets about preparing a child for hospitalization and provide the child with a coloring book emphasizing the pleasant aspects of the projected stay. On admission it is well to allow the mother to stay with the child until he is in bed and has had a few minutes to adjust to his surroundings, or, if the child is not too sick, he should be admitted to the ward playroom instead of bed. Adjustments are always easier in a children's hospital where personnel and facilities are all geared to the needs of the child. If the child must be admitted to a general hospital it should be to a children's ward. Daily visiting by parents should be encouraged. Even though a child cries when his parent leaves it is better that he be upset for a few minutes every day than to feel that he has been deserted or is being punished.

Nurses on duty in a children's ward should pick up and cuddle the smaller children and must learn to recognize that a quiet child is not necessarily a good child or that a child who cries or shouts is not necessarily a bad child. The nurse should act as a mother substitute and do all in her power to comfort a distressed child whatever the cause of the distress may be.[7] Some hospitals allow the mother to be admitted as a companion if the child is under 5 and is in for a short stay. This provides a good experience for the mother in how to care for a sick child, permits the child to retain a feeling of security, and in some cases (although this should not be so) makes the staff more considerate in their treatment of the child. Insofar as possible the child should be kept busy and if toys are provided they should be of a sort to give scope to his imagination. The diet should be balanced and the food attractively served. When unpleasant procedures are necessary they should be done quickly and as painlessly as possible.

Of all the preventive measures, however, a good parent-child relationship is the best. In explaining to a child that he must go to the hospital the parent should never lie to him. It is unwise to go into elaborate details but important to let child talk and ask questions so that any misconception on his part can be corrected in simple terms. This must be done in a straightforward manner and without trying to shame or ridicule him.[5] After an operation the child should again be encouraged to talk about any fears he may have so that erroneous ideas about what was done can be dispelled. If a child is unduly disturbed emotionally before going into hospital psychotherapy should be given before admission if an emergency operation is not required.

Lest the impression be given that only psychic harm can come from hospitalization it should be added that with proper preparation the experience may be a constructive rather than a traumatic one in that it aids the child in growing up and establishing an independent outlook on life. The association with other children and with adults, especially those of a psychologically oriented hospital staff, can also be beneficial.

WOE AND WORK

Only a few years ago wives, sociologists, and clergymen the country over were viewing with alarm the picture of the husband so engrossed in his job that, instead of frolicking with his family at the end of a day's work, he would bring home a briefcase crammed with more business toil. The situation still may be an alarming one, but now there is a kind of reverse phenomenon that poses a more formidable problem: the employee or executive who carries his home troubles to work.

This is a problem of little-realized but huge proportions, affecting not merely the individual and his family but the community and even the nation at large. The economic loss is staggering, the attendant interpersonal impacts are imposing, and the resulting total challenge to medicine is a great one indeed. A special article on page 1363 of this issue in the new Medicine at Work section notes that, while the vast majority of leaders and employees in American business and industry are temperamentally in tune with their jobs, there is enough personal worry and disturbance in their ranks to pose a real threat to the well-being of the labor force.

The threat is a jeopardy to mental health but it also endangers physical health. This is because the worker suffering from "chronic anxiety" stands as a double hazard. On the one hand, personal tensions which may preoccupy his thoughts create a distinct accident peril to himself and fellow employees, particularly where men are clustered around machinery. At the same time, these off-the-job disturbances—whether manifested at work in gripes said aloud or in deep-seated suspicions smoldering silently—carry a germ of communicability which might infect co-workers as surely as a sneeze might infect them with the common cold.

This is where the family doctor can play a starring role. By serving as a case-finder of maladjusted workers in his everyday practice, and following through on a broad scale with early therapy and preventive measures for all of his patients, the physician can achieve a dual purpose: transform a half-happy drudge into an effective and satisfied employee, and help solve a community health problem by raising the level of occupational fitness. The effort may also serve to raise the country's standard of living. For it is a fact that accidents, gold-bricking, excessive work absence, trouble-making, and other signs of employee maladjustment cause a tremendous dollar loss in industrial output. Two industrial psychiatrists in a book published this year estimated the annual loss at "hundreds of millions of dollars." The Chicago business magazine, *Commerce*, figures it closer to three billion dollars a year.

Whatever the cost shown on corporate ledgers, it is the debit in terms of human suffering which is felt the most. Because of the growing urgency of this multiphasic problem, the A. M. A. Board of Trustees last spring directed that a Joint Committee on Mental Health in Industry (under the Councils on Industrial Health and Mental Health) be formed to explore the field. The Committee is scheduled to meet for the first time this month. What it finds, and what it eventually will recommend, should illustrate again that the profession is just as concerned with community building as it is with personal healing.

The Committee is scheduled to meet for the first time this month. What it finds, and what it eventually will recommend, should illustrate again that the profession is just as concerned with community building as it is with personal healing.

COUNCIL ON MEDICAL SERVICE

ALABAMA COMMUNITY MEDICAL RATING SURVEY

The Community Rating Schedule, prepared under the direction of the Council's Committee on Medical and Related Facilities, has been utilized in several statewide surveys by medical associations. This schedule was designed to aid a community seeking more medical care to determine (a) the need priority, from the standpoint of the community, and (b) the desirability, from the standpoint of the physician. The state medical associations that have used the schedule have a means of distinguishing the communities that need more medical care from those that either do not need more physicians and/or could not support one.

In 1954, after participation in two regional placement service conferences, sponsored by the A. M. A.'s Council on Medical Service, the Committee on Public Relations of the Medical Association of the State of Alabama established a Physicians Placement Service under the direction of Mr. W. A. Dozier Jr., at that time the association's director of public relations and now the executive secretary of the state medical association. A comprehensive set of questionnaires was developed for the purpose of securing pertinent data from physicians seeking a location for practice and from communities seeking a physician. The physicians were given the information on communities seeking more medical care and the communities were supplied with the names of physicians interested in a location; after that it was up to the community and the physician to make their own contacts and arrangements. After the service had been in operation for four years, the Alabama Committee on Public Relations reviewed this phase of their program, as well as related statistics on the distribution of medical care in the state. It was noted that Alabama, with a 1957 population of 3,061,743 and 2,239 physicians, had a population-physician ratio of 1,367. The population-physician ratio by individual county ranged from 954 to 7,435, with a minimum of two physicians in any county. During each of the past five years there had been a net gain in the number of new physicians in the state over the total number lost by death and by removal to other states. It was found that approximately one-third of the physicians requesting location information had been directly or indirectly placed by the Alabama Physicians Placement Service. In order to better serve the steadily increasing number of physicians requesting location information and communities seeking additional medical care, the Committee felt that this would be an opportune time for a community medical rating survey.

Purpose

To those interested in making the survey, the sixfold purpose of the proposed study fell into the following areas: "(1) To determine where and to what extent additional medical care is needed; (2) To assist physicians in locating in communities where they can practice to the full extent of their training; (3) To evaluate the medical desirability of a given location from the standpoint of a physician seeking a place to practice; (4) To assist communities in improving their medical desirability rating; (5) To submit statistical information to corroborate the facts revealed in this survey; (6) To assist the State Board of Censors in placing to the best advantage the six students, now on state scholarships at the University of Alabama Medical College, who have agreed to practice in communities of 10,000 population or less, when they graduate."

Procedure

The Committee on Public Relations appointed a Survey Committee composed of J. Michaelson, M.D., Foley, chairman of the Committee on Public Relations; R. O. Rutland Jr., M.D., Fayette, chairman of the subcommittee on physician placement; and Mr. W. V. Wallace, Montgomery, executive assistant of the Medical Association of the State of Alabama. The president of the medical society in each county to be surveyed was requested to ask one member of his society to serve as a representative on the Committee when a town in his area was under evaluation.

Initially, the town clerks of 301 Alabama municipalities, with a population of 25,000 or under, were sent a questionnaire relative to the available medical care in the area. An accompanying letter of explanation was co-signed by Mr. W. V. Wallace, member of the Committee, and by Mr. E. E. Reid, executive director of the Alabama League of

Municipalities. In the cases where a response was not received to the first letter, a second letter and form covering county information was sent to the president of the local Chamber of Commerce. Concurrently, E. Julian Hodges, M.D., Scottsboro, president of the Alabama Academy of General Practice, mailed a similar questionnaire and letter of explanation to an Academy member in each county. Follow-up letters were sent where necessary to secure a response. These combined mailings brought replies from one or more towns in 62 of the 67 counties in the state.

After the questionnaires were returned and tabulated, the Survey Committee made a pilot study of three towns: Phil Campbell (population, 758), Coffeeville (211), and Grove Hill (1,443). Three weeks prior to the visit to each community, letters of explanation, including the date for a scheduled visit by the Committee, were sent to the communities and also to the president and secretary of the respective county medical societies, inviting them to attend the community medical evaluation meeting. At each of these three meetings the Community Rating Schedule was applied by the Committee in conjunction with the local group. Distribution was made in each community of the booklet, "YOUR TOWN . . . . Weighed in the Balance—CAN IT SUPPORT A DOCTOR?" This concise, informative booklet, prepared by the Medical Association of the State of Alabama, raises questions to aid the community in looking at itself, as a new citizen would see it, and offers "suggestions for keeping a doctor once he arrives."

After the compilation of the information secured through visits to these three communities, the program was outlined for the other areas to be visited. The Committee felt that the participation and cooperation of the local physicians was exceptionally good. Mass meetings had not been requested in any community, but attendance by local citizens sometimes reached 65. The visiting committee felt that the discussion on the part of the townspeople showed widespread interest in the problem and also careful preparation for the meeting.

Out of the eight months required to complete the survey, four weeks were used to visit the 38 communities located in 24 counties. Because of the thorough preliminary planning, an average of three communities could be visited each day.

The community surveys have been mimeographed and are being made available to physicians upon request either to the state association or to the Council on Medical Service.

Results

Results of the survey may be listed as follows: First, during the survey the Committee found much community information that would be valuable to a physician seeking a location for practice, but not previously listed in the Alabama Physicians Placement Service files. For example, a number of equipped medical facilities had been built by towns hoping to secure a physician; new industries had been built in a number of areas, as well as new churches, schools, and additional recreational facilities. Second, in the short time since the Community Rating Schedule has been applied, 2 of the 38 towns visited have secured a physician. Third, the 1953 Legislature of the State of Alabama created six state scholarships available each year for medical students at the University of Alabama Medical College in Birmingham. Students who are accepted for this program agree to practice in an Alabama town with a population of 10,000 or under. If the physician practices in the approved town for five years, he does not have to repay any part of the loan, otherwise he repays the loan as provided by the Alabama law. The first six physicians participating in this program are completing their internship in 1958. The survey offers excellent resource material for these physicians who plan to practice where there is a medical need. Fourth, according to the report prepared by the Committee, "if nothing else were accomplished except the personal contact made with these communities the Committee feels that the time, money and effort involved were justified in enhancing the relationship and prestige of the medical profession in Alabama with these communities."

From the survey statistics it is interesting to note that only 3 of the 62 counties responding to the mailed questionnaire had noticeable discrepancies between the physicians' opinion about the need for more physicians and the laymen's opinion on the matter. In one county the physicians felt the greater need, in the other two the laymen expressed a greater need. The population-physician ratios in these counties were 1,601, 1,258, and 954. The report that has been prepared does not mark the end of the Alabama Community Rating Program. The Survey Committee is to become a permanent part of the Committee on Public Relations. An evaluation visit will be made to each new community to be listed by the Alabama Physicians Placement Service.

The physicians of Alabama, their association staff, and the laymen of the state are to be commended, first, for their recognition of the fact that more medical care is needed in the state, second, for their cooperative study to determine where the need is greatest, and third, for their plans, already in operation, to do something concrete to bring more medical care to areas in need.

MEDICAL NEWS

CALIFORNIA

Dr. Farber Appointed Assistant Dean.—Dr. Seymour M. Farber, head of the continuing education program at the university medical center since 1955, has been appointed assistant dean of the University of California School of Medicine, San Francisco. Postgraduate medical education will be Dr. Farber's area of special responsibility. About 2,500 practicing physicians participate annually in the postgraduate courses at the medical center in cooperation with bay-area hospitals and in outlying northern California communities. These courses range from the one-day symposium to a full-time three-months' course in the use of radioisotopes. Other assistant deans of the medical school are Drs. Robert H. Crede and Malcolm S. Watts. Dr. Leon Goldman is associate dean.

New Cardiovascular Research Institute.—At the dedication of the Cardiovascular Research Institute October 30 at the University of California Medical Center, San Francisco, the principal speaker was the Honorable Earl Warren, Chief Justice of the United States Supreme Court. Others participating in the dedication were president Clark Kerr of the University of California Medical Center; Dr. John B. D. M. Saunders, dean of the School of Medicine, and Dr. Julius H. Comroe, Jr., director of the Cardiovascular Research Institute. The institute, which occupies the 13th floor of the new Herbert C. Moffitt Hospital, brings together members from 13 departments of the School of Medicine and more than 20 research fellows and trainees. Its laboratories, which have already been occupied for several months, are devoted to basic and clinical studies of the functions and diseases of the circulatory system and related organs. Dr. William J. Kerr, emeritus professor of medicine, proposed the establishment of the institute before World War II. After the war appropriations for building the Moffitt Hospital included funds to construct the shell of an additional floor for the eventual use of such an institute. Among the agencies and organizations that have made grants to complete this floor and purchase laboratory equipment are the U. S. Public Health Service, California Department of Health, and the Heart Associations of Alameda, Merced, San Diego, San Francisco and Yolo Counties.

CONNECTICUT

State Society's Clinical Congress.—The 33rd clinical congress of the Connecticut State Medical Society and the Yale University School of Medicine, New Haven, was held Nov. 5 in Hartford featuring nine illustrated lectures on new advances in surgery and patient care on subjects such as modern treatment of infectious diseases, care of staphyloccal infections in infants, use of drugs in kidney ailments, degeneration of the arteries, advances in gastrointestinal surgery, methods of nutrition in surgical patients, and treatment of illness in pregnancy. The program was arranged by the society's Committee on Postgraduate Education on which Dr. Arthur Ebbert Jr., assistant dean, Yale University School of Medicine, was chairman.

DISTRICT OF COLUMBIA

Annual Scientific Assembly.—The 27th annual scientific assembly of the Medical Society of the District of Columbia will be held in the Statler Hilton, Washington, D. C., Nov. 24-26. The scientific program will comprise a series of conferences, workshops, and panel discussions on congestive heart failure, fluid and electrolytes, recent advances in virology, problems in the management of surgical patients, toxemia of pregnancy, every-day psychiatry in general office practice, discussions on general questions, and clinicopathologic conference. There will also be a medical motion picture program, exhibits, luncheon meetings sponsored by the George Washington University Medical Society and the Georgetown University Medical Alumni Association. A benefit buffet supper for the Woman's Auxiliary's Nursing Fund and the annual dinner for doctors office staffs are planned. Active and life members are entitled to one ticket without charge to the Medical Society's luncheon on Monday. Nonmembers and associate and affiliate members may purchase luncheon tickets for $3.75 each.

GEORGIA

Conference on Nutrition in Athens.—"Better Foods for Better Nutrition," will be the theme of a joint Conference sponsored by the Divisions of Foods and Nutrition, and Food Procession of the University of Georgia to be held March 4-6, 1959, at The Center for Continuing Education, University of Georgia, Athens. This Conference is planned for persons engaged in research, extension, and teach-

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. *Programs should be received at least three weeks before the date of meeting.*

ing of foods and nutrition. Special attention will be given to industrial and institutional problems in processing, handling, and serving foods.

ILLINOIS

Chicago

Lecture on Growth and Genetics.—The Chicago Medical School and the Squibb Centennial Lecture Committee will present Theodore T. Puck, Ph.D., chairman, department of biophysics, University of Colorado Medical Center, Denver, in a lecture, Nov. 10, in the Sarah Morris Amphitheatre, Michael Reese Children's Hospital, at 4:00 p. m. The subject will be "Growth and Genetics of Somatic Mammalian Cells in Vitro." Again, on Nov. 12, at 9:30 a. m., at Mount Sinai Hospital, Dr. Puck will address a seminar on the application of single cell plating techniques to problems in medicine. Both meetings are open to those interested.

Heart-in-Industry Conference.—The 6th Heart-in-Industry conference, sponsored by the Chicago Heart Association and the Chicago Association of Commerce and Industry, will be Friday, November 14, at the Hotel Sherman. This conference was made possible by a grant from the Visking Corporation of Chicago as a memorial to the late Gustav Freund II. In several workshop groups, the discussions will concern a review of two case histories of workers with cardiac disease. The featured speaker at the luncheon will be Dr. Paul Dudley White of Boston. Following adjournment at 2:00 p. m., all participants are invited to attend a special discussion by the Illinois Governor's committee on employment of the physically handicapped in the Bal Tabarin Room of the Sherman Hotel.

KENTUCKY

State Medical Election.—At the annual meeting of the Kentucky State Medical Association, Louisville, Sept. 23-25, the following officers were elected: Drs. Robert W. Robertson, Paducah, president; Irvin Abell Jr., Louisville, president-elect; Marvin A. Lucas, Louisville, Thomas O. Meredith Jr., Harrodsburg, and Lillard F. Beasley, Franklin, vice-presidents; Woodford B. Troutman, Louisville, secretary (re-elected); and Delmas M. Clardy, Hopkinsville, treasurer.

MARYLAND

Dr. Wilbur Will Give Friedenwald Lecture.—The 11th annual Friedenwald Memorial Lecture on the diagnosis and management of functional gastrointestinal disorders will be given November 11 at 5:00 p. m. at the University of Maryland School of Medicine, Baltimore, by Dr. Dwight L. Wilbur, clinical professor of medicine at Stanford University School of Medicine, San Francisco, and president of the American College of Physicians.

MASSACHUSETTS

Benjamin Waterhouse Society.—The Benjamin Waterhouse Medical History Society will meet at the Massachusetts Memorial Hospital, Nov. 17, when, following a dinner for members and guests, Dr. Carl W. Walter, associate clinical professor of surgery, Harvard Medical School, Boston, and surgeon, Peter Bent Brigham Hospital, will lecture on "Asepsis in the 19th Century." All persons interested are invited to attend the medical history session. The president of the society is Dr. Lamar Soutter and the secretary is Dr. John J. Bryne, both of Boston.

Dr. Hastings Goes to California.—A. Baird Hastings, Ph.D., head of the biological chemistry department at Harvard, will retire December 31 then join the Scripps Clinic and Research Foundation at LaJolla, California, where he will continue his research in intermediary metabolism and in the application of biochemistry to the study of disease. At Harvard he will become Hamilton Kuhn of biological chemistry emeritus, the second to hold that professorship; the first of whom was Dr. Otto K. O. Folin. Dr. Hastings was appointed professor of physiological chemistry at the University of Chicago in 1926. He joined the faculty at Harvard in 1935 as head of the biological chemistry department.

The William James Lectures.—Harvard University has announced that Donald B. Lindsley, Ph.D., professor of psychology and physiology, University of California School of Medicine, Los Angeles, will give nine William James Lectures on successive Mondays beginning October 20; thus the next lecture in this series will be November 10 in the Allston Burr Lecture Hall A, 4:15 p. m. The general subject of the series is "Brain Organization and Behavior." The announcement states that the lectures will deal with new knowledge of the nervous system that has certain importance. Prof. Lindsley is said to be best known for his work with the electroencephalograph. Formerly he was a fellow of the National Research Council in the Harvard University physiology department, assistant professor at Brown University, and professor of psychology at Northwestern University.

MICHIGAN

University Gifts and Grants.—Gifts and grants accepted by Wayne State University's Board of Governors, Aug. 20, included $120,670 from the U. S. Public Health Service, to be used in various research projects. From the Michigan Heart Association, $53,050.50 will be used to continue research on heart disease. A total of $45,500 was accepted from the McGregor Fund, of which the department of psychiatry will get $24,000, while $21,500 will support a program in psychotherapy over a two year period under the direction of Ross Stagner, Ph.D., College of Liberal Arts. The Kresge Foundation presented $31,000 to continue research in neurological sciences under the direction of Dr. Elisha S. Gurdjian of the College of Medicine. The Receiving Hospital Corporation gave $25,000 to be added to the fund to defray salaries of individuals employed in departmental research activities at the College of Medicine.

MINNESOTA

Surgical Travel Fund.—The Regents of the University of Minnesota accepted in July, 1952, from the late Dr. Walter M. Boothby of the Mayo Clinic and Dr. William R. Lovelace, II, of the Lovelace Foundation, Albuquerque, New Mexico, a gift of $18,000, representing accumulated royalties from the manufacture of the Boothby-Lovelace oxygen mask. This fund was set up by Drs. Boothby and Lovelace as a surgical travel fellowship under the direction of the Department of Surgery at the University of Minnesota. The earned interest of the fund is being used to permit some of the Trainees of the Department of Surgery to visit other clinics and medical schools.

NEW JERSEY

Slide Seminar on Unusual Tumors.—The eighth annual slide seminar on unusual tumors, sponsored by the New Jersey Society of Pathologists and the New Jersey State Health Department, will be held December 6 at the Essex House, Newark, New Jersey at 2:00 p. m. Case histories and micro slides are being mailed to all members of the society. Dr. Arthur P. Stout of Columbia University College of Physicians and Surgeons, New York, will act as moderator. Dr. Jacob Churg of Teaneck, chairman of the program committee, and Elmer L. Shaffer, Ph.D., will represent the New Jersey State Department of Health. All interested physicians are invited to attend.

NEW YORK

Army Reserve Hospital Moves to New Headquarters.—The 307th General Hospital, a 1,000 bed U. S. Army Reserve Unit, outgrew the space and facilities at its training center on West 44th Street, New York City, and has moved to new headquarters on the St. John's University campus at Hillside, Jamaica. This unit, which is now at full strength, underwent its annual summer training period in August at Ft. Dix, New Jersey. Most of the commissioned and non-commissioned officers have had active service in either World War II or Korea and nearly all members of the hospital detachment are either high school or college graduates. Col. Gerald D. Dorman, M. C., New York City, a member of the House of Delegates of the American Medical Association, has been in command of the 307th General Hospital ever since it was activated in July, 1955.

Wadsworth Lecture.—The ninth Augustus B. Wadsworth Lecture is to be given at the Division of Laboratories and Research, New York State Department of Health, Albany, Nov. 20. Dr. Albert H. Coons, investigator for the American Heart Association and visiting professor of bacteriology and immunology, Harvard Medical School, Boston, will speak on "Stalking with Antibodies." The lectureship was established in 1950 by the staff of the Laboratories and the Council of the New York State Association of Public Health Laboratories.

New York City

Aaron Brown Lecture.—The third annual Aaron Brown lecture, sponsored by the Phi Delta Epsilon Fraternity, Beta XI Chapter, will be delivered February 14, 1959 at 11:00 a. m. at Georgetown University School of Medicine, Washington, D. C. Dr. Bernard J. Alpers, Philadelphia, will speak on "Compensating Mechanisms in Cerebral Blood Flow."

Personal.—Dr. Ammon Walter Hoover has been appointed regional medical officer of the Pennsylvania Railroad's New York region succeeding Dr. John D. Talbert, resigned.——Benjamin W. Zweifach, Ph.D., an investigator of the American Heart Association giving full time to research at New York University College of Medicine, has been promoted to full professor in the department of pathology.

Health Forums for the Public in Brooklyn.—The Brooklyn office of the New York City health department, the Brooklyn Academy of Arts and Sciences and the New York Journal American have joined the Kings County Medical Society in sponsoring a series of health talks to be given at the Brooklyn Academy of Music as follows:

Nov. 19, 1958—Diabetes
Dec. 3, 1958—Tuberculosis
Mar. 4, 1959—Dental Health
Apr. 1, 1959—Cancer
May 6, 1959—Nutrition

Lectures for the Laity.—The 24th series of Lectures for the Laity, presented by the New York Academy of Medicine, 2 East 103 St., began Nov. 5 with the Linsly R. Williams Memorial Lecture, "Fact, Fancy and Corruption in the Interpretation of Science to the Public," by Wallace F. Janssen of the U. S. Food and Drug Administration. The next lecture in this series will be Nov. 19, 8:30 p. m., by Paul F. Lazarsfeld, Ph.D., Columbia University College of Physicians and Surgeons, on "Paths and Roadblocks Between the Natural and the Social Sciences," and on Dec. 3, 8:30 p. m., Elmer Hutchisson, Ph.D., director of the American Institute of Physics, will discuss "Liberal Education in an Age of Science."

Medical Mobilization for Disaster.—A symposium on medical mobilization for disaster was held at the Kings County Hospital Center in Brooklyn Oct. 25, sponsored by the surgery department of the State University of New York Downstate Medical Center and the trauma service of the Kings County Hospital Center, and in cooperation with the New York State Department of Civil Defense. The speakers were Col. Joseph R. Shaeffer, of the Walter Reed Army Institute of Research, Washington, D. C., Dr. Roald N. Grant, professor of surgery, New York University College of Medicine, Dr. Robert H. Kennedy, director of surgery at the Beekman Downtown Hospital, and Dr. James M. Hershey, of the New York State Department of Health.

NORTH CAROLINA

New Biology Building at Duke.—The site for a new biology-forestry building at Duke University just south of the Physics Building has been cleared and construction is expected to begin this fall. The U. S. Public Health Service has approved a $234,500 grant toward the cost of this building, which is expected to cost a total of 3½ million dollars, and provide facilities for research work in physiology, cytology, serology, biochemistry, biophysics and nuclear chemistry. The zoology department, the botany department and the school of forestry each will occupy a separate wing of the building.

PENNSYLVANIA

Philadelphia

Foundation Grants in New Fields.—Four University of Pennsylvania medical scientists have been awarded grants totaling $245,382 by the March of Dimes of the National Foundation (formerly the National Foundation for Infantile Paralysis). The four scientists are Dr. Arthur B. DuBois, associate professor of physiology and pharmacology; Dr. William Dunbar, coordinator of the rehabilitation program at the University; William F. McLimans, Ph.D., associate professor of research medicine; Dr. Hilary Koprowski, director of the Wistar Institute. The first medical research grants to come to the Philadelphia area from the Foundation under its new policy of supporting work in fields other than poliomyelitis will be in the fields of virus research, tissue culture cell changes, scoliosis, and rehabilitation.

TEXAS

Medical Problems of Space Flight.—A symposium on the foregoing subject at Randolph Air Force Base, Texas, Oct. 28, was sponsored by the School of Aviation Medicine and the Bexar County Medical Society. Col. Paul A. Campbell, chief of the school's Space Medicine Division, surveyed recent research on factors affecting human performance and survival in space. Capt. Jerrold L. Wheaton's paper dealt with the effects of "Isolation and Sensory Deprivation" on flyers under conditions they will meet on flights beyond the earth's atmosphere. Lt. Col. George R. Steinkamp, chief, department of astroecology, discussed studies made by the school in "Closed Ecological Systems."

After dinner, the program continued with a paper on "The Zero Gravity State," by Capt. Willard R. Hawkins of the Space Medicine Division. Dr. Hubertus Strughold, advisor for research concluded the program with a look at the future of human flight in space. The program was arranged by Col. Hamilton B. Webb, chief, Aviation Medicine Division, and Dr. Billy B. Markette, of San Antonio, representing the county medical society. Presiding were Maj. Gen. Otis O. Benson Jr., commandant of the School of Aviation Medicine, and Dr. Charles W. Tennison, president of the Bexar County Medical Society.

UTAH

State Medical Election.—At the annual meeting of the Utah State Medical Association, Sept. 9-12, the following officers were elected: president, Dr. Ulrich R. Bryner, Salt Lake City; president-elect, Dr. I. Bruce McQuarrie, Ogden; honorary president, Dr. Arthur J. Murphy, Salt Lake City; secretary, Dr. J. Poulson Hunter, Salt Lake City; treasurer '60, Dr. Robert M. Dalrymple, Salt Lake City; executive secretary, Mr. Harold Bowman, Salt Lake City.

GENERAL

New Address of Science Foundation.—The National Science Foundation, an independent agency of the United States Government, announces that all offices are now centralized in one building at 1951 Constitution Avenue, Washington 25, D. C., Telephone, Sterling 3-2140.

Society News.—The American Board of Anesthesiology, at its annual meeting October 3, elected the following officers: president, Dr. Curtiss B. Hickcox, Hartford, Conn.; vice president, Dr. Frederick P. Haugen, Portland, Ore.; secretary-treasurer, Dr. Forrest E. Leffingwell, Pasadena, Calif.

Medical Clinics Election.—At the recent annual meeting of the American Association of Medical Clinics in San Francisco, Dr. Joseph W. St. Geme, of Los Angeles, was elected president; Dr. Russell V. Lee, Palo Alto, Calif., vice-president; and Dr. Joseph B. Davis, of Marion, Ind., secretary-treasurer. The next meeting of the association will be at the Blackstone Hotel, Chicago, Sept. 24-26, 1959.

F.B.I. Wants Help in Locating Cole and Conley.—The Federal Bureau of Investigation is trying to locate the following two persons who may apply for treatment at some physician's office:

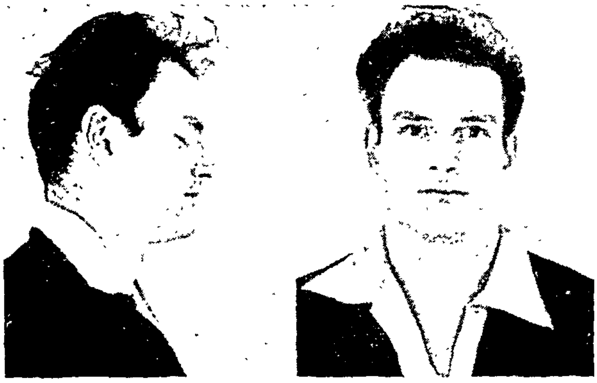

Fig. 1.—George Edward Cole.

George Edward Cole, alias George E. Cole, George Edward Puckett, George Edward Cole Puckett. Cole is alleged to have shot and killed a San Francisco police officer Dec. 30, 1956, during an attempted holdup of a tavern. Cole fled from California and a federal warrant for his arrest has been issued. This fugitive is armed and is considered extremely dangerous. Cole was born March 24, 1927, in Philadelphia. His height is 6 ft. 1 in.; weight 160 to 178 lb.; build, medium, hair, brown, receding; eyes, brown; complexion, medium; race, white; nationality, American; occupations, bus driver, truck driver, typist. He has a pit scar on outside corner of right eye, small cut scar on inside of left wrist, appendectomy scar, tattoo small heart and names "Mom" and "Dad" and letters "GP" or "SP" on left forearm; tattoo eight-point star on back of left hand; wears full upper denture.

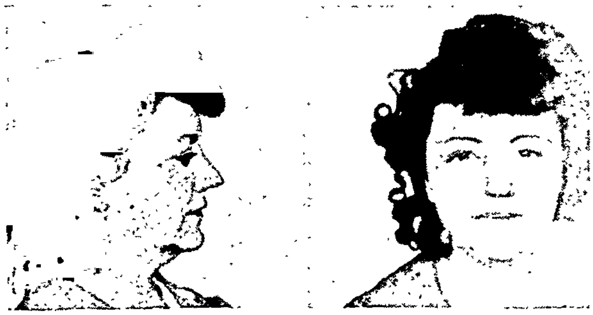

Fig. 2.—Yvonne Conley.

When Cole fled San Francisco it is believed he was accompanied by Yvonne Conley and it is possible this woman is still with him. Yvonne Conley has used the following aliases: Yvonne B. Blunt, Yvonne Broome, Lee Burke, Starr Burk, Yvonne Galipeau, Yvonne Hales, Mrs. V. Q. Hales, Yvonne Mason, Jean Noble, June Noble, and Lee Walker.

Conley has used drugs which in some states require a doctor's prescription. She has been treated for cirrhosis of the liver. She has used Empirin Compound, liver extract, vitamin B_{12}, Premarin, and Amesiec. She was born July 19, 1913, at St. Pierre, Manitoba, Canada. Her height is 4 ft. 11½ in.; weight, 140 lb.; build, heavy; hair, brown; eyes, brown; complexion, dark; race, white. She has a ½ in. cut scar on forehead between eyebrows, ½ in. cut scar under chin, scar on back of left hand, hysterectomy scar, numerous needle marks on hips; some upper teeth reportedly are missing. F.B.I. Number 1,055,332. The San Francisco Police Department, California, holds a warrant charging Conley as Yvonne Galipeau as an accessory to murder.

Any person having information that might assist in locating one or both of these persons is requested to immediately notify the Director of the FBI, Department of Justice, Washington 25, D.C., or the special agent in charge of the nearest FBI Division, the telephone number of which appears on the first page of local telephone directories.

Since Cole is considered extremely dangerous, no person should take any action which would place his or her life in jeopardy.

Grants to Aid Mental Health Workers.—The National Institute of Health, Washington, D. C., has granted $90,000 to the Southern Regional Education Board, 881 Peachtree Street, N. E., Atlanta 9, Georgia, for grants for in-service training of workers in mental institutions in southern states. These grants are available to anyone working on the staff of the mental hospital or training school, including administrative, professional and operational personnel. Persons interested may write to the above address in Atlanta.

Inter-Society Cytology Council.—When this group meets at the Hotel Statler, New York City, Nov. 13-15, the program will include panel discussions on cytology of disseminated cancer, in-situ bronchogenic carcinoma, and round-table discussions on cytology and pathology of early endometrial cancer, sessions on hormonal cytology, gynecologic cytology, cytology of irradiation, a symposium on the cell, medical motion pictures, and scientific and technical exhibits. Members and guests are invited to the annual banquet Thursday evening. Dress is optional. The president of the society is Dr. Emerson Day, New York City, and the president-elect is Dr. John R. McDonald, Rochester, Minn. Information may be obtained from the secretary, Dr. Paul F. Fletcher, 634 N. Grant Blvd., St. Louis 3.

Meeting of Gastroenterology Research Group.—The general subject for the meeting of the Gastroenterology Research Group in Chicago, October 31, was "Absorption of Water and Electrolytes from the

Gastrointestinal Tract." The panel moderated by Dr. Chas. A. M. Hogben, Washington, D. C. and the members of the panel, Eugene D. Grim, Ph.D., of the University of Minnesota; Dr. Isidore S. Edelman of the University of California Medical Center, San Francisco; Jack M. Ginsburg, Ph.D., of the University of Cincinnati College of Medicine; Drs. John F. Scholer of Palo Alto, California; Chas. F. Code, Mayo Clinic, Rochester; John T. Farrar of Cornell University Medical College, New York, and Donald W. Seldin of the University of Texas Southwestern Medical School, Dallas.

Interstate Postgraduate Medical Association.—The 43rd international meeting of the Interstate Postgraduate Medical Association will be at the Statler-Hilton Hotel, Cleveland, Ohio, November 10-13, under the presidency of Dr. Tom D. Spies, Birmingham, Alabama. In addition to a scientific program featuring distinguished speakers on various subjects, Mr. Charles F. Kettering, scientist, will address the annual dinner Wednesday evening on "An Inventor Looks at Science and Medicine." There will be exhibits, teaching films and a program of entertainment for the ladies. The registration fee is $10.00 except for physicians in the armed forces, residents and internes, graduate nurses, technicians and dieticians ($2.00). A complete program of this meeting may be obtained by writing to the Interstate Postgraduate Medical Association, Box 1109, Madison 1, Wis.

Cancer Seminar in Tampa, Florida.—The ninth biennial meeting of the Southeastern States Cancer Seminar will be at the Hillsboro Hotel, Tampa, Fla., Nov. 19-21, presented by the Hillsborough County Medical Association and sponsored by the Florida Division of the American Cancer Society and the Florida State Board of Health, in cooperation with the Florida Medical Association. In addition to panel discussions on various aspects of cancer, there will be individual presentations including among others the following guest speakers: Drs. Joseph P. Concannon, Jefferson Medical College of Philadelphia; August R. Crane, University of Pennsylvania School of Medicine, Philadelphia; Ruben Flocks, State University of Iowa College of Medicine, Iowa City; Simon Kramer, Jefferson Medical College of Philadelphia; Stanley L. Lane, Albert Einstein College College of Medicine of Yeshiva University, New York; Joseph V. Meigs, Harvard Medical School, Boston; James L. Pipkin, Baylor University Post-graduate School of Medicine, Houston, Texas; James D. Rives, Louisiana State University School of Medicine; Herbert E. Schmitz, Stritch School of Medicine of Loyola University, Chicago; Max M. Strumia, University of Pennsylvania Graduate School of Medicine, Philadelphia; and Kenneth W. Warren, of the Lahey Clinic, Boston.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Area	Oct. 11, 1958		Oct. 12 1957 Total
	Paralytic Type	Total Cases	
New England States

American College of Cardiology.—The seventh interim meeting of the American College of Cardiology will be at the Jung Hotel, New Orleans, La., Nov. 20-22. The presentations before the scientific session Thursday afternoon will be by the New Orleans group. Fireside conferences comprising five individual presentations will be held Thursday evening, 8:30 to 10 p. m. A symposium on "Diagnosis of Arterial Disease" will comprise the second scientific session Friday morning, and a symposium on "Medical Treatment of Arterial Disease" will be held Friday afternoon. On Saturday morning will be the symposium on "Surgical Treatment of

Peripheral Arterial Disease," and six scientific papers will be presented by members on Saturday afternoon. The program for the ladies includes a luncheon Thursday and then a tour of the famous French Quarter. After breakfast at Brennan's Friday morning, buses with guides will take the ladies on a tour of the city. There will be a banquet Friday evening (dress optional).

FOREIGN

Smallpox in Pakistan.—The government of Pakistan recently requested help from the World Health Organization in dealing with the worst smallpox epidemic Pakistan has experienced since that country was created in 1947. In complying, WHO shipped two million doses of smallpox vaccine to Pakistan. According to the September Chronical of the WHO, preliminary estimates indicate that in the first five months of 1958 there were more than 35,500 smallpox cases, with 15,800 deaths in Pakistan. In 1957 the number of cases of smallpox in this country was said to be almost 25,000.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral.* Phoenix, April 5-10. All applications already on file. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates in the South and Southwest, New Orleans, Feb. 3-6. Final date for filing application is Jan. 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application is Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application is March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application is March 1. *Examination in the Subspecialties. Gastroenterology.* Philadelphia, April 17-18. Final date for filing application is Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Part I.* Various parts of the United States and Canada, January 16. Candidates notified of their eligibility to participate in Part I must submit their case abstracts within thirty days of notification of eligibility. No candidate may take the written examination unless the case abstracts have been received in the office of the Secretary. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written,* qualifying test (Part I), Various Cities, Jan. 26. *Oral.* Philadelphia, June 3-6. Sec., Dr. Merrill J. King, 22 White St., Rockland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 21-23, 1959. Deadline for receipt of applications was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application is February. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pediatrics: *Oral.* New York, Dec. 5-7. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application is February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Boston, May 9-11. Final date for submitting case reports is Jan. 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Preventive Medicine: *Written. Public Health.* Regional, Apr. 9-11. *Occupational Medicine.* Chicago, Apr. 17-19. *Aviation Medicine.* Los Angeles, Apr. 24-26. Final date for filing application for all three examinations is Jan. 15. Sec., Dr. Tom F. Whayne, 3438 Walnut St., Philadelphia 4.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application is March. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: New York City, Dec. 15-16; New Orleans, Mar. 16-17. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 will be terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Regular Examination.* Washington, D. C., Dec. 8-11. Final date for filing application was July 1. *Special examination in Nuclear Medicine for those diplomates in Radiology or Therapeutic Radiology.* Washington, D. C., Dec. 6. Final date for filing application was Oct. 1. *Special Examination.* Cincinnati, Mar. 16-19, 1959. Final date for filing application is Nov. 1. Candidates completing training June 30, 1959 are not eligible for the Spring 1959 examinations. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: Written examinations (Part I) will be held at various centers in the United States, Canada, Hawaii, Puerto Rico, and certain military centers abroad on December 3. The date of the Fall examination in *Part I* has been changed from the last Wednesday of October as announced in its current Booklet of Information to December 3, 1958. Thereafter, examinations in Part I will be held once annually, on the first Wednesday of December. The closing date for filing applications was August 1. *Part II.* New York City, Dec. 15-16; Houston, Tex., Jan. 12-13; New Haven, Conn., Feb. 9-10; Durham, No. Car., March 9-10; San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Oral.* Los Angeles, April. Final date for filing application is Dec. 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

American Board of Urology: *Written Examination.* Twenty-five cities throughout the country, Dec. 5. The oral will be given in Chicago in February 1959. Sec., Dr. William Niles Wishard, Jr., 30 Westwood Road, Minneapolis 26.

DEATHS

Bliss, Rodney Waldo, Oklahoma City, Okla.; Rush Medical College, Chicago, 1904; professor of medicine emeritus and chairman of the department at the University of Nebraska College of Medicine, Omaha; member of the Nebraska State Medical Association; an associate member of the American Medical Association; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served on the staffs of the Nebraska Methodist and University of Nebraska hospitals; died Sept. 5, aged 80.

Boyden, Guy Lee Ⓜ Portland, Ore.; born in Brookings County, S. D., Feb. 17, 1885; Northwestern University Medical School, Chicago, 1911; on July 1, 1911 entered the Mayo Clinic, Rochester, Minn., where he served an internship and residency at St. Mary's Hospital; from 1913 to 1921 practiced medicine in Pendleton, Ore.; veteran of World War I; clinical professor and head, department of otology, rhinology and laryngology, University of Oregon Medical School; was the guest of honor at a meeting in 1958 in San Francisco of the Section on Laryngology, Otology and Rhinology of the American Medical Association, of which he was vice chairman in 1954-1955; past-president of the Oregon Academy of Ophthalmology and Otolaryngology and the Pacific Coast Ophthalmology and Otolaryngology Society; member of the American Laryngological, Rhinological and Otological Society, of which he was at one time vice-president and western chairman; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; associated with the Multnomah Hospital, Emanuel Hospital and St. Vincent's Hospital and Doernbecker Memorial Hospital for Children; in 1955 received an honorary doctor of science degree from South Dakota State College of Agriculture and Mechanic Arts, Brookings; died Sept. 9, aged 73.

Brown, Charles W., Ⓜ St. Louis; St. Louis College of Physicians and Surgeons, 1890; formerly practiced in Caruthersville, Mo.; died Sept. 4, aged 93.

Buck, Samuel Bernice, Anderson, Mo.; University of Maryland School of Medicine, Baltimore, 1904; died in the Veterans Administration Hospital, Fayetteville, Ark., Aug. 28, aged 78.

Carnathan, William George Ⓜ Dallas, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1921; specialist certified by the American Board of Psychiatry and Neurology; service member of the American Medical Association; member of the American Psychiatric Association; at one time on the faculty of his alma mater and Baylor University College of Medicine; from 1942 to 1946 associated with the Texas State Guard; on the staff of the Veterans Administration; died in the Dallas Medical and Surgical Clinic July 8, aged 67, of myocardial infarction.

Cates, Albert, Oklahoma City, Okla.; Memphis (Tenn.) Hospital Medical College, 1906; an associate member of the American Medical Association; served as county health superintendent of public health; died Sept. 4, aged 78, of hypertension and cerebrovascular disease.

Colleran, John Patrick, South Deerfield, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1928; member of the Massachusetts Medical Society; school physician in South Deerfield; on the staffs of the Farren Memorial Hospital in Montague City, and Franklin County Public Hospital in Greenfield; died Sept. 8, aged 55, of cancer of the pancreas.

Cook, Byron Llewellyn Ⓜ Minden, La.; Louisiana State University School of Medicine, New Orleans, 1938; member of the American Academy of General Practice; past-president of the Fourth District Medical Society; veteran of World War II; died in the Schumpert Sanitarium, Shreveport, Aug. 31, aged 44, of disseminated lupus erythematosus.

Cosgrove, Edgar Francis Ⓜ Pittsburgh; University of Pittsburgh School of Medicine, 1936; assistant professor of medicine at his alma mater; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; veteran of World War II; past-president of the Western Pennsylvania Heart Association; associated with Woman's Hospital and the Presbyterian Hospital, where he died Sept. 3, aged 49.

Cowles, Robert Sebastian Ⓜ Greeneville, Tenn.; University of Nashville Medical Department, 1910; past-president of the Greene County Medical Society; for many years county health officer; died Aug. 27, aged 66.

Criss, Ralph J., Coffeeville, Miss; University of Nashville (Tenn.) Medical Department, 1904; died Sept. 11, aged 82.

Davis, James Ethelbert Ⓜ Dexter, Mich.; born in Woodstock, Ont., Oct. 3, 1870; Detroit College of Medicine, 1896; also a graduate in pharmacy; for many years professor of pathology at his alma mater, now known as the Wayne University College of Medicine; served as director of the department of pathology at the University of Detroit Dental

---

Ⓜ Indicates Member of the American Medical Association.

Department, and extramural lecturer in pathology at the University of Michigan Graduate Medical School; originated the Beaumont Lectureship Foundation; past-president and for many years trustee of the Wayne County Medical Society; past-president of the Alumni Association of the Detroit College of Medicine and Surgery; for many years secretary of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons; served on the staffs of the Providence, St. Mary's, and Receiving hospitals; died in the Woodstock (Ont.) General Hospital Aug. 16, aged 87, of coronary thrombosis.

Deak, Alexander Paul Ⓜ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1924; died in the Presbyterian Hospital Sept. 2, aged 60.

Decatur, Edwin Forrest Ⓜ Kingston, N. H.; Tufts College Medical School, Boston, 1939; member of the American Society of Anesthesiologists; chief of the anesthesiology department at Exeter (N. H.) Hospital, where he was past-president of the medical staff, and where he died Aug. 29, aged 45.

De Pree, John Nelson Warren Ⓜ Palouse, Wash.; Rush Medical College, Chicago, 1939; member of the American Academy of General Practice; on the staff of the Gritman Memorial Hospital in Moscow; served as president of Whitman County Medical Society; died in Spokane Sept. 4, aged 49.

Dias, Joseph Lawrence, Tampa, Fla.; Columbia University College of Physicians and Surgeons, New York City, 1903; an associate member of the American Medical Association; at one time practiced in Newark, N. J., where he was on the staff of Hospital of St. Barnabas; member of the Medical Society of New Jersey; formerly on the staff of the Veterans Administration Hospital in Lake City; died in St. Joseph's Hospital Sept. 3, aged 77, of cerebrovascular thrombosis and cancer of the pancreas.

Dixon, Robert Emmett Ⓜ Alberta, Ala.; University of Alabama School of Medicine, Mobile, 1917; died Aug. 22, aged 66, of leukemia.

Downes, John Raymond Ⓜ Newark, Del.; University of Maryland School of Medicine, Baltimore, 1904; formerly health officer of Queen Anne County; served as city councilman; deputy state health officer for rural New Castle County from 1931 to 1949 when he retired; veteran of World War I; died in the Veterans Administration Hospital, Wilmington, Sept. 4, aged 79.

Doyle, Francis Joseph, Fort Lauderdale, Fla.; Long Island College Hospital, Brooklyn, 1902; died July 18, aged 80, of congestive arteriosclerotic heart disease.

Durburg, John Russell Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1934; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; served on the faculty of his alma mater; veteran of World War II; member of the staff of St. Joseph's Hospital; died in Cape May, N. J., Sept. 15, aged 48.

Everist, Guy Vernon Ⓜ San Diego, Calif.; St. Louis University School of Medicine, 1935; veteran of World War II; served on the staffs of various Veterans Administration hospitals; found dead in his car Sept. 3, aged 50.

Foot, Nathan Chandler, New York City; born in New York City July 27, 1881; Columbia University College of Physicians and Surgeons, New York City, 1907; emeritus professor of surgical pathology at Cornell University Medical College, where he was professor of surgical pathology from 1932 to 1948, and where he did research in cancer detection in the department of pathology; from 1912 to 1919 assistant instructor and instructor of pathology at Harvard Medical School, Boston, where he became instructor of comparative pathology, serving until 1922; assistant professor, associate professor, and professor of pathology at University of Cincinnati College of Medicine from 1922 to 1932; served as research consultant in pathology at the Armed Forces Institute in Washington, D. C.; an associate member of the American Medical Association; fellow of the College of American Pathologists; member and past-president of the American Association of Pathologists and Bacteriologists; member of the American Society of Experimental Pathology, New York Academy of Medicine, New York Pathological Society, of which he was past-president, Harvey Society, American Association for the Advancement of Science, Phi Rho Sigma, Sigma Xi, and Alpha Omega Alpha; corresponding member of the Pathological Society of Argentina; member of the Intersociety Cytology Council; past-president of the American Board of Pathology; served as president of the New York Physicians Art Club; surgical pathologist at the New York Hospital from 1932 to 1948 when he became consultant; author of two textbooks, "Pathology in Surgery" and "Identification of Tumors"; died in the New Rochelle (N. Y.) Hospital Sept. 4, aged 77.

Freeman, Rowland Godfrey Jr., Ⓜ Boston; Columbia University College of Physicians and Surgeons, New York City, 1921; member of the American Psychiatric Association and the Association for Research in Nervous and Mental Disease; formerly on the faculty of Tufts College Medical School; in 1937 appointed assistant psychiatrist of the Judge Baker Guidance Center in Boston; veteran of World War II; formerly clinical director at Blytheville in Greenwich, Conn.; died in the Peter Bent Brigham Hospital, Boston, July 23, aged 62, of pulmonary embolism.

Gilbert, Edwin Carpenter, Longmeadow, Mass.; Yale University School of Medicine, New Haven, Conn., 1906; veteran of World War I; for many years trustee of the Belchertown (Mass.) State School; formerly practiced in Springfield, where he served on the staff of the Springfield Hospital, and past-president of the Chamber of Commerce and Rotary Club; died in the Brattleboro Retreat, Brattleboro, Vt., Aug. 23, aged 76, of bronchopneumonia and cerebral arteriosclerosis.

Gilmer, Roy Jones, New Haven, Conn.; Meharry Medical College, Nashville, Tenn., 1942; veteran of World War II; physician for the local welfare department; on the staffs of the Grace-New Haven Community Hospital and the Hospital of Raphael, where he died Aug. 30, aged 42, of coronary thrombosis.

Girvin, Richard Bates Ⓜ Minneapolis; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1908; member of the Aero Medical Association; veteran of World War I; in 1940 appointed medical examiner for the Civil Aeronautics Authority; on the staffs of St. Barnabas and St. Andrews hospitals; died in the Barnes Hospital, St. Louis, Aug. 7, aged 74, of emphysema.

Gregg, Ulysses Sherman, Kalamazoo, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909; served on the staff of the Kalamazoo State Hospital; honorary member of the medical staff, Bronson Methodist Hospital, where he died Aug. 27, aged 78, of cerebral thrombosis.

Hardie, Julian Carter, Salt Lake City; University of Pennsylvania School of Medicine, Philadelphia, 1911; retired in 1947 as county physician; physician and surgeon for the Utah Copper Company and U. S. Fuel Company in Garfield and Hiawatha, Utah; died Aug. 17, aged 83, of bronchopneumonia.

Haynsworth, Custis Hall Ⓜ Greenville, S. C.; Medical College of South Carolina, Charleston, 1941; interned at the Central Dispensary and Emergency Hospital in Washington, D. C.; served a residency at the Shriners Hospital for Crippled Children in Greenville, Roper Hospital in Charleston, and the Hospital for Special Surgery in New York City; chief of orthopedic service at the Greenville General Hospital; died Aug. 15, aged 43.

Helland, John William Ⓜ Spring Grove, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1905; died in La Crosse (Wis.) Lutheran Hospital Aug. 28, aged 80.

Hochwald, Adolf, Ray Brook, N. Y.; born in Tesin, Czechoslovakia, Sept. 5, 1906; Masarykova Universita Fakulta Lekarska, Brno, Czechoslovakia, 1930; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists, Medical Society of the State of New York, American Association for the Advancement of Science, and the Cleveland Society of Pathologists; fellow of the College of American Pathologists; instructor in pathology at the Woman's Medical College of Pennsylvania in Philadelphia, 1943-1944; senior instructor in pathology at Western Reserve University School of Medicine in Cleveland, from 1948 to 1951; served as assistant professor of pathology at the New York University College of Medicine; formerly on the staffs of the Mount Sinai Hospital in Cleveland and University Hospital (New York University–Bellevue Medical Center) in New York City; since 1954 associate pathologist at the Ray Brook State Tuberculosis Hospital, where he died Aug. 31, aged 51, of myocardial infarction and essential hypertension.

Johnson, Jesse Brealand Ⓜ Galveston, Texas; University of Texas School of Medicine, Galveston, 1913; professor of radiology at his alma mater; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America, and the American College of Radiology; past-president of the Texas Radiological Society, and the Galveston County Medical Society; served on the staff of the John Sealy Hospital; died Aug. 18, aged 68, of cancer of the larynx.

Johnson, John Franklin Ⓜ Chattanooga, Tenn.; Vanderbilt University School of Medicine, Nashville, 1919; member of the American Academy of General Practice; past-president of the General Practitioners of Chattanooga; died Aug. 31, aged 66.

Joyce, Francis William Ⓜ Pittsburgh; George Washington University School of Medicine, Washington, D. C., 1918; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; president of the medical staff and chief pathologist, St. John's Hospital, where he was a member of the staff for many years; died Aug. 21, aged 67, of coronary occlusion.

Kaplan, Isador, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1922; died Aug. 31, aged 65.

Klein, Sidney Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1919; assistant clinical professor of psychiatry at New York University College of Medicine and New York University Post-Graduate Medical School; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychoanalytic Association and the American Psychiatric Association; associated with Hillside Hospital in Glenn Oaks, University Hospital (New York University-Bellevue Medical Center); died July 29, aged 62, of coronary thrombosis.

Kyle, Bernard Hewitt Ⓢ Lynchburg, Va.; born in Buffalo Springs, April 17, 1887; Medical College of Virginia, Richmond, 1911; member of the American Academy of Orthopaedic Surgeons; specialist certified by the American Board of Orthopaedic Surgery; past-president of the Lynchburg Academy of Medicine; veteran of World War I and received commendations from this country and its Allies; a member of the Procurement and Assignment Service for Physicians in World War II and for two years was on the Military Induction Board in Roanoke; designated examiner for the U. S. Employees' Compensation Commission; associated with Marshall Lodge Memorial Hospital, Virginia Baptist Hospital, and Lynchburg General Hospital; orthopedic surgeon for the Norfolk and Western Railway; died Aug. 22, aged 71.

Lacy, Justin Ernest, Knoxville, Tenn.; Vanderbilt University School of Medicine, Nashville, Tenn., 1901; an associate member of the American Medical Association; served on the staffs of the Veterans Administration hospitals in various cities; veteran of World War I; died in Washington, D. C., Aug. 28, aged 79, of cancer of the mouth.

McCartney, James Shearer Ⓢ Minneapolis; born in Tarentum, Pa., July 21, 1893; Johns Hopkins University School of Medicine, Philadelphia, 1917; professor of pathology at the University of Minnesota Medical School and the University of Minnesota Graduate School; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists and the College of American Pathologists; veteran of World War I; served as president of the state board of medical examiners in the basic sciences; consultant in pathology at Abbott Hospital, Asbury Hospital, and the Northwestern Hospital, where he died Aug. 30, aged 65, of cerebral hemorrhage.

McLeod, Alexander Ⓢ Glenallen, Va.; Baltimore Medical College, 1913; veteran of World War I; died in Richmond Sept. 2, aged 67, of cancer.

Mammen, Goeke Henry Ⓢ Chicago; Rush Medical College, Chicago, 1894; fellow the American College of Surgeons; associated with the Lutheran Deaconess Hospital, where he died Aug. 30, aged 86, of uremia and arteriosclerosis.

Mason, Virgil Andrew Ⓢ East Orange, N. J.; Cornell University Medical College, New York City, 1933; certified by the National Board of Medical Examiners; fellow of the American College of Surgeons; associated with the Orange Memorial Hospital, where he died Aug. 21, aged 52, of bronchiogenic cancer with metastases.

Mechling, George Seanor Ⓢ Jackson, La.; born in Newkirk, Okla., Dec. 10, 1905; University of Oklahoma School of Medicine, Oklahoma City, 1932; formerly on the faculty of his alma mater; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthesiologists; formerly associated with the Central State Griffin Memorial Hospital and Norman Municipal Hospital in Norman, Okla.; served on the staff of the University Hospitals in Oklahoma City; on the staff of the East Louisiana State Hospital; died in the Ochsner Foundation Hospital, New Orleans, Aug. 22, aged 52, of cirrhosis of the liver.

Merrill, Ralph Edward Ⓢ Glendale, Calif.; Harvard Medical School, Boston, 1920; member of the American Academy of General Practice; on the staffs of St. Joseph's Hospital in Burbank, Glendale Hospital and Sanitarium, Glendale Memorial Hospital, and Behrens Memorial Hospital; died in the Glendale Hospital and Sanitarium Sept. 2, aged 63.

Morris, Hurston H., Portsmouth, Ohio; Marquette University School of Medicine, Milwaukee, 1926; died Aug. 26, aged 62.

Munch, Louise Lucy Ⓢ Chicago; Northwestern University Woman's Medical School, Chicago, 1901; died in St. George Hospital Sept. 4, aged 91, of chronic myocarditis and arteriosclerosis.

Munoz, Roque Narciso Alfonzo Ⓢ Chicago; Chicago Medical School, 1921; veteran of World War I; died in St. Anne's Hospital Sept. 9, aged 65, of acute coronary insufficiency with myocardial infarction.

Murphy, Simon William, Kenosha, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1909; veteran of World War I; died in St. Catherine's Hospital Aug. 31, aged 79.

Myer, Edward Herman, Mahwah, N. J.; Maryland Medical College, Baltimore, 1910; Baltimore Medical College, 1912; died Aug. 22, aged 70.

Osorio, Vasco Eric Monteiro Ⓢ Piedmont, Calif.; University of Louisville (Ky.) Medical Department, 1916; fellow of the American College of Surgeons; veteran of World War I; served with the Army of Occupation in 1919; formerly associated with Queen's, Children's, St. Francis, and Kapiolani hospitals in Honolulu, Hawaii; died Aug. 29, aged 71, of pulmonary embolism.

Pellegrini, Pietro, New York City; Regia Università deglia Studi di Parma. Facolta di Medicina e Chirurgia, Italy, 1896; an associate member of the American Medical Association; associated with Columbus and Italian hospitals and the City Department of Correction; died in Miami, Fla., Aug. 22, aged 87, of acute bronchitis and arteriosclerotic heart disease.

Potter, Marjory Janette Macpherson, La Mesa, Calif.; University of Buffalo School of Medicine, 1897; an associate member of the American Medical Association; died Aug. 16, aged 87, of coronary infarction and cerebral hemorrhage.

FOREIGN LETTERS

BRAZIL

Giardiasis.—Giardiasis is commonly treated with quinacrine, but often this drug produces undesirable side-effects. Rodrigues and Rocha e Silva (*Jornal de Pediatria,* vol. 23, July, 1958) treated 40 children who had this disease with chlorquinaldol. They gave 20 mg. per kilogram of body weight daily for 10 days. If the stools remained positive, they gave a second course using double this dosage. The feces were examined 10 and 20 days after the drug was discontinued. Negative stools were obtained in 29 or 72.5%. There was no intolerance of the drug, even with the larger dose. The authors concluded that the drug should be tried in those patients who showed an intolerance to quinacrine, which cures 90 to 98%.

Biliary Cancer.—Dr. Fernando Paulino and coworkers observed 28 patients (20 women and 8 men) with primary cancer of the biliary tract in the Casa de Saude São Miguel, Rio de Janeiro. The oldest patient was 74 and the youngest 32 (average 54). The tumor was localized in the gallbladder in 18, in the common bile duct in 6, and in Vater's ampulla in 4. Gallstones were found in 18. Microscopy revealed 25 adenocarcinomas, 1 squamous cell carcinoma, 1 scirrhous carcinoma, and 1 adenoacanthoma. Patients who had had gallstones for many years frequently noticed that the character of the pain changed from typical biliary colic to a constant pain in the right upper abdominal quadrant. According to the authors, this was due to neoplastic invasion of the nerves of the hepatic hilus. The results of surgical treatment were disappointing when the tumor was localized in the gallbladder and common duct. In four tumors of Vater's ampulla, duodenopancreatectomy was performed, twice with hope of cure (one patient was still alive two and one-half years after the operation, and the other died with metastases one year and 10 months after operation). Local excision of the ampulla was made in two patients over 70 years old; one was relieved of symptoms for two years. The authors recommend that in all patients with cancer of the biliary tract resection be attempted.

COLOMBIA

First Graduates of New Medical School.—In July the medical school of the Universidad del Valle at Cali held its first graduation. The school, opened in October, 1951, with 60 first-year students as an experiment in medical education, has had a short but important influence on the development of teaching, especially in basic sciences. The new school has been aided by the Kellogg Foundation which financed training in the United States for 13 members of its faculty and gave funds for the biochemical and pathological laboratories. Equipment for the public health and preventive medicine department and the library and training expenses for eight other faculty members were provided by the Rockefeller Foundation. From 1956 a Tulane-Colombia Medical Education Program has functioned under the guidance of Dr. E. C. Faust. The principal objectives of this program in Colombia are (1) cooperation in the planning and revision of the medical courses in undergraduate instruction, including the premedical and clinical years of study, so that future graduates of medical schools will have better training for the practice of medicine, (2) discovery of promising young men interested in teaching medical subjects and recommendation for their graduate training in Tulane University and other institutions, and (3) stimulation of medical research. To implement this program, in addition to a field coordinator, three or four specialists are sent each year from Tulane to work with the seven medical schools of Colombia for periods of three months. Another important contribution of the Valle medical school to the improvement of medical practice in Colombia was the organization of the first seminar on medical education in 1955.

Medical Education.—At the request of Dr. Eduardo Cortés-Mendoza, Dean of the medical school of the National University; Dr. Vernon B. Link, Chief of the Health, Welfare, and Housing Division, United States Operations Mission to Colombia; and Dr. E. C. Faust, a four weeks visit to the Medical school at Bogotá was made by Dr. B. G. Horning in July. His report emphasized organization and administration rather than teaching methods and techniques. The most important suggestions were that (1) the medical school be reorganized into 10 major departments, each representing a broad area of medical education, and that the chairman of each be given a full-time contract, (2) the Hospital San Juan de Dios be reorganized, each department rep-

resenting a broad area of medical education, (3) membership of the school council include the dean, the chairmen of the major departments, and two or more members elected to represent the faculty at large, (4) the deanship be made a full-time position with an adequate salary and secure tenure of office, (5) the dean and council make a more extensive and effective use of committees in the administration of the school, (6) the contest method in the selection and promotion of faculty staff members be discontinued, (7) the preliminary selection of teachers be made by a special committee appointed by the dean with the approval of the council searching the entire nation for the most suitable candidates, (8) the positions of professor and assistant professor be considered permanent until retirement, provided the holders continue to demonstrate growth and ability in their field, (9) the school continue to send brilliant young faculty members abroad for graduate study, especially in basic sciences, and older faculty members for short periods of orientation, (10) each department develop a nucleus of qualified staff members, including the chairmen, (11) adequate salaries be provided for the full-time staff members, (12) the government and the university increase the budget of the medical school, (13) the Junta de Beneficencia hire a well-trained hospital administrator to supervise all of the hospitals administered by it, (14) the Beneficencia de Cundinamarca provide more material help to medical education through the hospitals which it owns, (15) the chief librarian with the help of the library committee develop a plan for assisting medical students to purchase text books, (16) the curriculum be reorganized so that one year would be devoted to premedical studies, five years to medical education, and one year to a supervised internship, (17) "blocks of time" of several hours duration on successive days be allocated to certain of the preclinical subjects so that they may be completed in a shorter period of time, (18) the "block system" featuring the clinical clerkship and bedside teaching be adopted by the clinical departments as soon as possible, (19) less emphasis be placed on lectures and more on group teaching and laboratory work in the preclinical fields and on bedside teaching and the use of the library in the clinical fields, (20) the major emphasis of the curriculum be to provide students with the knowledge and skills necessary for private practice and first level public health positions and as a basis for specialization, (21) preventive medicine and public health be integrated with the curriculum as a whole and the curriculum committee study the amount of time allocated to each basic medical science subject in relation to its importance, (22) a strong department and section of preventive medicine and public health be developed, with adequate staff and facilities, including a modern health center, and a well-developed field area be provided, and (23) graduate medical education programs be developed in the basic sciences and in the clinical fields continuing opportunities for medical education be provided for practicing physicians.

INDIA

Corticosteroids in Tuberculous Meningitis.—K. J. Vyas (*Indian Practitioner* 11:8 [Aug.] 1958) treated 42 children who had tuberculous meningitis with corticosteroids. Their ages ranged from less than 6 months to just over 5 years. They got 5 mg. of prednisolone by mouth, q.i.d., for one week, followed by 5 mg., b.i.d., for one week, and then 2.5 mg., b.i.d., for another week. In severely ill and moribund patients treatment was initiated by giving cortisone intramuscularly for two to four days followed by prednisolone by mouth. All received simultaneously 0.5 Gm. of streptomycin and 150 mg. of isoniazid daily, irrespective of age and weight, for two months. These doses were later reduced for very young children. Streptomycin therapy was continued for another two months on alternate days and then every fourth day for a further period of two months. Isoniazid therapy was continued for one year.

On this treatment 30 were cured, 8 died, 1 was relieved, and 3 were unrelieved. Of the eight that died, one was 6 months of age, five were between 1 and 2 years old, and two were 4 years old. All but one was admitted in an unconscious or moribund condition. The patient classified as relieved was discharged after two months in the hospital and was much better clinically, conscious, and without neurological defects. Early diagnosis and early institution of treatment are important, but the younger the patient, the worse the prognosis. The results with the use of the hormone were dramatic, some children regaining consciousness in a few days. Most became afebrile promptly and remained so even after discontinuation of the hormone therapy. In a previous series of patients with tuberculous meningitis on whom corticosteroids were not used, 50% died. Thus, the use of corticosteroids definitely improved the prognosis of these patients.

Tropical Eosinophilia.—K. V. Rac treated 40 patients who had tropical eosinophilia with diethyl carbamazine (*Antiseptic* 55:8 [Aug.] 1958). The age of these patients ranged from 4 to 57 years, most of them being in the second, third, and fourth decade. The daily dosage of the drug was 10 to 12.5 mg. per kilogram of body weight and was administered in three divided doses for 10 days. In children treatment had to be continued for about 15 days to get the same result as in adults. Symptomatic relief was noticed in all but two patients within two days of starting the treatment.

The eosinophil count showed an almost immediate drop, while the lungs were clear of moist or dry rales as early as the third day. No serious toxic effects were met with, only seven complaining of such side-effects as general weakness, giddiness, diarrhea, and rash. The results on the whole were good in 31. In eight recurrence of asthmatic attacks occurred, and in five there was a concomitant rise in the eosinophil count. In three, although the eosinophil count had come down to normal, the symptoms persisted. Roentgenograms of the chest of some were made, and the lungs were seen to have cleared at the end of treatment, when the eosinophil count had also reached normal levels. The most striking features in therapy with this drug were the precipitous fall in eosinophil count immediately after treatment and early symptomatic relief with almost simultaneous clearance of lung signs. Arsenic used in the treatment of tropical eosinophilia also leads to an immediate fall in the eosinophil count, but the symptomatic relief is neither so marked nor so prompt.

Intussusception.—W. Singh and co-workers reported a series of six patients with tumors of the intestine causing intussusception (*Indian J. Surg.* 20:3 [June] 1958). Benign tumors of the intestine are uncommon and are rarely diagnosed clinically. Intussusception is the most common type of obstruction caused by such tumors. Three of these tumors were hemangiomas and three were fibromas. Two of the hemangiomas were in the small intestine, and the third was in the cecum. One was a single polypoid cavernous hemangioma, and the others were capillary hemangiomas of the small intestine and cecum. The remaining three were fibromas of the small intestine—one with myxomatous degeneration and another with a hyaline change. Five of the six were intraluminal. Three patients had a history of subacute obstruction going on to acute obstruction. The other three had signs and symptoms of acute intestinal obstruction of short duration. A history of previous pain and constipation lasting two months to six years was present in the three with fibroma, one of whom had pigmentation of the skin and subcutaneous neurofibromas. On exploration, intussusception of the ileoileal type was found in four and of the ileocolic type in two. Roentgenograms of four showed dilated coils of small intestine in one and a filling defect or complete obstruction in the others. The appearance was suggestive of intussusception in only two. The authors emphasized the importance of keeping in mind the possibility of finding a benign neoplasm of the small intestine in patients with obstruction, that intussusception is not so uncommon in adults as is usually believed, and that most of the times it is due to a benign tumor.

Pleurisy with Effusion.—P. N. Laha (*J. Indian M. A.* 31:5 [Sept. 1] 1958) studied a series of 25 patients who had pleurisy with effusion on one side to determine the intrapleural pressure changes on the affected side. The site chosen for measuring the intrapleural pressure was the second intercostal space of the affected side along the midclavicular line, which was above the level of the fluid in all but three patients. On the basis of the findings the patients were divided into five groups. The first included seven whose intrapleural pressure was within the normal range during inspiration and expiration and with regard to mean pressure. This was the first stage of effusion from the point of view of intrapleural pressure. The second group included five whose pressure could be recorded only during inspiration but was within the normal range. If the disease did not stop or improve at this second stage, the third stage set in with further effusion. The normal intrapleural pressure in this stage was modified in such a way as to maintain a negative intrapleural pressure during inspiration but produced a positive pressure during expiration and a mean intrapleural pressure of 0 cm. of water.

The fourth group included three patients in whom the effusion covered the entire pleural cavity. The intrapleural pressure could be recorded only during inspiration and was gradually becoming increasingly positive. The pressure reading during the phase of inspiration was not the correct measure of intrapleural pressure which could not be recorded due to lack of free pleural space. The fifth group included five patients in whom, in spite of the presence of free fluid in the pleural cavity, the intrapleural pressure could not be recorded in either phase of respiration due to obliteration of the pleural cavity above the level of the fluid. The duration of illness, level of the fluid in the pleural cavity, the position of the trachea, and the apex beat did not seem to be correlated with the findings of intrapleural pressure. The factor governing the changes in intrapleural pressure was the amount of fluid collected in the pleural cavity and the consequent collapse of the lung due to its elasticity. A measure of the elasticity of the lung of the affected side was reflected in the intrapleural pressure.

JAPAN

Gumma Fever.—In Gumma Prefecture where a recent typhoon caused severe damage, 1,000 persons were laid low with what appeared to be a new virus infection. The victims were stricken with fever of about 100 F (38 C), acute pharyngitis and conjunctivitis, and diarrhea. Children were first to fall sick, but the disease spread to adults later. The preventive measures advocated include ventilation of dwellings, especially sleeping quarters, and avoidance of gatherings. In Tokyo and Kyoto large numbers of school children are sick with symptoms strikingly similar to those of Gumma fever. Some health authorities believe this might be a new type of influenza.

Dental Caries.—Along with the census taking of a year ago government dentists made a dental survey of representative populations numbering 30,878 men, women, and children of all classes from various geographical areas and found that 85% of those examined had dental caries. Many were badly in need of dentures. Women with caries outnumbered men by 2%. The incidence in infants and preschool children was high: 17% in one-year-olds; 57% in 2-year-olds; and 80% in 3-year-olds. Among the adults, those requiring major and minor dental treatment exceeded 44%.

SWEDEN

Diagnosis of Silicosis.—Dr. L. Norviit (*Svenska läkartidningen,* July 25, 1958) examined scalene lymph nodes obtained by biopsy from 21 miners whose work might have provoked silicosis. All had been working for many years in an atmosphere of stone dust, and all but one showed radiologically demonstrable changes in the lungs. Before the biopsy, silicosis alone had been diagnosed in eight, silicosis plus tuberculosis in nine, sarcoidosis in one, sarcoidosis plus tuberculosis in one, tuberculosis alone in one, and nothing pathological in one. The biopsy revealed nothing abnormal in eight, sarcoidosis in one, silicosis alone in six, silicosis plus tuberculosis in four, and tuberculosis alone in two. Though biopsy is useful in demonstrating morbid changes in deep-seated lymph glands connected with the lungs, negative findings do not necessarily rule out silicosis.

Guinea Pig Versus Culture Tests for Tubercle Bacilli.—Dr. P. N. Oscarsson, (*Nordisk medicin,* Aug. 21, 1958) studied 3,728 tests carried out between 1950 and 1956 with a view to comparing the effectiveness of the guinea pig inoculation and culture tests for tubercle bacilli. He found that the former gave fewer positive results, the difference being statistically significant with respect to both sputum and gastric washing. With other material such as urine and exudates, the figures were too small to justify any conclusion. The divergencies between the two were most noticeable when only a few bacilli were demonstrable. It must be admitted that neither direct microscopy nor the culture test throws light on the pathogenicity of the germs found, so they may fail to distinguish between tubercle bacilli and nonpathogenic mycobacteria. Oscarsson concluded that the guinea pig test may prove of value as a supplement to culture in certain cases, but for routine examinations the culture test comes first.

Induced Abortions.—With the revision of Sweden's abortion law in 1946 there has been a rising tide of legally induced abortions. In 1951 there were 57 legal abortions per 1,000 live births. Dr. Per Arén studied the events of the past decade insofar as they threw light on what happened to the women involved (*Acta obstetrica et gynecologica scandinavica,* Supplement, 1958). The report deals with the records of 248 women who underwent legal abortion and subsequently again became pregnant, accounting for a total of 389 pregnancies; 100 women who had undergone a legally induced abortion and had subsequently achieved a pregnancy which went to term were selected at random and interviewed. Eighty-four said that, had legal abortion been refused them, they would have let their pregnancies go to term. In none had the subsequent pregnancy and confinement resulted in any threat to their health or working capacity. Another 197 women for whom the legal induction of abortion had been authorized but, for some reason or other, not actually accomplished were interviewed. Subsequent events showed that in 89% the failure to exploit the permission for an induced abortion was fortunate. The author urges a critical revision of the attitude of the community to the interruption of pregnancy on social indications.

Cortisone Treatment of Rheumatism.—The Swedish Ministry of Pensions sends many of its rheumatic patients to a hospital where about 1,400, chiefly suffering from rheumatoid arthritis, were treated in 1956 and 1957. Among them were 323 who had been treated with various forms of cortisone during periods ranging from a few weeks to four years before admission to this hospital. These patients were the subject of a statistical analysis by Dr. F. Bohman (*Nordisk medicin,* Sept. 18, 1958). In 132 there was improvement under cortisone therapy, with a relapse as soon as it was discontinued. In 88 no effect from the drug was observed. In 39 the disease became worse with use of it. In most of these cases cortisone had been given for a prolonged period, with improvement at first followed by aggravation of the symptoms in spite of continuation of the drug. In 41 there had been improvement which was maintained for weeks or months after it was discontinued. In the remaining 23 there was improvement under therapy with cortisone, the administration of which was continued on admission to hospital.

Bohman classified these 323 patients according to the side-effects or complications of cortisone treatment. Of the 91 who showed some side-effects, 39 had psychic disturbances which usually took the form of depression or anxiety. In some apathy and lassitude were the most prominent symptoms. Aggressiveness and dysphoria were also noted. The edema observed in 40 was, in 23, confined to the lower extremities, chiefly below the knee on both sides. In nine the edema was confined to the face and in eight to both face and legs. Dyspeptic symptoms suggestive of gastritis or peptic ulcer were observed in 23. In eight of these there was radiologic evidence of peptic ulcer. The thrombopenia observed in 12 was never severe, the lowest figures ranging from 149,000 to 193,000. Though there might be some doubt as to a causal relationship between the thrombopenia and the cortisone, no other possible cause of the former could be found in these 12 patients.

Staphylococcic Enteritis and Antibiotics.—Dr. T. Wiklund (*Nordisk medicin*, Sept. 18, 1958) illustrated a discussion of serious staphylococcic infections following the use of broad-spectrum antibiotics with the following case report. A candidate for appendectomy was not operated on because of bronchitis, expectant treatment being adopted with the administration of a total of 3 Gm. of oxytetracycline. On the fourth day of this medication abdominal pain and diarrhea set in, proving refractory to treatment and terminating in death four days later. Cultures confirmed the diagnosis of staphylococcic enteritis, and autopsy revealed a pseudomembranous esophagogastroenteritis. In another patient in whom the lungs had been operated on preoperative and postoperative treatment with penicillin and streptomycin was followed by intractable, fatal enteritis. In a third patient who also died of enteritis, streptomycin had been given by mouth in an attempt to sterilize the digestive tract as a preliminary to a colonic resection. In most such fatal cases of staphylococcic enteritis the blame was put on the broad-spectrum antibiotics given by mouth, but this mishap may also follow the parenteral administration of combined penicillin and streptomycin. The clinical findings are well defined, with abdominal discomfort and diarrhea setting in three to five days after the institution of antibiotic treatment.

UNITED KINGDOM

Homes for the Aged.—It is estimated that by 1977 there will be nearly 500,000 people aged over 75 in Britain. In the last 10 years the number increased by 25% and is now 281,000. The Minister of Health believes that the best place for old people is their own homes. The provision of as many one-bedroom units as possible is needed. Since 1952 the proportion of this type of house increased from 7.5 to 13.5%. The minister has opened a $200,000 home, the first to be built in South Wales specifically for old people. It will accommodate 50 people who will pay between $5.60 and $14 a week for room and board.

Lord Amulree, writing in *Public Health* said few local authorities have interpreted their powers under the National Health Service Act to provide a domiciliary meal service differing from the meals-on-wheels service offered by many voluntary organizations. These are mostly for healthy pensioners. It should be possible, on a medical certificate, for sick or disabled persons to have meals delivered at least five days a week. Many more elderly persons could then be discharged from hospitals.

Lung Cancer Death Rates.—E. C. Hammond, in the *British Medical Journal* for Sept. 13, said that in 1955 the lung cancer death rate reported in England and Wales for men was 2.1 times as high as that reported in the United States and for women 1.6 times as high. A difference of this order of magnitude has existed in male rates for several decades, while prior to 1949 there was only a small difference in the female rates. Among both sexes in the middle-age and old-age groups there are proportionately more cigarette smokers in the United Kingdom than in the United States. On the other hand, at present, the number of cigarettes consumed per smoker per day is higher in the United States than in the United Kingdom. The proportion of male cigarette smokers who inhale appears to be about the same in the two countries. In the United States the average length of the remaining butt after a cigarette is discarded is about 31 mm.; about 5% are 45 mm. or longer, and about 9% are under 20 mm. in length. In the United States in 1957 the main stream smoke of the average cigarette contained about 2.6 mg. of nicotine and 42.8 mg. of tar. More recently, cigarettes with a relatively low content of nicotine and tar have become increasingly popular in the United States.

Current data do not support the hypothesis that a substantial proportion of the difference in lung cancer death rates between the two countries is attributable to differences in the use of cigarettes, but more detailed information on smoking habits and on the chemical composition of cigarette smoke in the two countries is needed before this can be definitely established. In both countries the death rate from lung cancer in smokers as well as nonsmokers is higher in urban than in rural areas. The difference in this respect is far greater between Liverpool and rural areas of Wales than between large cities and rural areas in the United States, but Merseyside (which includes Liverpool) has a higher death rate from lung cancer in men than any other region in England and Wales, so it cannot be considered as typical of the country as a whole. While it is possible that some of the difference in death rates from lung cancer may be due to such factors associated with urbanization as air pollution or occupational exposures, available evidence does not suggest that these factors can account for a large part of the difference. The reported death rate from cancer, exclusive of lung cancer, declined steadily from 1931 to 1956 in England and Wales but rose slightly in the United States during the same period. Differences in the diagnosis and recording of causes of death may account for a part of the difference between death rates from lung cancer in the two countries.

Health Levy.—A significant pointer to progressive Conservative thought on the National Health Service by Sir Keith Joseph, M.P. for Leeds North-East and joint secretary of the party's Health and Social Security Committees, was reported in the *Daily Telegraph* of Sept. 19. He suggested that there may one day be two levels of Health Service contributions, according to earnings. There will always be a ceiling to the amount that can be spent from taxation. Expenditure above this will have to be financed partly by contributions and partly by charges. As the service grows and improves there may be elements in it that can be charged to patients without discouraging early treatment or unduly burdening the ill. Such charges should be subject to a means test so that those least able to afford payment are exempt. Contributions, too, can grow as average earnings grow, and perhaps there may one day be two levels of contributions: a lower one for those in a lower bracket of earnings and a higher for those above. A graduated contribution, varying with earnings, would have to take personal circumstances into account and would quickly become a second tax system. It would be inexcusable if the government failed to provide essential health services simply because in their view no more cost should be borne by taxation.

The challenge of the next decade is that the Health Service must find some of its own needs by switching some of its present resources and using them even more effectively. Savings and improved value for money expended could be made in the cost of drugs, managerial efficiency, design of hospitals, and improved coordination between hospital, local authority, and voluntary services. So far as drugs are concerned, the greatest saving could be made by reducing the number of prescriptions or the taxborne cost of each one by, for instance, doubling the present charge per item. The time is coming, according to Sir Keith, for new bargain between the community and the general practitioner, a bargain in which the state, by some means, frees the practitioner from the economic incentive to maximize the number of his patients, regardless of the actual constructive treatment he is able or willing to give them. This would be a situation in which the good general practitioner could again earn more than his inferior colleague even though both look after the same number of patients of the same financial status. Some such bargain should emerge, but it will not cost less than now. It will cost more, at least in the short term, though long-term economies by better therapy and better service may emerge. Private practice should be encouraged and more physicians should depend for part of their living on it.

Asian Influenza.—An editorial in the *British Medical Journal* for Sept. 20 stated that past experience has shown that with the appearance of antigenically novel strains of influenza virus earlier ones disappear. Isolations of A virus strains since the Asian strain appeared in 1957 have been almost entirely of this new type. We may therefore expect that viruses closely related to the Asian will dominate the scene for perhaps a decade. In any case the attack of influenza is usually much the same from the patient's point of view. Many physicians will be asked about vaccination. Last year's experience showed that a vaccine made against the current strain and given in time generally diminished incidence by about 67%. The chances of catching influenza are presumably less than they were last winter. It is therefore a matter for personal choice rather than for a country-wide campaign whether, this coming winter, it is worthwhile to get protection from a disease that may not turn up.

WORLD HEALTH ORGANIZATION

Use of Oxygen-15 in Study of Pulmonary Malfunction.—At the Second United Nations International Conference on the Peaceful Uses of Atomic Energy, N. A. Dyson and co-workers (London) stated that the short-lived radioactive isotope, oxygen-15, potentially offers a safe and direct tracer method of studying both the intake of oxygen on inspiration and its clearance by the blood, in small regional volumes of lung. Hitherto, bronchospirometry has been almost the only method of comparing gas exchange in different regions of the lungs, but, since it entails the passing of catheters into the bronchi under local anesthesia so that the gas can be collected it is unpleasant for the patient and the conditions are hardly physiological. Moreover, only a comparison of the whole of one lung with the other is usually practicable. Thus, the use of oxygen-15 marks an important advance. Oxygen-15 is the longest-lived radioactive isotope of oxygen, yet it has a half-life of only two minutes. This short half-life means that a number of tests can be done serially with no residual activity, but it also means that the isotope must be prepared close to the patient. In common with many cyclotron-produced isotopes, oxygen-15 decays by positron emission, and consequently the annihilation gamma radiation from the lungs may be measured by external scintillation counters. By using pairs of counters connected in coincidence, the volumes examined may be restricted to small cylindrical cores through the lungs.

The results in normal subjects and in patients chosen to represent examples of extreme abnormality of ventilation and blood flow in the lungs were generally as expected. They showed that it is possible to measure the ventilation and clearance by the blood of small volumes of lung with useful accuracy. The ability to discriminate between small areas of lung was good, but the problem of examining a small, localized volume inside the lung (e. g., a cyst) was difficult because normal lung tissue was inevitably included in the field. The chief drawback of the technique as it stands is the poor repeatability of the measurements of clearance rate, and for these it may be necessary to explore parallel counting further with some sacrifice of spatial resolution in order to achieve higher counting rates. The radiation hazard associated with this test, using either parallel or coincidence counting, is acceptable.

Applications of Iodine-132.—At the same meeting K. E. Halnan and E. Eric Pochin (London) stated that iodine-131 has been widely used in the study of thyroid function and is of outstanding value for many clinical investigations. In two important respects, however, an iodine isotope with a much shorter half life, such as iodine-132, offers advantages. The greatest advantage in the use of I^{132} lies in the much smaller radiation doses delivered to the thyroid per microcurie administered, a given oral dose of I^{132} delivering from 1/40 to 1/100 the thyroid radiation received from an equal amount of I^{131}. This reduction in dosage is due not only to the short half-life of I^{132} (2.3 hours or less than 1/80 that of I^{131}) but also to the relatively slow course of radioiodine uptake into the gland from the circulation. In a normal thyroid gland iodine uptake will be only half completed in about six hours, and by this time 85% of the administered I^{132}, but only 2% of I^{131}, will have undergone decay. Repeated measurements of thyroid function after administration of thyrotropic or thyroid hormone may be of value also in certain cases.

Day-to-day tests with I^{132} will readily demonstrate an effect of a single injection of thyrotropic hormone on the normal thyroid or on the thyroid of most patients with hypofunction of the pituitary, but no effect will be demonstrable in patients with primary hypothyroidism. In clinical use it will usually be sufficient to give an injection of thyrotropin immediately after the first I^{132} test and then to repeat the test at the same time a day later. When the diagnosis of thyrotoxicosis is in doubt, it may be valuable to administer thyroid hormone to the patient for one week and then to repeat the I^{132} test, since the normal fall in radioiodine uptake does not occur in the hyperfunctioning gland. It appears therefore that the short half life of I^{132} gives it two substantial advantages over I^{131} both in diagnostic and in research examination of human thyroid function: a reduced radiation dosage to the subject investigated and convenience when repeating tests at short intervals. We have not found its preparation from tellurium-132 to involve any difficulty or hazard sufficient to outweigh these advantages.

Pituitary Ablation by Means of Radioactive Seeds.—At the same meeting Frank Ellis and co-workers (Oxford) stated that they had treated 42 patients who had mammary cancer with widespread metastases by inserting seeds. The results were not impressive statistically, but it must be remembered that all the patients treated had reached the stage when no more benefit could be expected by any other treatment, the possibilities of local irradiation, surgery, and hormone therapy having all been exhausted. Thus, any improvement in the patient's condition was sheer gain, and the considerations to be taken into account were chiefly the risk and discomfort of the operation and the risk and discomfort of complications. The risk of the procedure is small. No patient died as its immediate consequence. The discomfort immediately after the operation consisted chiefly of headache and slight nausea for two or three days and, less constantly, of diabetes insipidus. Of the 42 patients, 15 were improved. Three patients died in less than one week. All these had obvious liver metastases with jaundice and were recognized as deteriorating rapidly at the time of implantation.

Radioactive Gold in the Treatment of Ovarian Cancer.—At the same meeting J. H. Muller (Switzerland) stated that he had treated an unselected group of 51 patients who had ovarian cancer with radioactive colloidal gold (Au^{198}). All of the 10 patients in stage 1, 9 of the 13 in stage 2, 4 of the 10 in stage 3, and none of the 18 in stage 4 were alive and without symptoms after five years. These results indicate that such isotope administration is of definite value since it at least doubled the salvage rate of the ovarian cancer patients with surgically resectable primary tumors.

MISCELLANY

INTERNAL MEDICINE AND THE TRAINING OF INTERNISTS

Paul S. Rhoads, M.D.

Most of the readers of this journal, in rare moments of reflection and self-examination, must have pondered the questions: Of what does the practice of internal medicine consist? What is an internist? Since internists are supposed eventually to be certified by a specialty board, the implication is that they practice a specialized type of medicine. Doubtless, in some suitably remote repository the definition of this specialty lies entombed, but the fact remains that among both the public and physicians themselves there is much confusion as to what is embraced by this most all-inclusive of the specialties.

Some dictionaries sensibly ignore the question. A recent edition of Webster's unabridged dictionary defines internal medicine as, "That branch of medicine dealing with the diagnosis and treatment of diseases of the interior of the body," thus separating its practitioners from, at least, their dermatologic colleagues. "Dorland's Illustrated Medical Dictionary" takes a further step in describing it as "that department of medicine which deals with diseases that cannot be treated surgically," a novel segment of human ills delimited only by the imagination and industry of the surgeons. The same source goes a step further by defining an internist as "A physician who treats diseases of the internal organs," thus slicing off another segment. In Funk and Wagnalls large dictionary the only reference to internal medicine points out that this is a "remedy to be taken internally."

Such definitions obviously will not do. Yet, after several frustrating hours of search in one of America's best-equipped medical libraries, I was able to dig out no good statement of what is encompassed by the term. O. H. P. Pepper,[1] after a long preamble in which the difficulties of such an attempt were set forth, had a try at defining the practitioner of the specialty. "An internist is a physician fitted by sound and applicable knowledge of the basic sciences, a continuing training in internal medicine, a familiarity of fields outside his own, and an intellectual rather than a manual or technical approach, to study and treat the diseases of the field of internal medicine to which he strictly limits himself and to integrate with the knowledge of his own field that of the allied specialities." Dr. Pepper then modestly and truthfully admits that, since "internal medicine" eludes definition, this delineation of the internist is perhaps wide of the mark.

When asked to describe the tasks properly to be undertaken by an internist, I could not compose a definition but had this to say[2]:

> The average patient probably considers the internist a general practitioner particularly interested in diagnosis who has removed from his armamentarium the scalpel, trephine, forceps, plaster cast, and the countless other tools of his craft, confining his own therapeutic efforts to what can be written upon a prescription blank plus the hypodermic needle. This concept may be surprisingly close to the correct one. No specialist can approach in utility to the patient the general practitioner who by incessant study and necessity has mastered the staggering body of medical knowledge and the skills of a dozen surgical specialties required to make him competent to take care of nearly all the needs of those who come to him for help. However, this breed of doctor is almost extinct, for medical knowledge is too diverse and too technical for any one man to acquire all of its essentials.
>
> The "medical man" must strive to come nearest this ideal doctor more than any other of the specialists. It is he to whom the patient may properly turn as having the final word in determining what is the matter and what is to be done. The internist should not operate if a competent surgical colleague is available and usually could not anyway; but he must have enough knowledge of the problems of general surgery, gynecology, obstetrics, otolaryngology, ophthalmology, neurosurgery, genitourinary surgery, and all the other subspecialties so that he will know when surgery is indicated and whom he should call upon for help. Having called in another consultant and concurred in the diagnosis he must accept responsibility for the outcome along with his colleague.

In his delightful essay, "Internal Medicine as a Vocation,"[3] Sir William Osler, while regarding internal medicine as a field set apart, wisely refrains from defining it as a specialty. He says in part:

> I wish there were another term to designate the wide field of medical practice which remains after the separation of surgery, midwifery and gynecology. Not itself a specialty (though it embraces, at least, half a dozen) its cultivators cannot be called specialists, but bear without reproach the good old name physician, in contradistinction to general practitioners, surgeons, obstetricians and gynecologists.

He then goes on to point out his own high standards for those to be regarded as internists. Among his recommendations were a 10-year period of "dry bread years" in which were recommended study abroad or at least in other medical centers in this country, some years in general practice, much work with outpatients and without too much preoccupation with "quiz classes" and "journal work." He strongly advised more than passing familiarity with one or all of the disciplines of chemistry, physiology, and morbid anatomy. Of the three, some special knowledge of morbid anatomy was considered most essential for the clinician.

It is obvious that the composite of "internal medicine" cannot be neatly encompassed by a definition. There are just as obviously widely differing opinions as to the kind and amount of training required by those who wish to be internists. To some this dilemma may appear to be of purely academic importance. To others, who after five years of postgraduate preparation are about to take Board of Internal

---

Editorial reproduced from A. M. A. Archives of Internal Medicine, October, 1958.

Medicine examinations, the question is practical and urgent. Upon their estimate of what, in the minds of the Board examiners, makes up the body of facts and skills which the internist should have for minimum equipment can depend success or failure in the Board examinations. Without going into the question of whether one who fails in the examination can or cannot be as effective an internist as one who passes, the fact is that unsuccessful candidates for Board certification are for the most part denied recognition as capable consultants. Admission to many hospital staffs and medical societies, advancement in academic rank in medical schools, and other privileges are denied to them. Members of the Board have from time to time deplored this practice of making differentials in emoluments and promotions contingent on Board certification, but the practice is here, and young internists know they had better get Board certification. One of the kindest and wisest of the Board chairmen gave the admonition that "the responsibility of acquiring knowledge rests with the candidate and the responsibility of maintaining the standards of knowledge required for certification rests with the Board."[4] In the long run, however, the future of internal medicine depends largely not upon what each person thinks should make him a good internist but what the Board collectively thinks.

Up to now, there has been little to criticize in either the personnel or the decisions of the Board of Internal Medicine. From the outset, thoughtful conscientious men have tried to lay down rules rigid enough to assure quality in the product of the training programs but flexible enough not to cramp the individual interests of the candidates in these all-important years of their development.

In 1940 Dr. Irons[5] quoted from the brochure of the Board:

> The American Board of Internal Medicine does not propose to establish fixed rules for the preliminary training of candidates for certification in this field. Broad general principles for training, however, may be outlined—"A sound knowledge of physiology, biochemistry, pharmacology, anatomy, bacteriology and pathology as they apply to disease is essential for continued professional growth of the individual who practices internal medicine. Such knowledge may be acquired in a number of ways. These include sciences closely integrated with clinical facilities, and service in well organized clinics or in preceptorships."

No one can question the desirability of such emphasis on the nonclinical disciplines or the wisdom of the declaration to keep the program very flexible, and yet time spent in a preceptorship part of the original program[6] is now unacceptable to the Board and for very understandable reasons.

There are differences of opinion as to what constitutes "sound knowledge" of the nonclinical subjects listed above. Some members question whether one year in one or more of these branches is enough—certainly there can be no prolonged special training in all of them. Others question the value of even a year of research experience as an integral part of the training of a resident. Lewis[7] feels that above all else an internist must have the capacity to make a thorough physical examination and to take a good history and make a penetrating analysis of it. In his view two years is too little time to develop in most of the candidates the broad knowledge of medicine and clinical skills that are required of internists. He thinks only those with more than average interest and aptitude for research should be required to participate in it. "If we are to do our job as I see we should do it, we will have to take an almost heretical course and decide that we will train some of our apt young men to become expert clinicians and clinical teachers and others to be investigators."

These points are well taken. The Board has made a real effort to make the program for qualification flexible enough to adapt itself to the special circumstances of physicians who have prepared themselves as specialists in internal medicine in a variety of ways. Plan H, the one most recently adopted, makes it possible for a man committed particularly to research and academic medicine to spend the two required postresidency years chiefly in the laboratory, provided he keeps his hand in clinical medicine by work in the hospital wards or dispensary once a week. Such men must be specially recommended for this privilege by the professors of medicine in the schools which they serve.

Whether other young internists not aiming for teaching careers but with strong research interests could not similarily benefit from two years with more emphasis on research and less on "practice" is a question that must be answered on an individual basis.

Dr. Irons, in his discussion of Board examinations points out that the written questions are so designed as to test the powers of the candidates to come to proper conclusions after certain clinical data are stated rather than to delve too deeply into their factual knowledge. In grading, more attention is given to logical deductions than to "right answers." Such emphases in evaluating the examinees are praiseworthy but difficult of attainment. Even more difficult, but much more important at this stage of a young man's development, is the evaluation of intangibles. In other words, what kind of a doctor should be encouraged to enter the field of internal medicine?

1. Is he impulsive or does he have the patience for long hours of continued study and for careful but monotonous tasks in the laboratory?
2. Does he have the conviction that *every* patient is important and worthy of his help whether he can pay for it or not?

3. Does he have sustained enthusiasm? Will he willingly undertake the painstaking preparation required to make him a good teacher?

4. Does he have enough devotion to his job to look up what he doesn't know, to make house calls, to get up at night when needed?

5. When called upon for a consultation will his efforts be devoted to helping his colleague to do what is best for the patient or to impressing the patient?

No one will deny the importance of such intangibles, yet how can an examining Board make such evaluation?

No Board can make rules which will answer all of these special problems of the peculiar division of medicine occupied by the internists, and yet a recognition of the problems suggests some changes that might help.

The present steps being taken by investigating committees from the College of Physicians to learn more about what makes up the residency program in the various approved hospitals should prove most constructive. If carried on perceptively it could furnish some indication of what the various internists in charge of residency programs consider important and of the way these ideas are implemented. More important, some evaluation of the teachers themselves could be had.

From an interchange between teachers in the various hospitals and the Board more minds could be brought to focus on the problem of arriving at some clearer definition of the minimum body of knowledge and skills which should reasonably be required of all internists. Perhaps an examination devised to test a candidate's grasp of the "fundamentals" so agreed upon could be given at the end of the three-year residency program. Successful candidates could then go about the next stage of their "dry bread" period pursuing their particular fields of interest in a more relaxed frame of mind.

Only those who have seen young men "sweat out" the year or two before their examination frantically reading textbooks and journals in the hope of cramming in enough facts in all the fields of internal medicine to satisfy the examiners can be aware of the anxiety produced in them. Few persons will question the value of high standards and the necessity of examinations to maintain them. However, could not these two or three years be spent more usefully if a candidate could be assured that the decision regarding his certification would be made on the basis of such points as the following?

1. Consideration of a comprehensive report on his performance by certified internists and faculty members of medical schools to whom the candidates had been assigned for guidance and supervision. From these reports would come information on the "intangibles."

2. Demonstration of the ability to take a good history, make a good physical examination, and make logical conclusions and recommendations after reviewing the laboratory data on one or two patients chosen at random.

3. Demonstration of a fairly good grasp of fundamental knowledge of internal medicine as a whole plus more complete knowledge in the field of his special interest, such as cardiology, metabolic diseases, or infectious diseases.

Implementing of Point 3 would require assignment of candidates to examiners, some of whom would have special interests in the same field as those of the candidate. In case of disagreement in evaluation by two examiners, a third should be called in before a candidate is failed. At this stage of a man's training the psychologic impact of failing is too devastating for the decision to be reached with any hint of haste or unfairness. If an unfavorable verdict is reached, and inevitably this will happen in many cases, the candidate should be entitled to a consultation with members of the examining board for counsel as to how his deficiencies might best be remedied or whether or not he should change direction.

It should be pointed out again that I have the highest admiration for every one of the present members of the Board of Internal Medicine and a profound appreciation of the difficult task they face.

In friendly discussions various members sharply disagree with some points brought up here—on perfectly reasonable grounds. However, since our specialty has special problems not faced by more narrow ones, a full discussion of the manner in which its practitioners are to be trained seems to be in order. The public should be assured of a quality product. On the other hand, care must be taken not to cramp the development of young men of imagination and unusual initiative by insisting on a too rigidly standardized training program.

BUSINESS PRACTICE

This is the fifth in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

FINANCING THE ESTABLISHMENT OF AN OFFICE

Setting up a medical office requires money—specific outlays for rent, equipment and furnishings, and possibly some remodeling, as well as enough to cover the doctor's living expenses during the practice-building period.

A physician is usually considered an excellent credit risk, but banks generally are not permitted to make unsecured loans. In the beginning, then, it may be wise to turn to the companies who outfit doctors' offices. Such companies will often help him finance his office if properly approached. The physician's first job is to appraise his actual financial needs over a period of several months, taking stock of his own reserves.

His financial evaluation sheet might include items like these: (1) cash on hand—income from part-time job as insurance examiner during first six months of practice, estimated income from practice during first six months; and (2) needs—first and last month's office rent, minor office alterations, office furniture, cost of instruments and equipment, cost of basic office supplies, stationery, cards and business records for office, estimated utilities, telephone charges at start, cost of necessary licenses and permits, estimated living expenses for first few months, including operation of car, and insurance.

Balancing his assets against his estimated expenses will give the new physician a rough idea of his financial needs. He will be in a better position to approach the people who can provide the necessary capital armed with facts and figures. His worst mistake would be to misrepresent his needs or current financial situation.

The companies which sell a physician equipment, supplies, and furniture are usually most liberal in extending credit and liberal payment terms. Some items of equipment, such as an x-ray unit, can be rented until the doctor can afford to buy one.

The physician should make a get-acquainted call on the president or an officer of the bank and state his intentions of opening an office. He can explain why he chose this particular community, announce his intentions of opening an account with the bank, and establish friendly rapport. If he does need a loan, the doctor's approach should be direct and business-like rather than apologetic. He is not asking for a favor but is presenting a business proposition. Prepared to lay all his cards on the table, the doctor is in effect saying: "Considering these facts, how much can you lend me?" If the banker is "sold" on the physician as a risk and the proposition outlined, he probably will lend all the law permits. A physician who makes his problem so interesting that the banker becomes interested in helping him solve it will fare well.

If a doctor still has need for additional funds, there are other sources he can investigate. He can check private loan companies or call on prominent citizens in the community he has selected, using the same approach he used on the banker. It is always easier to raise money in the community where he plans to practice. However, at this point a word of caution must be injected. Do not try to get everything at once if it involves an overload of debts. It is sometimes best to plan ahead for what seems to be a present need than to buy just because you can get it on credit.

Protecting Your Credit

Only the physician himself can protect his credit. Credit is based on confidence—faith in the person to whom it is extended. It is no sin to be in debt, but the doctor should clear up his indebtedness as soon as possible. Here are tips on guarding credit:

1. In paying all obligations, interest payments come first.

2. Pay all commercial bills promptly when due. If this is impossible, make a personal call on the store's credit officer, explain why payment is impossible, and tell him when it can be paid.

3. Because a physician cannot estimate monthly income at the start of his practice, it is best to make arrangements for repayment of the entire amount of a bank or personal loan at some specified date rather than on a monthly basis. Three to six months are customary time limits on unsecured loans, but notes can be renewed. Keep a calendar showing date of expiration for each note, and, if it cannot be repaid then, arrange to renew before it becomes due.

MEDICAL FILM REVIEWS

From the Heart of Town: 16 mm., color, sound, showing time 13 minutes. Produced in 1958 by William J. Ganz Company, New York, for E. R. Squibb and Sons, Division of Olin Mathieson Chemical Co., New York. Procurable on loan or purchase ($35.50) from American Red Cross, 1730 E St. N. W., Washington, D. C.

This film depicts the visit of a bloodmobile to a typical American town and demonstrates that community-level cooperation is essential to the success of the blood program. It tells of a community's preparation for and response to the visit of the bloodmobile and also shows how scientific research is developing the "prescription for life," including such blood products as gamma globulin, serum albumin, and fibrinogen and also the methods for obtaining, handling, storing, and processing whole blood. On the whole, this is a good film. Especially important is the section which deals with the various uses of the blood. Another important point which is brought out clearly is that industry also donates its services through research. The photography is very good. This film is recommended for use in local organizations, such as churches, civic groups, and schools in communities which are organizing a program of this kind.

A Career in Bacteriology: 16 mm., color, sound, showing time 15 minutes. Produced in 1957 by and procurable on loan ($5.50) or purchase ($150) from Audio Visual Center, Indiana University, Bloomington, Ind.

The purpose of this film is to develop an interest in bacteriology as a vocation, to show the studies in bacteriology pursued by college students, and to present the various vocational opportunities for those who study bacteriology. By photomicrography it shows protozoa, algae, molds, yeast, and bacteria, and by animation it shows the minute size of bacteria and their rapid rate of reproduction. Some of the actions of micro-organisms in the cause of and treatment for diseases, in the maintenance of soil fertility, and in the production of food for humans and food supplements for livestock and poultry are pointed out. This film aims primarily at making the profession of the bacteriologist attractive to the senior high school student and the college student in his first or second year before he has made up his mind about the choice of a career. It will also be of interest to the physician who is asked to speak on careers in the medical and health field. It may be of interest to the nurse, medical student, and public health worker. On the whole, it is well done technically and is correct factually.

You Are There: The Discovery of Anesthesia: 16 mm., and white, sound, showing time 25 minutes. Produce 1956 for CBS Television. Procurable on rental or purch ($135) from McGraw Hill Book Co., 330 W. 42nd St., N York 36, or on loan ($2) from Motion Picture Librar American Medical Association, 535 N. Dearborn St., Chicago 10.

This is a dramatic and exciting presentation of the facts surrounding the discovery of anesthesia. Although certain small freedoms were taken with facts in order to make a more dramatic and pictorial presentation, in general, this is a very accurate portrayal of the early days of the discovery of anesthesia. One gathers from this picture that Crawford Long performed surgical anesthesia prior to Wells and Morton. Yet, he did not give this discovery to the world. There can be little doubt, however, that he deserves a place in the early discoverers because of his prior use of surgical anesthesia. That Wells had utilized anesthesia successfully in dental cases prior to Morton's surgical discovery on Oct. 16, 1846, is brought out in the film but somewhat slighted, as is the work of James Young Simpson. The place that Morton plays in the discovery of anesthesia is well portrayed. There can be little doubt but that this man, so beautifully portrayed in this movie, really gave anesthesia to the medical profession. This film is an excellent digest in portraying the discovery of anesthesia and is suitable for lay audiences, medical students, interns, residents, nurses, and the allied professions. The sound, photography, and over-all dramatic presentation are excellent.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Clinical Reconstruction of the "Bangungut Syndrome." J. B. Nolasco. J. Philippine M. A. 34:371-376 (June) 1958 [Manila].

The term "bangungut syndrome" had been coined to cover the typical signs and symptoms and the postmortem findings in young Filipinos who died suddenly during sleep after a heavy meal; "bangungut" is the Tagalog word for nightmares, which was chosen from common usage for convenience and not from agreements with the common belief that nightmares caused these unexplained deaths. The author reports the case of a 27-year-old man with bangungut syndrome, who, unlike the patients reported on previously, was able to tell some of his subjective feelings and who was subjected to at least a cursory physical examination before he died. A few hours before admission this patient had convulsive seizures, with groaning, lasting for several minutes while he was asleep. On regaining consciousness, he complained of epigastric pain, nausea, and salivation and was taken to hospital. On admission, the heart sounds were weak, the pulse imperceptible, the blood pressure was zero, and the pupils were symetrically dilated. Shortly after being placed in bed the patient had convulsive seizures, with transient cyanosis, groaning, rolling of the eyeballs for one minute followed by relaxation of the body, pallor, a short heaving respiration, and then apnea. Artificial respiration was applied, but the patient died.

With the clue given by this patient, the author began to be on the lookout for patients coming to the hospital at night with complaints referable to the respiratory, central nervous, circulatory, and digestive systems. Thus, the cases of 2 men and 2 women, between the ages of 17 and 51 years, were collected, which were considered to represent early stages of the bangungut syndrome. Two of these patients had nightmares; all of them had difficulty in breathing. One patient, a medical student, noticed decreasing pulse volume and rapid pulse; another had hypotension and tachycardia; the remaining 2 patients showed normal blood pressure levels, but their blood pressures were determined several hours after the attacks. Three had symptoms referable to the central nervous system, such as heaviness of the head, numbness, or loss of consciousness. Retinal edema was observed in one. All the patients gave a history of having previously eaten preserved fish or foods which have been considered as "bangungut-genic." A brother of one also had nightmares after eating the same food as the patient. Thus, the clinical features of the bangungut syndrome, so far detected, are as follows: The patient has eaten preserved fish or fish products; the acme occurs while the patient is asleep; manifestations may progress to death or may completely disappear within 24 hours; the respiratory, central nervous, circulatory, and digestive systems are the organ systems usually involved.

Aregenerative Anemia Associated with Benign Thymoma. B. Clarkson and D. J. Prockop. New England J. Med. 259:253-258 (Aug. 7) 1958 [Boston].

The authors present the histories of 2 patients in whom aregenerative anemia was associated with benign thymoma and point out that 14 cases with this syndrome have been described before. The suggestion that the association of thymoma and aregenerative anemia was not a matter of chance was first made by Humphreys and Southworth in 1945, when they found that cure of the anemia followed removal of the tumor. Thymectomy has been performed on 8 of 9 patients with the combination of thymoma and aregenerative anemia described since then, but the results of thymectomy have been far from uniformly successful. Only 1 of these 8 patients was cured, and 2 others obtained some alleviation of their anemia. One died within 24 hours of operation, and the other 4 had no apparent benefit from the operation. The 2 patients presented here likewise derived no benefit from the resection of the thymoma. One of the 2 patients is unusual in that the thymoma was removed 2 years before the development of the anemia.

No therapy, other than blood transfusions, was of benefit in patient's not responding to thymectomy, except perhaps splenectomy and corticotropin therapy in 2 patients. An extract prepared from the thymoma in one of the patients was infused intravenously for 10 days into a dog that had pre-

Two of these patients had nightmares; all of them had difficulty in breathing. One patient, a medical student, noticed decreasing pulse volume and rapid pulse; another had hypotension and tachycardia; the remaining 2 patients showed normal blood pressure levels, but their blood pressures were determined several hours after the attacks. Three had symptoms referable to the central nervous system, such as heaviness of the head, numbness, or loss of consciousness. Retinal edema was observed in one. All the patients gave a history of having previously eaten preserved fish or foods which have been considered as "bangungut-genic." A brother of one also had nightmares after eating the same food as the patient. Thus, the clinical features of the bangungut syndrome, so far detected, are as follows: The patient has eaten preserved fish or fish products; the acme occurs while the patient is asleep; manifestations may progress to death or may completely disappear within 24 hours; the respiratory, central nervous, circulatory, and digestive systems are the organ systems usually involved.

Aregenerative Anemia Associated with Benign Thymoma. B. Clarkson and D. J. Prockop. New England J. Med. 259:253-258 (Aug. 7) 1958 [Boston].

The authors present the histories of 2 patients in whom aregenerative anemia was associated with benign thymoma and point out that 14 cases with this syndrome have been described before. The suggestion that the association of thymoma and aregenerative anemia was not a matter of chance was first made by Humphreys and Southworth in 1945, when they found that cure of the anemia followed removal of the tumor. Thymectomy has been performed on 8 of 9 patients with the combination of thymoma and aregenerative anemia described since then, but the results of thymectomy have been far from uniformly successful. Only 1 of these 8 patients was cured, and 2 others obtained some alleviation of their anemia. One died within 24 hours of operation, and the other 4 had no apparent benefit from the operation. The 2 patients presented here likewise derived no benefit from the resection of the thymoma. One of the 2 patients is unusual in that the thymoma was removed 2 years before the development of the anemia.

No therapy, other than blood transfusions, was of benefit in patient's not responding to thymectomy, except perhaps splenectomy and corticotropin therapy in 2 patients. An extract prepared from the thymoma in one of the patients was infused intravenously for 10 days into a dog that had pre-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

viously been given acetylphenylhydrazine to induce an anemia and erythroid hyperplasia. No inhibition of erythropoiesis was produced by the thymoma extract. The establishment of the true relation between thymoma and aregenerative anemia will require further studies on patients who have this combination. If normal erythropoiesis had developed after thymectomy in their second case, the authors had planned to attempt to reproduce the anemia by injecting an extract of the tumor. This should probably be tried when further patients are found who are benefited by removal of the tumor.

Giant-Cell Granuloma of the Respiratory Tract (Wegener's Granulomatosis). E. W. Walton. Brit. M. J. 2:265-270 (Aug. 2) 1958 [London].

The author reports on 7 men and 3 women, between the ages of 33 and 75 years, with a syndrome characterized by symptoms of progressive ulceration in the respiratory tract, together with signs of widespread inflammatory disease to which the name "Wegener's granulomatosis" has been applied by other workers. Forty-six additional cases of this syndrome in 26 male and 20 female patients, between the ages of 12 and 70 years, were selected from the literature. Two groups were distinguished as follows: In the first group of about 40 patients, persistent purulent rhinorrhea was accompanied by nasal obstruction and crusting, antral pain, and epistaxis. Otorrhea, deafness, or ulceration of the gums were the initial symptoms in a few of these; later rhinorrhea occurred in each. In the second and smaller group, attention was drawn to the lungs because of chronic cough, hemoptysis, or pleurisy. Often the constitutional upset was out of proportion to the apparent intensity of the local lesion, and the patients sought advice because of persisting malaise, fever, or weakness. The course was usually rapid, progressing to death in 5 months, on the average, and occasionally in 4 weeks. Five of the 56 patients had a more chronic illness, with periods of remission and survival up to 4 years. Though temporary improvement sometimes followed antibiotic treatment, the local lesion always persisted. Spread of the inflammatory process led to extensive mucosal ulceration and cartilaginous or osseous destruction in the nose and palate of the patients in the first group, and to widespread pulmonary consolidation in those in the second group. Sooner or later signs of widespread inflammatory disease, such as fleeting arthralgia, numbness and tingling in the extremities, sensory loss, muscle weakness or paralysis, and a hemorrhagic vesicular rash, most frequent on the skin of the face, wrists, and elbows, and the oral mucosa, occurred in all the patients. On roentgenologic examination, the lungs of 38 patients showed dense circular or oval opacities in one or more lobes, often with central cavitation, and varying in size up to that of a hen's egg. Less often bronchopneumonic infiltration was the only notable change.

The basic pathological features were giant-cell granulomatous ulcers at one or more levels in the respiratory tract; the ulcers involved the nose and paranasal sinuses in 34 patients, palate and pharynx in 21, tongue in 7, larynx in 14, trachea in 17, and bronchi in 23. In addition to the ulceration of the respiratory tract, widespread giant-cell granulomas and necrotizing lesions of small vessels were observed. The characteristic round or oval consolidations in the lungs were not infarcts but conglomerate areas of peribronchial necrosis. The kidneys were severely affected in all but 3 patients; enlargement and blurring of the architecture were the usual macroscopic changes, and focal "fibrinoid" necrosis of glomerular loops and periglomerular granulomatous inflammation were almost constant microscopic findings. The disease is clearly a separate entity, differing both clinically and in the character and distribution of the lesions from similar conditions, such as polyarteritis nodosa and malignant granuloma. It begins as a progressive ulceration of unknown causation in the respiratory tract. Sooner or later widespread lesions, the result of a hypersensitivity reaction, complete the aspect of the disease. Treatment should be primarily directed toward healing of the initial lesion, and radiotherapy proved to be successful in some cases, with control of secondary infection by suitable antibiotics. Administration of cortisone or other steroids is the treatment of choice, once widespread lesions have occurred.

Precirrhosis: Its Clinical Entity. E. Aron and P. Jobard. Arch. mal. app. digest. 47:849-860 (July-Aug.) 1958 (In French) [Paris].

Cirrhosis is characterized by a structural derangement of the liver caused by extensive generalized fibrosis. Exact classification of the various stages of the disease is based on the anatomic appearance of the liver, but for the practitioner cirrhosis may be regarded as either a hypertrophic or an atrophic process leading to failure of hepatic function, hemorrhage, ascites, and edema. Hepatologists who have studied the cirrhotic process distinguish 2 stages in its early development: (1) alcoholic precirrhosis, which comprises all forms of alcoholic hepatitis, steatotic and cytolytic, in which the 3 histological elements characteristic of cirrhosis (a zone of cellular atrophy, hyperplastic nodules, and sclerosis) are present in varying combinations and to varying degrees, and (2) beginning alcoholic cirrhosis, in which the cirrhosis is clearly established. Obvious alcoholic cirrhosis in its later form, when it can be diagnosed on the basis of the clinical findings without recourse to laboratory studies, should be regarded as a terminal stage of the disease. Distinction between the precirrhotic and cirrhotic stages is not always easy; systematic examination of the liver in alcoholic patients often reveals histological evidence of anatomic cirrhosis, which cannot be confirmed either by the clinical signs or by the results of biological tests. Similarly, the histological aspect of the liver does not always indicate the subsequent course of the disease. Thus, simple steatosis may be associated either with a minor clinical state or with a course of the utmost gravity. This absence of parallelism between the histological and biological findings, on the one hand, and the clinical symptoms, on the other, which was evident in many of the 166 alcoholic patients admitted to the authors' service in 1957, is discussed in greater detail on the basis of 9 illustrative case reports.

The data presented suggest the advisability of regarding all enlargements of the liver in alcoholic patients as precirrhotic, keeping in mind, however, the important fact that enlargement of the liver is not always present in these patients. Alcoholic precirrhosis should not be neglected or dismissed as commonplace; on the contrary, it should be regarded as an extremely serious condition which has an unpredictable course and which must be treated promptly and energetically. Prompt treatment, with complete elimination of alcohol, in the precirrhotic period, which may extend over many years, is, in fact, the only way to prevent the development of cirrhosis.

Carcinoma of the Colon under the Age of 40. J. A. Ezzo, J. F. Sullivan and R. E. Mack. Ann. Int. Med. 49:321-325 (Aug.) 1958 [Lancaster, Pa.].

Of 840 patients with pathologically proved carcinoma of the colon, who were admitted to the St. Louis University Hospitals between January, 1950, and May, 1957, 32 (19 men and 13 women) were under the age of 40 years. Twelve of them, who were between the ages of 23 and 39 years, had carcinoma of the rectum. Eight of these patients died 3 to 58 months after the diagnosis. The remaining 4 patients were alive and well 5 to 24 months after the diagnosis was made. The remaining 20 of the 32 patients had carcinomas of other portions of the colon than the rectum. One patient could not be followed up and is presumed to be dead. Thirteen patients died within 3 to 28 months after they had been seen. Two patients are alive but have metastatic disease 6 and 24 months after the onset, and 1 patient is alive 6 months after operation for a ruptured carcinoma of the cecum. The remaining 3 patients are alive and well 1 to 4 years postoperatively. Thus, of a total of 32 patients with malignant tumors of the colon, 25 are dead or fatally ill. Seven patients are living without disease 5 to 48 months postoperatively. If one presumes that these 7 patients will live 5 years or more, the very best the 5-year survival rate can be is 21.7%.

It is difficult to explain the very poor prognosis in this group of young patients. Their symptoms, including melena, pain, constipation, diarrhea, and weight loss, had been present for the same period of time as in the older patients. Surgery was not unduly delayed in any patient. As a group these patients were better operative risks than their older counterparts, and, although operative mortality rates reported by other workers have generally been quite high, varying from 3.0 to 9.6%, there were no operative deaths in this series. The absence of lymphatic or vein invasion at the time of surgery was of little prognostic value. Two patients who had had no evidence of spread at surgery died of metastatic disease within one year. This observation confirms Dukes's statement that lesions of the rectum give rise to metastases more rapidly in young patients than in those who are older. Carcinoma of the colon apparently has an accelerated course in patients under 40 years of age.

Chronic Adrenocortical Insufficiency (Addison's Disease). A. M. de Andino Jr. and J. Pérez Cruet. Bol. Asoc. méd. Puerto Rico. 50:163-170 (May) 1958 (In English) [Santurce].

Chronic adrenocortical insufficiency either is idiopathic or is caused by tuberculosis of the adrenal gland and, more rarely, is due to bilateral tumoral metastases, leukemic infiltration, amyloid disease, hemochromatosis, or histoplasmosis. The disease is characterized by malaise, fatigability, gastrointestinal disorders, loss of weight, progressive anemia, low blood pressure, dizziness, a weak heart, severe prostration, bronze-like pigmentation of the skin, mental disorders, and loss of the sexual function. The disease is either congenital or acquired. The congenital type is seen in premature infants whose mothers have had deficient adrenocortical secretion; the infants die in the neonatal period. The disease of the acquired type may be transient, such as that which follows administration of steroids for a prolonged period, or it may be primary and complicated by tuberculosis or other chronic infection.

The authors report the first proved case of chronic adrenocortical insufficiency in a Puerto Rican woman, 48 years old. The symptoms were typical and had lasted for 8 months when the patient reported to hospital. The patient was given cortisone, 200 mg., Cortate, 10 mg., and an intravenous drip of 1 liter of 5% dextrose in isotonic sodium chloride solution. The maintenance treatment consisted of a daily dose of cortisone, 20 mg., of Cortate, 4 mg., and of sodium chloride, 8 Gm. The treatment was continued for 3 consecutive weeks, discontinued for 3 weeks, given for 2 weeks, discontinued for 3 days, and again given, a dose of 12.5 mg. of cortisone being administered for 2 more weeks. The treatment of pulmonary tuberculosis was started immediately upon the patient's hospitalization and was continued throughout the treatment for chronic adrenocortical insufficiency. It consisted of the administration of isoniazid in daily doses of 300 mg. and of streptomycin in daily doses of 1 Gm. At the end of 3 months of hospitalization and treatment, the symptoms of adrenocortical insufficiency had disappeared. The patient gained 26 lb. in weight. She was transferred to a hospital for tuberculous patients for further antituberculous treatment.

The Serum Protein Picture in Gastroduodenal Ulcer. R. Dupuy and A. Beaune. Semaine hôp. Paris 34:1979-1982 (July 18-28) 1958 (In French) [Paris].

Published data on protein metabolism in patients with ulcer have been reviewed, together with the authors' own observations on 36 patients. It appeared, in spite of some contradictory findings, that abnormal serum protein levels were present in all the patients with gastroduodenal ulcer. This abnormality affects either the total protein level or the various protein fractions or, concurrently, one protein fraction and the total protein level. Moreover, the serum protein picture does not seem to be influenced by antalgic drugs during the acute stage of the ulcerative disease. The protein picture of the patients was abnormal, not only during periods of acute pain but also during periods of remission, during which it was characterized by great instability. The transition from a period of remission to an acute stage of the ulcerative disease is apparently accompanied by an increase in the disturbances in the serum protein level. The changes observed in the serum protein values differed in patients belonging to different ethnic and geographic groups, but whether these differences are due to ethnic or to nutritional or climatic influences is not now known.

Influence of Protein Therapy on the Serum Protein Picture in Patients with Ulcer. R. Dupuy and A. Beaune. Semaine hôp. Paris 34:1983-1986 (July 18-28) 1958 (In French) [Paris].

The occurrence of abnormalities in the serum protein picture in patients with duodenal ulcer during periods of painful exacerbation, previously reported by the authors, has been confirmed by further studies. These changes can be corrected, at least partially, by intravenously administered protein. The 36 patients studied were given protein in the form of peptones in 30 intravenous injections distributed over 30 or 60 days, as required in each case. The results were verified by a standard procedure, consisting of 3 determinations of the serum protein level at certain intervals: the first, before treatment; the second, 5 to 10 days after the beginning of treatment; and the third, at the end of treatment, i. e., 30 or 60 days after the first examination. Treatment brought about a decrease in elevated serum protein values and an increase in those that were reduced. As a general rule, the serum albumin level, which was increased at first, decreased steadily from the beginning to the end of treatment, usually reaching nearly normal values. The serum globulin level, which was normal at the beginning of treatment, increased during the first days of treatment and then returned to the initial value. These variations in the serum albumin and the serum globulin level led during the first phase of the treatment to a significant decrease in the albumin-globulin ratio; the ratio might later increase slightly, but in any case it would settle down at the end of treatment to a level that was nearly normal and was lower than it was in the beginning. By contrast, the serum protein titers in patients with ulcer do not seem to be corrected by various other treatments, such as gastric fomentations or the administration of protein hydrolysates or vitamin or atropine compounds.

The mechanism by which protein therapy acts to produce changes in the serum protein picture is not yet clear, but the indications are that the peptones have an anti-inflammatory effect and that they also act specifically on the reticuloendothelial system. Further study will be needed to clarify these points and to establish the extent to which protein therapy may be regarded as a specific treatment for duodenal ulcer.

Adrenal Hypofunction After Corticoid Withdrawal. A. Vermeulen. Acta endocrinol. 27:321-330 (July) 1958 (In English) [Copenhagen].

Since the introduction of such potent synthetic glucocorticoids as prednisone and prednisolone, the incidence of adrenocortical hypofunction has increased. These steroids are at least 4 times as active in depressing adrenocortical activity as similar doses of cortisone. In view of these facts the author investigated the reactivity of the adrenal cortex to exogenous corticotropin, after a prolonged period of prednisone or prednisolone therapy, by the daily determination of urinary 17-hydroxycorticoids. All 25 patients were treated with prednisone or prednisolone according to various dosage schedules. During the treatment they all received a weekly intramuscular injection of 20 I. U. of corticotropin. Eleven patients had rheumatoid arthritis, 5 had acute rheumatic fever, 1 had infectious mononucleosis, 1 had ulcerative colitis, and 7 had bronchial asthma. Prior to hormone administration the adrenocortical function of the patients was assumed to be normal.

The author found that adrenocortical hyporesponsiveness to stress is frequent after prolonged treatment with prednisone or prednisolone, as shown by the low 17-hydroxycorticoid excretion after corticotropin stimulation. This hypofunction of the adrenals may persist for months after corticoid therapy has been stopped, and situations of stress, such as severe infection and major operation, may prove fatal because of acute adrenal insufficiency. Weekly injections of corticotropin during prolonged prednisone or prednisolone therapy do not seem to prevent this adrenal hyporesponsiveness, and a few injections of corticotropin at the end of the treatment are not sufficient to prevent this adrenocortical insufficiency. The author recommends that each series of treatment with prednisone or prednisolone be terminated by giving corticotropin for 5 or 7 days together with prednisone or prednisolone in decreasing doses and then administering corticotropin alone for 3 days. This seems to reduce the risk of hypocorticalism.

SURGERY

Surgical Ascariasis in Children: A Review of 50 Cases. N. Fernando. J. Trop. Pediat. 4:61-70 (Sept.) 1958 [New Orleans].

Obstruction has been the commonest surgical complication of ascariasis, the condition usually commencing with vomiting, often after the administration of a vermifuge. In the 50 cases reviewed, 28 of the children had been given a vermifuge a few days prior to admission. Associated with the vomiting was colicky abdominal pain, mild at the onset but gradually increasing in severity and localized to the umbilicus. The child often vomited roundworms and had constipation, and in the more advanced cases there was abdominal distention with visible peristalsis. An ill-defined sausage-shaped mass lying transversely across the lower abdomen, more often to the right, was found. In the majority of these malnourished children the worms could be palpated through the abdominal wall, and the lump of worms was often disclosed at rectal examination.

That obstruction is at least partly mechanical is shown by the longitudinal disposition of the worms along the length of the intestine, twisted very much in the fashion of ropes. The worms, whose natural habitat is the upper part of the small intestine, may partially or completely obstruct the lumen of the intestine, may vary from a few to several hundreds in number, are often twisted tightly upon themselves, and may thus be propelled onwards along the intestine like a sausage or foreign body. The obstruction may be partly due to spasm of the intestinal muscles, caused by the irritation and reaction of the chitin from the outer covering of the worm's body on the intestinal mucosa of the host, or the introduction of a purgative or vermifuge may cause the worms to secrete a toxic fluid which will initiate the spasm. Although rare, intussusception can be caused by the roundworm, and 4 such examples were encountered in the present series. Volvulus caused by the Ascaris parasites is rare and often fatal, 3 such cases being described in this series. In acute obstruction with peritonitis at operation, a perforation with ascarides in the peritoneal cavity is frequently found. However, no perforations were found associated with obstruction in this series, although a search was made in 4 cases. In the remaining 24 cases a perforation was found in either the appendix, the jejunum, or the ileum. It is of note that many examples have been reported where no perforations were detected, although live roundworms were found in the peritoneal cavity.

The presence of an Ascaris infection in the various organs produces no pathognomonic pattern. Since the small intestine is the habitat of ascarides, the commonest symptoms are referrable to this viscus and vary from vague epigastric distress, nausea, or vomiting to the severest excruciating abdominal pain of perforation or obstruction. There may be associated systemic manifestations, such as anemia, fever, malnutrition, anorexia, lassitude, insomnia, urticaria, headache, and, rarely, convulsions. The diagnosis depends on the identification of the ova or the worms in the feces. Two methods are commonly employed in the treatment of obstructions: (1) manual disengagement of the Ascaris bolus without enterotomy, and milking the worms into the cecum by gentle manipulation; and (2) enterotomy with evacuation.

Tracheotomy for Treatment of Postoperative Respiratory Insufficiency. J. Wassner and H. L'Allemand. Chirurg 29:342-345 (Aug.) 1958 (In German) [Berlin].

The authors report on 32 surgical patients on whom tracheotomy was performed to prevent postoperative respiratory insufficiency or to combat manifest respiratory acidosis. Of the 32 patients, 12 had injuries of the cranium and brain, 5 had been operated on for cranial injuries, 3 had operations on the neck, 1 had an abdominal operation, 9 had undergone thoracic surgery, and 2 had tetanus. Eighteen patients died; death resulted from the primary disease in 14, tracheotomy was performed too late on 2, and 2 were beyond help. Fourteen patients survived. These data show the high incidence of respiratory insufficiency, particularly after injuries of the cranium and brain, in which unconsciousness and a deficient peripheral circulation resulting from impairment of the brain stem favor the development of pneumonia.

Respiratory insufficiency is always a danger to be kept in mind when additional damage is sustained by lungs already handicapped by emphysema, asthma, or the rigidity of the thorax in older patients. Such additional respiratory embarrassment consists of loss of mobility of the diaphragm, painful trauma of the thorax, serial rib fractures, or unilateral and bilateral pneumonia after cranial trauma and barbituric acic poisoning. Rest in bed as such may bring on this condition in patients with asthmatic bronchitis. Tracheotomy should be considered in all patients in whom the occurrence of respiratory insufficiency is suspected. When performed too early in doubtful cases, tracheotomy will not be harmful. Indications for tracheotomy depend on clinical experience rather than on special laboratory reports. The authors are convinced that the number of surgical patients who may be helped by tracheotomy is not small. In certain cases in which tracheotomy alone is insufficient, it should be supplemented with artificial respiration.

Prognosis in Patients with Carcinoma of the Stomach. H. Denck and F. Helmer. Chirurg 29:289-294 (July) 1958 (In German) [Berlin].

The authors report on 1,429 patients with carcinoma of the stomach who were admitted to the second surgical clinic of the University of Vienna between 1933 and 1955. The tumor was located in the fundus or at the cardia in 25.4% of these patients. It was possible to perform resection in 43.2%. Sixty-five per cent of the patients with carcinoma of the antrum had operable lesions as compared with only 44% of those with carcinoma of the body of the stomach and 39% of those with high location of the tumor. The duration of the disease and the age of the patient at the time of the operation had no effect on the operability. The primary operative mortality rate within the first 4 postoperative weeks was 21.5%, with 16.8% after partial resection according to Billroth 1 and 2 operations, 33.6% after total gastrectomy, and 32.5% after resection of the cardia. The operative mortality rate in the patients between the ages of 20 and 39 years was 7.4%; in those between the ages of 40 and 59 years it was 16.3%; and in those between the ages of 60 and 80 years it was 27.2%. The operative mortality rate was 14.3% in patients with carcinoma of the antrum, 22% in those with carcinoma of the body of the stomach, 33.5% in those with carcinoma of the cardia, and 31.5% in those in whom the entire stomach was involved. These figures represent the average for a 22-year period. Since 1951, as a result of the use of antibiotics and modern methods of combating shock, the primary operative mortality rate was reduced to 11% after Billroth 1 and 2 resections, to 29% after total gastrectomy, and to 23% after resection of the cardia.

Of 463 patients who were discharged after radical gastric resection, 43 were lost to follow-up; 67.5% of the remaining 420 patients were still alive after 1 year, 46% after 2 years, and 36% after 3 years, while the 5-year survival rate was 28%. The 5-year cure rate in all the patients with carcinoma of the stomach admitted to the clinic was 8.5%. The life expectancy thus can be extended by surgical treatment to 5 years or longer for hardly 10% of the patients. The term "wide resection" was applied to a resection area in which the tumor was at a distance of more than 3 cm. from both the resection margins (histologically), and the term "limited resection" was used for other resection areas. Three years after a wide resection, 40% of the patients were still alive, and 32.5% were alive after 5 years; the corresponding figures for the limited resection were 28 and 19% respectively. Consequently, the broadest possible resection in healthy tissue is required.

In contrast to the general assumption that the prognosis is particularly unfavorable in young patients with carcinoma, the survival time was not shorter among younger patients who underwent resection than among those of more advanced age. Although the chances for a permanent cure are becoming better after a 5-year survival, the possibility of recurrence of carcinoma still remains even after a longer postoperative interval, and several such cases were observed. The higher mortality rate among patients with a shorter preoperative duration of their disease than among those with a longer duration does not suggest a better prognosis for a patient with carcinoma of long preoperative duration; rather the prognosis is better for one with a slowly growing carcinoma for which he may consult a surgeon only late. A 5-year survival was obtained by 26% of those who underwent resection for carcinoma of the antrum, by 37% of those with resection for carcinoma of the body of the stomach, and by only 13% of those with resection for carcinoma of the cardia. The more favorable prognosis in patients with carcinoma of the body of the stomach appeared to be statistically significant. The prognosis also appeared significantly more favorable in patients with carcinoma of the polypoid-cauliflower types than in those with infiltrating tumors. The life expectancy was considerably reduced in patients with lymph node metastases, even if it seemed that macroscopically the metastases were radically removed. Routine cytostatic treatment after radical surgical intervention and cytostatic therapy after intentionally performed palliative resection in selected patients are recommended in order to improve the results of surgical treatment and with these the prognosis for those with carcinoma of the stomach.

Problems of Acute Cardiac Arrest and Its Treatment. K. Spohn and E. Kolb. Chirurg 29:346-352 (Aug.) 1958 (In German) [Berlin].

Cardiac arrest occurred in 5 of 15,521 patients operated on at the surgical clinic of the University of Heidelberg in 1956 and 1957, i. e., an incidence of 0.032%, or 1 case of cardiac arrest in 3,104 surgical interventions. Of the 5 patients, 3 were men, between the ages of 31 and 57 years, operated on for bronchial carcinoma, stenosis of the aortic valves, and hydrops of the gallbladder, respectively, and 2 were women, aged 51 and 56 years, operated on for benign pyloric stenosis and cancer of the breast respectively. The man with aortic stenosis and the 2 women died.

In the first male patient, in whom cardiac arrest occurred twice at short intervals in the course of pneumonectomy for bronchial carcinoma, electrical defibrillation was successful both times with the first electrical impulse. Spontaneous rhythmic action with sufficient performance was immediately restored. Reflexes originating in the hilus were the main cause of ventricular fibrillation, and the favorable course resulted from the early diagnosis of the cardiac arrest in the open thorax and its rational treatment. The second male patient died in the operating room; there was extreme hypertrophy and also dilatation of the left ventricle, and its blood perfusion was deficient due to the severe aortic stenosis and inadequate coronary circulation. Electrical defibrillation became effective only with the third electrical impulse, but the resulting spontaneous action remained insufficient because of the high degree of hypoxia of the myocardium caused by the intracardiac manipulation and temporary obturation of the aortic valve by the surgical instruments. In the third male patient fibrillation occurred before the operation was started. Some time elapsed before the diagnosis was made and the heart was exposed. Hypoxia had developed in the myocardium, and defibrillation was successful only after several electrical impulses and after intensive intrapericardial massage. The favorable course, despite the relatively long duration of ventricular fibrillation in this 31-year-old patient, was explained by the predominantly functional factors which elicited the arrest.

In the first female patient who underwent gastrectomy, treatment of cardiac arrest consisted exclusively of transdiaphragmatic cardiac massage. Action of the heart was restored by a mechanical stimulus (the clamping of a vessel onto the diaphragm), suggesting hyperexcitability of the autonomic nervous system; the presence of an asystole was assumed. Pulling on the ligamentum hepatogastricum, and on the mesentery very likely, were the reflex-eliciting events, since the arrest immediately followed these manipulations. In the second female patient an initial total atrioventricular dissociation with insufficient ventricular performance turned into asystole. Intravenous administration of arterenol and epinephrine was ineffective. An attempt at transthoracic administration of electrical impulses failed. Only then were thoracotomy and cardiac massage performed, but the asystole no longer responded to therapy and the patient died.

These observations confirm the experiences of other workers that ventricular fibrillation can be controlled easier than asystole. Defibrillation was possible in all 3 patients with ventricular fibrillation, and morphologic reasons were responsible in 1 of them in whom the restored spontaneous action remained insufficient. Of the 2 patients with asystole, circulation could be restored in only 1, but interruption of the cerebral circulation, although of short duration, with the resulting severe irreversible impairment, caused the death of this 56-year-old patient.

NEUROLOGY & PSYCHIATRY

Encephalitis Caused by Asian Influenza. D. Furtado. Rev. neurol. 98:192-205 (No. 3) 1958 (In French) [Paris].

The author reports the case of a 21-year-old soldier who served at an air force base near Lisbon, Portugal, where the entire military personnel had been attacked by an epidemic of Asian influenza. This soldier, like all his comrades, had fever, cough, and catarrhal symptoms at the onset of his illness, but from the onset he also had a marked disturbance of consciousness and spasms of the muscles acting on the jaws. He had 2 generalized convulsions on the second day of illness and was admitted to hospital in status epilepticus. His blood pressure was somewhat low, and he sweated profusely. The extremities were flaccid; the reflexes of the upper extremities were weak, and those of the lower extremities were abolished. There was papillary edema of the right eye. Auscultation revealed severe bronchitis. Treatment with phenobarbital, chlorpromazine (Largactil), and tetracycline was instituted, and lumbar puncture was performed. The next day the patient had no convulsions but was in stupor. The temperature which was 39.5 C (103 F) at onset remained high, and the bronchitis became worse. On the 5th day the stupor deepened, the temperature rose to 40 C (104 F), and death occurred after another epileptic attack.

Autopsy on this patient revealed a hemorrhagic tracheobronchitis, diffuse foci of hemorrhagic bronchopneumonia, and some hemorrhagic foci in the ventricular septum of the heart. Microscopic examination of the central nervous system showed lesions in the main portion of the brain, particularly in the protuberance and in the central nuclei, and less severe lesions in the cerebral cortex and the cerebellum. These lesions consisted of dilatation and congestion of all the vessels, including also the capillaries. Hemorrhagic foci were observed in the parenchyma adjacent to the vessels. The vessel walls were inflamed, and there was infiltration of the Virchow spaces and perivascular edema. The ganglion cells and nerve fibers were affected. There was also extensive infiltration by mononuclear, hematogenous, and glial cells. The leptomeninges were congested and inflamed.

There was no biological proof that Asian influenza had caused this patient's encephalitis, since the virus had not been isolated from him. Yet the clinical presumption was extremely strong, since the patient belonged to an epidemic center with several hundred cases and the Asian variety of influenza, type A, virus had been isolated from some of the patients. The autopsy findings in this patient of hemorrhagic tracheobronchitis and small diffuse foci of bronchopneumonia with a tendency to hemorrhage were exactly the same as in other patients who had died of the influenza. The conclusion that the case was one of severe influenza associated with diffuse and fatal encephalitis, therefore, seemed to be justified. The extensive and early involvement of the nervous system in this patient is suggestive of a direct attack of the influenza virus on this system, similar to that observed in patients with Japanese B encephalitis, rather than of an allergic process so often held responsible for such cases.

Negative Bacteriological and Serologic Results on Reexamination of Problem of Mycobacterial Etiology of Multiple Sclerosis. H. Bauer, K. Bonitz and V. A. Salchow. Medizinische, No. 29/30, pp. 1128-1132 (July 26) 1958 (In German) [Stuttgart, Germany].

In an attempt to reexamine the concept that multiple sclerosis is a mycobacterial disease, the authors carried out a bacterioscopic study for acid-fast bacteria in the cerebrospinal fluid obtained from 17 patients with multiple sclerosis. The precipitate obtained by centrifugation of the cerebrospinal fluid of these patients was used for culture experiments on various mediums and also for inoculation into guinea pigs. In none of these patients was it possible to demonstrate mycobacteria pathogenic to man or animals or saprophytic mycobacteria. In 2 specimens of cerebrospinal fluid, rod-shaped acid-fast structures were observed microscopically, but culture and animal experiments carried out with these specimens gave negative results.

Serologic studies, including complement-fixation reaction, flocculation reaction, hemagglutination, and hemolysis, were performed on 79 persons, 58 of whom had multiple sclerosis and 21 served as controls. The evaluation of the combined results of these studies with regard to tuberculosis revealed positive findings in 7 of the 58 patients, doubtful findings in 7 others, variable findings in 3, and negative findings in 41. Findings were positive in 1 of the 21 control persons, doubtful in 2, and negative in 18. The absolute frequency of positive and doubtful results obtained in patients with multiple sclerosis and the comparative results obtained in control persons do not permit drawing conclusions concerning a mycobacterial causation of multiple sclerosis.

Further Studies of an Epidemic of Exanthem Associated with Aseptic Meningitis. D. A. J. Tyrrell, R. R. Lane and B. Snell. Quart. J. Med. 27:323-333 (July) 1958 [London].

The authors report an epidemic of a febrile disease with headache, which involved 85 patients seen between September and November, 1956, in a practice covering about 3,500 persons in a mixed mining and rural area near Sheffield, England. There were only 8 adult patients, and nearly all the others were children, less than 10 years of age; parents and children were affected in 12 families. Many patients had a maculopapular rash, lymphadenopathy, aseptic meningitis, and lesions of the buccal membrane, either separately or in combination. Vomiting was a common initial symptom, and some adults complained of myalgia. The disease was benign, but convalescence was sometimes rather long. Thirty-three strains of the virus were isolated, and rising antibody titers were revealed by 3 separate methods in 10 of 14 patients. Similar studies of control patients gave negative results. The virus was associated with all forms of the disease and probably caused it. The isolated strains of the virus were of identical type and were related to Coxsackie, group A, viruses and enteric cytopathogenic human orphan (ECHO), type 9, virus. The same virus was recovered in similar cases in many parts of the Western world at about the same time. The authors have proposed the term "benign exanthematous virus meningitis" for this syndrome.

Influence of Temporal Lobectomy on the Mental Condition of Patients with Psychomotor Epilepsy. T. Alajouanine, J. Nehlil and R. Houdrat. Rev. neurol. 98:165-171 (No. 3) 1958 (In French) [Paris].

The authors report on 22 patients with psychomotor epilepsy who underwent temporal lobectomy performed with the aid of electrocorticography; the pole of the temporal lobe was removed and the excision extended in depth to the cornu Ammonis and, if possible, to the amygdaloid nucleus. In 18 of the 22 patients the psychomotor epilepsy was associated with mental disorders; 3 of these had mental debility and were, therefore, excluded; of the remaining 15, 7 had severe mental disturbances, and 8 had minor mental disturbances. The 7 patients with severe mental disturbances were divided into 2 groups, one including 4 patients with manifestations of depression and the other including 3 patients with severe character changes associated with violent impulsion. Of the 4 patients with depression, the manifestations in 3 were not improved by the operation, but in 1 the depressive tendency was considerably improved; the irritable and unbearable patient became quiet and euphoric and appeared to be surprised himself that he had been impatient and depressed; he was able to resume his activities. The patients with severe character changes associated with violent impulsion were those who benefited most from the operation. One of them no longer had the compulsive urge to chastise the interrogator or to take possession of a car and drive away at maximum speed. Another who had constantly terrorized his parents and siblings with his persecution complex and suicide threats was completely transformed; he was quiet and able to work like a normal person. A child whose compulsive urges had led to acts of violence against his family and schoolmates was able to lead a normal life within the family. The 8 patients with minor mental disturbances underwent temporal lobectomy not for their mental troubles but for their refractory psychomotor seizures. The seizures of these patients improved considerably, and so did their psychic behavior. Although there was no strict parallelism in all the 15 patients between the effect of the lobectomy on the psychomotor seizures and on the associated mental disturbances, as a rule those patients whose psychomotor seizures were most favorably influenced by the operation also showed the most definite mental transformation. These observations suggest that in psychomotor epilepsy severe mental disturbances are a strong indication for surgical treatment.

First Poliovirus Isolations Done in Hawaii: Preliminary Report. C. K. S. Yuen, W. H. Civin and P. Y. Tamura. Hawaii M. J. 17:537-538 (July-Aug.) 1958 [Honolulu].

The authors report on 6 boys and 7 girls, between the ages of 9 months and 5 years, in 12 of whom a diagnosis of paralytic poliomyelitis and in 1 of "aseptic meningitis" was made clinically. Of the 13 patients, 8 had not been vaccinated; 1 had received 1 Salk vaccine injection, 1 had received 2 injections, and 3 had received 3 injections. Type 1 poliomyelitis virus was isolated with the aid of cell cultures at the Queen's Hospital tissue culture laboratory in Honolulu from the stools of all 13 patients. The clinical diagnosis of poliomyelitis was thus confirmed by isolation of the virus.

Cerebrospinal Fluid Neuraminic Acid Deficiency in Schizophrenia. S. Bogoch. A. M. A. Arch. Neurol. & Psychiat. 80:221-227 (Aug.) 1958 [Chicago].

Neuraminic acid is a normal constituent of the gray matter of the brain, in which it occurs in combination with carbohydrate and lipid substances in the form of a macromolecular brain ganglioside. The authors studied the presence and the concentration of neuraminic acid in the cerebrospinal fluid obtained in routine diagnostic and anesthetic lumbar punctures from 195 patients, including 29, between the ages of 20 and 63 years, with schizophrenia, 19 adult mental patients without schizophrenia, and 147 patients in a general hospital. Seventy-two of the 147 patients were children less than 7 years of age, 29 were children between the ages of 7 and 15 years, and 46 were adults. The method employed for the determination of neuraminic acid in the cerebrospinal fluid obtained from these patients is described, with the precautions to be observed. The mean neuraminic acid content of the cerebrospinal fluid obtained from patients with schizophrenia was considerably below that obtained from adults without schizophrenia and comparable only to values found in some children less than 7 years of age.

The presence of neuraminic acid in the cerebrospinal fluid, its association with the proteins of this fluid, and the observed variations in concentration suggest that there may be, in addition to the classical concept of a fixed-brain barrier function of brain ganglioside, a circulating component associated with antibody functions. The tendency for the concentration of neuraminic acid in the cerebrospinal fluid to increase with age in man suggests that this substance may be involved in maturation processes in the nervous system. The failure of chemical maturation shown by the schizophrenic patients would correlate meaningfully with clinical evidence showing a failure in psychological maturation. Thus, if the function of the barrier-antibody system is the maintenance of a selective environment for the brain, then the failure of this system could account for the disorganization which is manifest in the psychotic state. The possession of an inadequately developed barrier-antibody system would represent a specific vulnerability to psychosis. In addition to experiments designed to test barrier functions in patients, it will be of some interest to determine the effect of the administration of neuraminic acid itself and of neuraminic-acid-containing substances on psychotic patients.

GYNECOLOGY & OBSTETRICS

Early Diagnosis of Tumors with Particular Reference to Carcinoma of the Uterus. A. P. M. Cappa. Minerva med. 49:2200-2219 (June 2) 1958 (In Italian) [Turin, Italy].

Vaginal and cervical smears for the purpose of detecting carcinoma of the cervix were taken routinely on 712 women, who were employed in 2 factories. Smears were stained by the methods of Papanicolaou, Feulgen, and Unna-Pappenheim. Cytological examination was followed by karyological, and the latter by circular biopsy if the repeated findings of the immediately preceding method were suspicious or positive. Circular biopsy, which was done on 51 women, confirmed carcinoma of the cervix in 20 women and left 3 suspicious cases unresolved. Intraepithelial carcinoma was present in 6 patients, early invasive carcinoma in 4 and invasive carcinoma in 10. It would have not been possible to detect carcinoma in 8 patients on the basis of the clinical findings alone. Positive findings by cytological and karyological methods were subsequently reversed by histological method, which thus gave negative response for carcinoma in 31 patients. However, negative findings by cytological and karyological methods were subsequently reversed by histological method, which gave positive interpretation for carcinoma in 2 patients. The average age of the patients with preinvasive and early invasive carcinoma was 37.9 years and that of the patients with invasive carcinoma was 49.8 years.

PEDIATRICS

Is Interstitial Plasma-Cell Pneumonia Caused by One of the Adenoviruses? O. Vivell and G. Lips. Ztschr. Kinderh. 81:181-182 (No. 2) 1958 (In German) [Berlin].

Morphologically identical changes in the form of inclusion bodies were observed in the pharyngeal epithelium in patients with "colds," presumably caused by adenoviruses, and in young infants with interstitial plasma-cell pneumonia. It was suggested that there might be an etiological connection between these 2 diseases. A common complement-fixation antigen is one of several characteristics of the adenoviruses. Since a complement-fixation test was available also for interstitial infantile pneumonia, the authors investigated whether the cause of interstitial plasma-cell pneumonia in infants might be related to the adenoviruses. They did not find antibodies against adenoviruses in 17 infants with interstitial plasma-cell pneumonia, who had high complement-fixation titers against a pulmonary antigen from a fatal case of interstitial pneumonia. Only 3 of 23 patients, with antibody titers in the adenovirus complement-fixation test, had a positive complement-fixation test also for interstitial plasma-cell pneumonia. Of 29 children in a children's home in which interstitial pneumonia was endemic, 7 had positive reactions to interstitial pneumonia and 8 to adenoviruses. Only one child had positive reactions to both. The authors conclude that the cause of interstitiial plasma-cell pneumonia in infants does not belong to the group of adenoviruses.

Cardiac Infarction in a Fetus. D. Schuler. Arch. franç. pédiat. 15:647-652 (No. 5) 1958 (In French) [Paris].

The author reports the case of a hemorrhagic infarct of the myocardium in a fetus. The mother was in labor for 3 hours when admitted to the obstetric clinic of the University in Budapest, Hungary. She had hypertension, edema, and albuminuria. Examination revealed 2 fetuses, one in vertex presentation and the other in transverse presentation. Intrauterine death had occurred in the latter. The living fetus was delivered spontaneously. Ten minutes later an artificial rupture of the bag of the dead fetus was carried out, a podalic version was done, the fetus was extracted, and autopsy was performed. The body of the dead fetus was covered by a sebaceous coat. Punctiform hemorrhages were observed at the level of the portion of the pleura lining the upper lobe of the left lung. The heart was of grayish-red color and was somewhat flaccid. At the anterior surface of the left ventricle and encroaching on about half of its posterior surface, there was a definitely demarcated area of more firm consistency and dark red color, which projected by a few millimeters into the anterior surface of the right ventricle. A similar area formed a margin at the anterior border of the interventricular septum. The same discoloration also was observed at the apex of the heart, and it continued toward the base of the heart, ending at a distance of about 1 cm. on the side of the atrioventricular groove. These changes were perceptible throughout the entire thickness of the myocardium, with the exception of some uninvolved areas at the level of the left ventricle and of a subendocardial layer. Some punctiform hemorrhages located under the epicardium were observed in the right ventricle and on the posterior surface of the left ventricle. A hemorrhage, the size of a finger pad, was observed adjacent to the atrioventricular branch of the left coronary artery, in the posterior portion of the left ventricle and next to it. There were no other abnormal alterations of the heart; the coronary arteries particularly were normal. A hemorrhage, the size of an infant's fist, was observed under the dura mater at the level of the occipital and temporal lobes. There was a rupture of the vena cerebri magna (vena galeni) and a tear in the dura mater covering the left portion of the cerebellum. These findings suggested that the myocardial infarction was the result of a coronary spasm, which itself was elicited by trauma of the central nervous system and by toxemia.

Staphylococcus Empyema in Children. C. C. J. Sia and S. C. Brainard. Hawaii M. J. 17:339-344 (March-April) 1958 [Honolulu].

The authors report on 8 children, between the ages of 3 weeks and 2 years, who were admitted to the Kauikeolani Children's Hospital in Honolulu for empyema. Staphylococcus pyogenes var. aureus was isolated from the pleural fluid of these patients. Most of them had a history of infection, such as measles or upper respiratory disease, for which they had been given penicillin and broad-spectrum antibiotics. A few days later there was usually a sudden spike in fever, with dyspnea, and the patients appeared toxic; cyanosis, dyspnea, and shock were present on admission of the 3-week-old patient. All the patients were severely ill on admission and had grunting respirations, poor color, and temperatures usually above 102 F (39 C). Chest findings were those of a consolidating process involving one or more lobes of the lungs, with dulness and diminished breath sounds. Paralytic ileus was a common finding after hospitalization. Leukocytosis varied from 17,000 to 35,000 leukocytes per cubic millimeter, with a "shift to the left" in all the patients.

Medical treatment consisted of administration of erythromycin, chloramphenicol, novobiocin, and large doses of aqueous penicillin. Combinations of the 4 drugs were generally selected. Oxygen and intravenously administered fluids were given. Gastric decompression was required in the youngest infant to combat the paralytic ileus. General supportive measures included blood transfusion, antipyretic therapy, and positioning the patient on the involved side. Needle aspirations of the lung were done from 1 to 5 times. The amount of fluid removed varied from a few to 70 cc. Closed drainage was performed in 3 patients, and open rib resection and drainage in 2. The 3-week-old infant had a fulminating course and died. The other 7 patients recovered completely, although complications, such as bronchopleural fistula with pyopneumothorax/ and encapsulated pulmonary abscess, occurred. Hospitalization varied from 17 to 30 days.

Early diagnostic pleural taps and intercostal tube drainage are recommended. An attempt should be made to follow the important principles in the treatment of empyema, with early control of infection, evacuation of the pleural space, and reexpansion of the lung. Frequent chest roentgenograms offer an excellent guide to therapy. Chloramphenicol, erythromycin, and novobiocin are the most effective antibiotics at the present time. With a combined medical and surgical approach, one may hope to have a low mortality and morbidity.

Investigations on the Etiology of Plasma-Cell Pneumonia in Infants. L. Moser. Ztschr. Kinderh. 81: 152-157 (No. 2) 1958 (In German) [Berlin].

The author attempted to isolate the causal factor of interstitial plasma-cell pneumonia in infants by means of tissue culture techniques. Lungs of 12-to-14-day-old chick embryos served as the primary culture medium. The tissue cultures revealed intracellular processes that resembled the nuclei of thrombocytes or of pneumocystis carinii. Observation under the fluorescence microscope revealed that these forms were living cells or parts of cells. It is highly probable that these forms are not the cause of interstitial plasma-cell pneumonia, but rather they are autogenous cell products which, like thrombocytes under certain conditions, play a part in the defense mechanism. In this connection the author mentions reduced thrombocyte counts in rats with vitamin A deficiency and profuse formation of thrombocytes in the endothelial cells of the subcutaneous lymph nodes after the administration of large doses of cod liver oil. Review of the literature revealed that some investigators had called attention to the fact that large doses of vitamins had been given before interstitial plasma-cell pneumonia became evident.

The pneumocystis carinii-like forms are not characteristic for one definite disease entity but have been found in various species of animals and in human cadavers. That interstitial plasma-cell pneumonia is an infectious disease is proved by the fact that it can be transmitted, by the complement-fixation reaction and by the isolation of the virus. The successful tissue culture of the virus and its identification by the complement-fixation and neutralization tests is to be described in a later report, but a photomicrograph in a 1200-fold magnification is reproduced. It is suggested that the virus is a large one and seems to belong to the group that includes the viruses of psittacosis and pneumonitis.

DERMATOLOGY

Evaluation of the Clinical and Serological State of 416 Well Treated Neurosyphilitics After Long Term Observation. F. Kalz and A. Scott. Acta dermat.-venereol. 38:155-167 (No. 2) 1958 (In English) [Stockholm].

The authors report on 490 outpatients with neurosyphilis who were treated at the syphilis clinic of the Royal Victoria Hospital in Montreal, Canada, between 1936 and 1949. Only 74 patients (16%) were lost to observation. Of the remaining 416 patients who were followed for a period ranging from 7 to 20 years, 30 had general paresis, 47 taboparesis, 63 tabes dorsalis, 86 meningovascular neurosyphilis, 156 asymptomatic neurosyphilis, and 34 congenital neurosyphilis. In the first years of the study most of the patients received fever therapy followed by, or combined with, the administration of pentavalent or trivalent arsenic compounds. For a period of 2 years artificial fever therapy in conjunction with the administration of penicillin was used. In the last 10 years, penicillin alone in doses of 10 million units was given routinely, usually 2 or 3 weekly injections of 900,000 units, for a period of 3 to 5 weeks. An attempt was made to assess the prognosis of these well-treated patients with regard to the normalization of the spinal fluid changes, the alteration of the clinical symptoms throughout the observation time, their working capacity, social integration, the causes of death, and their life expectancy.

The average time for normalization of the spinal fluid was 13 years; a positive reaction of the blood to the Wassermann test in low titer persisted in 71 patients and in about 5% the total protein level remained elevated in the absence of any signs of cerebrospinal fluid activity or clinical progression. In all but 3 patients the acute inflammatory phase responded to therapy; 3 patients required retreatment with very large doses of penicillin. The final clinical outcome was satisfactory in 40 (52%) of 77 patients with general paralysis of the insane and taboparesis. The outcome was unsatisfactory in 17 patients (20%), while the remainder showed an initially satisfactory response to treatment, on which psychological disturbances and eventual deterioration were later superimposed. The treatment results in the 110 patients with tabetic symptoms were not satisfactory; while progress of the disease was arrested and the atactic symptoms improved in most of these patients, shooting pains persisted in most of them. The end-results of treatment in the group of patients with meningovascular neurosyphilis were very satisfactory, except in those in whom irreparable brain damage due to cerebral thrombosis had occurred. A considerable number of patients with asymptomatic neurosyphilis had unspecific symptoms including tiredness, loss of appetite, insomnia, and occasional headaches, which could have been easily misinterpreted as neurotic complaints; these symptoms disappeared quickly and permanently after therapy. All patients in this group responded favorably to treatment; in none of them did progression of the disease occur.

Sixty patients died during the follow-up period, but death was attributable to the neurosyphilis in 2 patients only; cardiovascular syphilis led to death in 2 other patients. In the remaining 56 patients, the cause of death was unrelated to the syphilitic infection. Malignancy was the most frequent cause of death, occurring in 18 patients (32%). The life expectancy of the patients with neurosyphilis was not shortened, as compared with that of the general Canadian population. This unexpected finding, contrasting to many other reports, may be explained by the following factors: 1. Severe cases were not included in this group of outpatients, since these patients were transferred directly to institutions. 2. General medical and social care was given to these patients.

UROLOGY

Urogenital Tuberculosis, Diagnosis and Therapy. E. Ljunggren. Nord. med. 59:897-902 (June 26) 1958 (In Swedish) [Stockholm].

For early diagnosis in renal tuberculosis, tubercle bacilli in the urine are looked for by the guinea-pig test and culture in all cases with extragenital tuberculosis. As tubercle bacilluria is usually accompanied by pyuria, only specimens of urine containing pus cells need to be sent for the guinea-pig test. Total and partial nephrectomy are now less commonly recommended because of the good results achieved in renal tuberculosis with chemotherapy. Indications for removal of a tuberculous kidney are cement kidney, tuberculous pyonephrosis, and severely impaired function when there is, as a rule, advanced tuberculosis. The best results of chemotherapy of urogenital tuberculosis are attained with a triple-drug treatment (aminosalicylic acid, streptomycin, and isoniazid), always combined with sanatorium treatment. Triple-drug treatment is now the standard method of treatment. The importance of sanatorium treatment has not been lessened by chemotherapy, and it should last at least a year. In case of intolerance or resistance to one of the preparations, the author has continued with the other two preparations, sometimes adding Conteben. Reversion occurred in the 25 cases in which the triple-drug treatment was applied for at least a year, and the guinea-pig test has been negative after ended treatment. The duration of after-observation has averaged 6½ months; should the guinea-pig test become positive after long-continued chemotherapy, this would usually occur within the first months after ended treatment. Maintained recovery is looked for in the majority of the patients treated. Chemotherapeutics are bacteriostatics; the defense powers of the organism must conquer the invading bacilli, and there is no better method to support this process than sanatorium treatment. With sanatorium care the patient is also under constant control with regard to the toxicity of the agents employed. Furthermore, ureter strictures can occur during chemotherapy and destroy the result of the treatment unless there is timely surgical intervention.

Experiences with the Kolff Twin Coil Artificial Kidney. J. H. Holmes, O. G. Stonington, P. Van Schoonhoven, T. W. Richey and Y. Takeda. J. Urol. 80:102-109 (Aug.) 1958 [Baltimore].

The authors report on 93 dialyses performed with the Kolff twin-cell artificial kidney on 62 patients at the University of Colorado School of Medicine from August, 1956, to August, 1957. The oldest patient treated by dialysis was 84 years old, and the youngest was 3½. Of 22 patients with renal failure due to chronic renal disease, 11 died, and 11 were discharged with improvement. The average age of those who died was 42 years and of those who survived 35. Of 23 patients with acute renal failure, 13 died, and 10 survived. The average age of those who survived was 42 years and of those who died 47. Eight patients were dialyzed for acute renal failure due to toxins. Of these, 7 survived, and 1 died. Of 9 patients with barbiturate poisoning, 8 survived, and 1 died of respiratory failure. Dialysis produced prompt and excellent results in most of the patients. Two patients who were each dialyzed 3 times survived. Two patients were dialyzed 5 times, and in both of them the renal lesion at autopsy was considered irreversible. Multiple dialyses are clinically feasible, and there is no increased risk. The principal indications for dialysis are uremia, electrolyte and fluid imbalance, edema, hyperpotassemia, and intoxication with diffusible toxins. Hemodialysis has been lifesaving in many cases, but the procedure should be limited to major medical centers which have sufficient personnel and a large experience.

Atypical Acute Nephritis: Clinical Observations in Several Cases. E. Hansen. Ugesk. læger 120:908-913 (July 10) 1958 (In Danish) [Copenhagen].

The 7 cases of acute nephritis with rapid and benign course described, in 5 men and 2 women, aged from 22 to 52 years, were distinguished from the usual acute glomerulonephritis in that hematuria, edema, and hypertension were absent or slight, while the clinical picture was dominated by a marked but transient albuminuria, pronounced impairment of renal function of apparently the same type as seen in tubular nephropathy, and prolonged polyuria with hyposthenuria and isosthenuria. No relation to any preceding streptococcic infection could be established. The cases are thought to represent a special form of nephritis of unknown etiology. Attention is called to the similarity to the "epidemic nephropathy" reported in Norwegian and Swedish literature.

THERAPEUTICS

The Influence of Anticoagulant Therapy on the Occurrence of Cardiac Rupture and Hemopericardium Following Heart Infarction: I. A Study of 89 Cases of Hemopericardium (81 of Them Cardiac Rupture). S. Aarseth and H. F. Lange. Am. Heart J. 56:250-256 (Aug.) 1958 [St. Louis].

The present study is concerned with 89 (7.3%) cases of hemopericardium found at autopsy in a series of 1,303 patients who died of heart infarction. Of these 5 had hemopericardium without rupture, and 3 had rupture of the ascending aorta, while the remaining 81 cases had myocardial rupture. The 41 men were aged 41 to 86 years with a mean of 68.5 years, the 48 women ranging in age from 55 to 90 years with a mean age of 72.5 years. The greatest number of instances of hemopericardium with myocardial or aortic rupture were found in the 60-to-79-year age group, the males predominating in the under 60 group, and a greater number of females being present in the group past the age of 80. Twenty-nine patients had a history of previous angina pectoris, 3 had had previous infarctions, 46 had not had symptoms of angina pectoris, and in 8 cases adequate information was not obtained. Hypertension was not uncommon, 33 patients having systolic pressures in excess of 160 mm. Hg and 20 having diastolic pressures above 100 mm. Hg. Aortic stenosis was present in 6 patients, 1 of whom had mitral stenosis as well, syphilitic aortitis in 1, and inveterate syphilis in 1. Serologic tests carried out in 57 of the patients including the 2 mentioned above were negative in all instances. Seven patients (7.6%) had diabetes mellitus.

A study of height-weight ratios did not reveal any particular relation between overweight and cardiac rupture. Anticoagulant therapy was given 33 (37%) of the patients. Hemopericardium without rupture of the heart or aorta was restricted to the latter group, which also included 8 patients who had excessive anticoagulant effect shortly before death. The figures regarding the clinical duration of the infarct, i. e., the interval between infarction and rupture (death), are not considered reliable. More than half the cases died during the first 5 days and about 80% (73) died during the first 10 days, 22 of the 33 receiving anticoagulant therapy dying during a period from the fourth to the ninth day. The rupture was of the left ventricle in all of the 81 cases, and in most instances was near the apex, involving the anterior wall in 43 instances and the posterior wall in 29. The size of the rupture varied from an opening barely admitting a thin probe to tears up to 4 cm. in length. Coronary lesions were demonstrated in several instances as was cardiac hypertrophy. The authors conclude that a fatal hemopericardium may occasionally be caused by anticoagulant therapy in myocardial infarction even in patients within a safe range of anticoagulant effect. A number of cases with excessive anticoagulant effect sustained cardiac rupture, and in these cases an overdose of anticoagulant or excessive anticoagulant effect seems to have precipitated a fatal cardiac rupture.

The Influence of Anticoagulant Therapy on the Occurrence of Cardiac Rupture and Hemopericardium Following Heart Infarction: II. A Controlled Study of a Selected Treated Group Based on 1,044 Autopsies. H. F. Lange and S. Aarseth. Am. Heart. J. 56:257-263 (Aug.) 1958 [St. Louis].

Recent observations indicate that anticoagulant therapy in patients with acute myocardial infarction increases the risk of death from rupture or hemopericardium. The primary series which is comprised of a total of 1,044 autopsied cases included patients receiving anticoagulant therapy as well as patients receiving no anticoagulant therapy. The following categories of cases were excluded in both the treated and untreated groups: (1) patients in whom the infarct had not been diagnosed during life, and who consequently had received no anticoagulant; (2) patients showing old infarction; (3)

patients in whom the exact time of infarction was not definitely known; and (4) patients who died before reaching the therapeutic range of anticoagulant effect. The treated group consisted of 40 men and 29 women, and the untreated group (control) of 38 men and 34 women. The average age for men was 65.3 years in the treated group, and 66.1 in the control group, while the average age for women was 74.8 and 75.5 years respectively. None of the women were less than 60 years of age, the male-female age difference being 9.5 years in the treated group and 9.4 years in the control group. Seventy per cent of the deaths in the treated group and 64% of the deaths in the control group occurred within 20 days after infarction. Although 50% of the patients in the control group died within 5 to 9 days there was a greater variation in the length of survival in the treated group, which was ascribed to the routine discontinuance of anticoagulant therapy after 4 weeks and was attended by an immediate rise in temperature and subsequent death in a number of patients. There was only 1 instance of hemopericardium without rupture. Hemorrhagic fluid with or without fibrin deposits was found in 10 patients in the treated group (14.5%), and in 4 patients in the control group (5.5%), while serous fluid was found in 8 patients (11.6%) of the treated group and in 18 patients (25%) of control group. Normal pericardium was noted in 22 (32%) of the treated group and in 31 (43%) of the control group. Intracardiac mural thrombi were found less frequently in the treated group (6%) than in the control group (11%). The incidence of hemopericardium in the treated group was almost twice as large (15 of 69 patients) as in the control group (8 of 72 patients), permitting the conclusion that anticoagulant therapy may contribute to the weakening of the affected area of the myocardium with consequent rupture.

Therapy of Choriocarcinoma and Related Trophoblastic Tumors with Folic Acid and Purine Antagonists. Min Chui Li, R. Hertz and D. M. Bergenstal. New England J. Med. 259:66-74 (July 10) 1958 [Boston].

The authors report their experience with the treatment of 6 men and 5 women suffering from choriocarcinoma or related trophoblastic disease, the diagnosis of which was based on unequivocal histological evidence. The patients, all of whom were hospitalized throughout all periods of active therapy, received either orally or intramuscularly a daily dose for 5 consecutive days of 15 to 25 mg. of methotrexate; 6-mercaptopurine was administered orally in daily doses of 600 to 800 mg. for 5 days. No further therapy was given until all signs of induced toxicity had completely subsided, subsequent courses of 5 days' duration being administered with similar precautions. The most sensitive criterion of therapeutic effort was found to be the level of urinary chorionic gonadotropin. In all 6 women the repeated courses of methotrexate administration were followed by unequivocal evidence of tumor regression and a concomitant drop in gonadotropin excretion. The 5 male patients failed to show any distinct response to methotrexate or 6-mercaptopurine, their clinical status remaining unimproved and x-ray examination revealing no decisive retrogression of the extensive metastases. Only minor fluctuations in the gonadotropin titers were noted, the disease process running an unrelenting course with 4 of the 5 men dying with characteristic manifestations of the primary disease. Procedures aimed at rendering the internal environment of the male host more comparable to that of the female failed to alter the tumor response.

Pharmacology and Clinical Use of Pempidine in the Treatment of Hypertension. M. Harington, P. Kincaid-Smith and M. D. Milne. Lancet 2:6-11 (July 5) 1958 [London].

The authors studied a new drug of the amine, ganglion-blocking type. This drug is 1:2:2:6:6-pentamethyl piperidine. It is known under the common name pempidine, and the name "perolysen" has been proposed. Pempidine is a tertiary amine, a simple derivative of piperidine of empirical formula $C_{10}H_{21}N$. For experimental studies on pempidine the same method was used as for mecamylamine. Thirty-two hypertensive patients without renal failure were given pempidine, and of these 27 received continuous treatment. Observations were made on 2 patients with hypertension complicated by moderate uremia. Twenty-one patients were studied after a single intravenous dose of pempidine. In all except 2 cases the drug was given in a dose of 5 mg. of hydrochloride (4 mg. base). Single oral doses of 5 to 20 mg. of bitartrate (2.5-10 mg. pempidine base) were given to 9 patients. A hypotensive effect was usually observed within an hour after an oral dose. The duration of hypotensive action was 6 to 7 hours after the dose, although the maximal effect lasted for only 1 to 3 hours. In 2 cases after an intravenous dose, and in 3 after a large oral dose, there was a severe fall in blood pressure, and the effect of the drug was prolonged for as long as 24 to 36 hours. One of these patients had severe oliguria which undoubtedly interfered with excretion of the drug. In 24 of the 27 patients who received continuous treatment with pempidine treatment had been continued to the time of this report, for from 2 to 20 weeks (average 10 weeks).

Pempidine is similar in many respects to mecamylamine. Both drugs are rapidly and completely absorbed from the intestine. They readily cross cell memebranes and are concentrated within tissues by intracellular protein-binding, especially to nucleoproteins. The excretion of both drugs is influenced by urinary pH, clearance being decreased in alkaline and slightly increased in acid urine. Several differences make pempidine a potentially more useful drug than mecamylamine. While 25% of mecamylamine is bound to plasma-protein, pempidine is not so bound, and therefore all the drug in plasma is pharmacologically active. Pempidine is excreted more rapidly than mecamylamine. This is advantageous because toxic accumulation of the drug in the body is less likely. In addition, the dosage of pempidine can safely be increased to effective levels more rapidly than that of mecamylamine. Excretion of pempidine is less affected by variation in acid-base balance than that of mecamylamine. The difference between an effective and a toxic concentration is probably greater in the case of pempidine. A steady hypotensive effect can be maintained throughout the day when pempidine is given orally at 5-hour intervals. The dosage of pempidine can be quickly increased, owing to the rapid elimination of the drug.

ANESTHESIA

Single Lung Anesthesia in Surgery. I. S. Zhorov. Khirurgiya 34:11-20 (No. 6) 1958 (In Russian) [Moscow].

Indications for single lung anesthesia are limited. It is employed mainly in total removal of the lung and occasionally in removal of 1 or 2 lobes. Single lung anesthesia has certain advantages over endotracheal anesthesia during operations connected with purulent lung diseases, since it provides the best isolation of the diseased lung from the healthy one and prevents penetration of infected and noninfected masses into the latter. Single lung anesthesia provides sufficient oxygen saturation of the blood. This anesthesia is induced by the block of the main bronchus of the diseased (operated on) lung and by endotracheal anesthesia or by introduction of a tube into the bronchus of the unaffected lung for endobronchial anesthesia. Single lung anesthesia is more complicated than endotracheal, since at times it requires roentgenologic examination besides the physical one. It may be carried out by any experienced anesthesiologist.

Minor Laryngeal Sequelae of Endotracheal Intubation. B. Wolfson. Brit. J. Anaesth. 30:326-332 (July) 1958 [Altrincham, England].

In an attempt to assess the number of minor laryngeal sequelae produced by intubation in the everyday anesthetic practice of a fairly large hospital, the author interviewed between the 2nd and the 8th postoperative day 521 patients who had been operated on with the aid of endotracheal anesthesia at the Western Infirmary in Glasgow, Scotland. The complaints elicited by the interrogation were as follows: Eighty-three patients (15.9%) had a slight sore throat; 13 (2.5%) had a severe sore throat; 17 (3.3%) were hoarse; 2 (0.4%) lost their voices temporarily; and 4 (0.8%) had sore throats and were also hoarse. The complications lasted from 3 hours to 7 days. Fifty-four patients (10.3%) had complications lasting 2 or more days, and 61 patients (11%) had complications lasting less than 2 days. The incidence was affected only by the sex of the patient, being much greater in the female patients. There was a greater incidence also in patients in the prone position than in the supine, lithotomy, Trendelenburg, or lateral positions, but the figures were not statistically significant.

PUBLIC HEALTH

Killed Antituberculous Vaccine—V. D. S. Vaccine (Diffusing Vaccine Salvioli): V. Clinical, Roentgenologic, and Hematological State (in 1956) of Newborn Infants Vaccinated (in 1954-1955) with V. D. S. Who Were Exposed to Tuberculous Infection in the Family. F. Grandi and M. Malossi. Minerva Med. 49:2545-2566 (June 27) 1958 (In Italian) [Turin, Italy].

Forty-three infants, most of whom belonged to families in which at least one member had tuberculous disease, were born at a community maternity center and were vaccinated at birth with diffusing vaccine Salvioli (V. D. S.) during the period 1954-1955. A year later 40 of the infants were examined for the possible presence of tuberculous disease, but none had such disease as established by clinical and roentgenologic examinations. Most of the infants presented positive reaction to Wolmer's tuberculin test. The general state of health was satisfactory, although the infants came from poor homes and most of them were bottle-fed. The erythrocyte sedimentation rate tended, on the average, to reach the upper physiological limits. The white blood cell count varied between 9,200 and 24,800 per cubic millimeter, which values exceed the mean physiological value of 10,000 per cubic millimeter according to Lavergne's formula. The leukocytic formula (differential count) did not deviate significantly from the normal values, with the exception of a slight increase in the eosinophil count. The Velez index, which has a high diagnostic value for excluding tuberculous disease where it is not actually present, was negative in all the children. The Arneth-Cooke formula also presented nonpathological values. Vaccination of newborn infants with the killed antituberculous vaccine, V. D. S., has thus been shown to be an innocuous procedure, even if administered to feeble infants living in an environment where they are highly exposed to Mycobacterium tuberculosis. It is not necessary to put the children in preallergic isolation.

Killed Antituberculous Vaccine—V. D. S. Vaccine (Diffusing Vaccine Salvioli): VI. Reexamination (in 1957) a Year After Initial Examination (in 1956) of a Group of Infants Who Were Vaccinated at Birth with V. D. S. and Exposed to Tuberculous Infection in the Family. F. Grandi and M. Malossi. Minerva med. 49:2566-2575 (June 27) 1958 (In Italian) [Turin, Italy].

In 1957 a second clinical and roentgenologic inspection was made a year after the initial study in a group of 30 infants who were vaccinated at birth with diffusing vaccine Salvioli (V. D. S.). Tuberculous disease was known to exist in the homes of 20 infants and was presumed to be present in the homes of the others. The leukocytic formula (differential count), Arneth-Cooke formula, Velez index, and Wolmer tuberculin test were investigated in all the infants. All the children but one were free of the clinical symptoms of tuberculous disease. Body weight had increased in 27 infants. Sensitivity to tuberculin, as evidenced by the reaction to the Wolmer test, increased in 8 infants, remained unchanged in 8, and decreased in 13, as compared with the reaction to the test in 1956. The Velez index, which was negative in all but one infant, was, on the average, more negative than the year before.

The primary phase of a tuberculous process of exudative type was established in the one infant who was ill. The disease, which had taken a mild form, was easily controlled and cured with chemotherapy, since there were few local symptoms and the absence of such general symptoms as fever affected the child's well-being and body weight. The case demonstrated the efficacy of the V. D. S. vaccine in mobilizing antibodies for attacking the etiological agent of tuberculosis in infants. The infant was again examined a year after remission of the disease and was found to be healthy. This second examination once again demonstrated the effectiveness of the V. D. S. vaccine in protecting vaccinated infants against tuberculous disease during the first 2 or 3 years of life despite poor economic and hygienic conditions.

Field and Laboratory Studies on Equine Encephalitis. R. F. Feemster, R. E. Wheeler, J. B. Daniels and others. New England J. Med. 259:107-113 (July 17) 1958 [Boston].

Research activities have been carried out in the state of Massachusetts since 1938 to determine the possible reservoirs and vectors of the virus of equine encephalitis. At the time of the outbreak in horses and human beings in 1938 the only known laboratory vectors of the equine viruses were 8 species of mosquitoes belonging to the Aedes genus. In 1941 Hammon and co-workers isolated the western equine virus from free-living mosquitoes of the Culex genus, thus proving that transmission was not restricted to the Aedes genus. In 1943 the same group demonstrated that barnyard fowl could act as reservoirs of the St. Louis and the Western equine-types of encephalitis. In 1953 a total of 146 specimens of blood were obtained from birds shot in the vicinity of Hockomock swamp, which is located near the communities of Easton, West Bridgewater, Bridgewater, Raynham, Tauton, and Norton. In addition, blood specimens from 19 horses were collected. Of the latter group, 1 had antibodies for the eastern virus of equine encephalitis alone, 6 for the western virus alone, and 2 for both. A total of 105 (71.8%) of the 146 birds had no antibodies for the eastern virus, 8 (5.5%) not having been tested for such antibodies, and only the last bird shot in the study yielded the eastern virus by isolation. Twenty (13.7%) of the birds gave evidence of infection with the eastern virus alone, 2 (1.4%) with the western virus alone, and 13 (8.9%) with both.

Late in 1955, after 44 horses had become infected, 4 human cases of equine encephalitis were reported in Boston hospitals, 1 of which was fatal. Four pheasant farms had losses owing to the virus, and 2 pheasants, found ill in the field, yielded the eastern virus. Only 2 of the 356 persons living in close proximity to the Hockomock swamp, from whom blood specimens were taken in 1956, gave positive neutralization tests for the eastern virus, with indexes of 32 and 80 respectively. An additional survey revealed that, of a total of 537 persons with no history of encephalitis, 3 (0.7%) showed low titers of neutralizing antibodies, indicating that inapparent infections with the eastern equine virus in Massachusetts are so infrequent as to be of little significance. Another survey of 152 birds in 1956 revealed 55 birds with evidence of infection with the eastern virus, while 12 had been infected with both the St. Louis and the eastern equine viruses. The eastern virus was isolated from 4 birds; only 4 birds showed antibodies for the St. Louis virus alone. Of the 269 birds studied in the 1957 series, only 12 had antibodies for the eastern virus of equine encephalitis, 9 of them being crows. Four chickens out of 85 tested and 5 turkeys out of 66 tested showed antibodies for the eastern virus. It is of note that 7 out of 39 pigs tested had antibodies for this same virus of equine encephalitis. Culiseta melanura is the mosquito that has been indicated as the vector among birds, and perhaps as the vector from bird to man and horse, while wild birds appear to be the reservoir of the disease for both man and horse.

BOOK REVIEWS

Intestinal Obstruction. By Claude E. Welch, M.D., D.Sci., Clinical Associate in Surgery, Harvard Medical School, Boston. Cloth. $10.50. Pp. 376, with 135 illustrations, drawings by Muriel McLatchie Miller. Year Book Publishers, Inc., 200 E. Illinois St., Chicago, 1958.

From the mass of literature on intestinal obstruction and from his own experiences, the author has presented the salient facts about intestinal obstruction. This monograph is thus a ready reference for interns, residents, and surgeons who are responsible for the care of such patients. In the early chapters, the causative factors, lesions, and pathological physiology are reviewed as an introduction to the clinical management of patients with intestinal obstructions. In the discussion of the diagnosis of intestinal obstruction, it is wisely stated that "although the diagnosis can be made by x-ray, in 90% of the cases strict reliance on this method is unwise." Close cooperation between radiologist and surgeon is necessary to obtain the best result. Although the danger of giving barium to patients with intestinal obstruction is fully discussed, the author is not opposed to giving thin barium or sodium acetrizoate orally in order to locate the site of an obstruction of the small intestine. Intestinal intubation and the general problem of replacement therapy are thoroughly discussed. Because of the danger of intestinal strangulation during prolonged unsuccessful intestinal intubation, the author advises early operation in simple types of obstruction. The major part of the book is devoted to the management of the various types of intestinal obstruction. Each type is discussed from the standpoint of etiology, symptoms, diagnosis, and treatment. The author's surgical technique is well and profusely illustrated. The many causes of postoperative obstruction, diagnosis, and their treatment are reviewed. The book has a provocative chapter on intestinal obstruction and peritonitis. The author is inclined to operate on patients with obstruction in the presence of peritonitis when the generally accepted conservative therapy seems to fail. He supports his views with the excellent results in a small series of patients on whom he carried out the lysis of adhesions, intestinal resection and anastomosis, and enterocolostomy in the presence of peritonitis. This monograph is highly recommended to all medical personnel responsible for the care of patients with acute intestinal obstruction.

Law and Ethics for Doctors, with a Section on General Practice in the National Health Service. By Stephen J. Hadfield, M.A., M.B., B.Chir. With contributed sections on negligence by W. G. Hawkins and the late W. Mair. Superannuation by L. S. Potter, M.D., Ch.B. Income tax by W. Donald, C.A. Cloth. 42 shillings. Pp. 399. Eyre & Spottiswoode (Publishers) Ltd., 15 Bedford St., Strand, London, W. C. 2, England, 1958.

This book describes rather fully many of the obligations imposed on the physicians of England by the National Health Service and related acts. It is clearly a handbook to be used by the physician in England who practices his profession in a somewhat less than free climate of medical enterprise. Of general interest, however, is the description of the Privy Council, the General Medical Council, and the Medical Register. Ethical principles are discussed briefly. For members of the medical profession in the United States this book has little practical value. It is, however, a revealing collection of miscellaneous information which indicates all too clearly the regimentation of medical practice under the National Health Service.

The American Academy of Orthopædic Surgeons Instructional Course Lectures. Volume XIV. Editor: R. Beverly Raney, M.D. Cloth. Pp. 388, with illustrations. J. W. Edwards, Ann Arbor, Mich., 1957.

This new volume presents some of the lectures that were given before the American Academy of Orthopædic Surgeons in February, 1957. It is another excellent book in their annual series. It will be of value as a teaching and reference book on the resident level, but it is perhaps too technical for the medical student. Its great value lies in the completeness with which one facet of a surgical problem is handled. This is particularly true in such articles as Congenital Dysplasia and Dislocation of the Hip in Infancy, Proximal Femoral Osteotomies, and Congenital Pseudoarthrosis of the Tibia. There is a wide range of coverage on conditions of the spine and the upper and lower extremities. Of special note are the articles on local manifestations of systemic diseases, or diseases involving the skeleton, which provide interest to the roentgenologist, the pediatrician, and the internist, as well as to the orthopedist. This volume should be read diligently by every young orthopedist intending to take either part of the specialty board examinations. It should be of value also to the older orthopedist, by keeping him abreast of modern trends in operative or orthopedic surgery. No original work or research is reported; the book is a record of the teachings presented at the annual meeting. The articles on

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

interpretation of pain are nebulous and inclined to give quotations from older authors too much and to show acceptance of their writings with sometimes an implication of finality. The bibliographies after each article are ample, and the authors cover the subjects succinctly and, as a rule, impartially.

Tumors of the Soft Somatic Tissues: A Clinical Treatise. By George T. Pack, M.D., LL.D., F.A.C.S. Associate Professor of Clinical Surgery, Cornell University Medical College, New York, and Irving M. Ariel, M.D., F.A.C.S., Associate Clinical Professor of Surgery, New York Medical College, New York. Cloth. $30. Pp. 820, with 652 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1958.

This comprehensive textbook discusses the clinical management of patients with soft somatic tumors in connective tissues, fat, smooth and striated muscle, fascia, synovia, blood and lymph vessels, and nerve tissues. Each tumor type is discussed, and features that differentiate benign from cancerous growths are presented. The monograph reflects the results of treatment in a group practice during 25 years. It contains six sections: (1) history, classification, incidence, hereditary and congenital occurrence, role of trauma and other etiologic factors, and cancerous evolution of a benign growth; (2) techniques of wide local excision and other details of amputation; (3) treatment of specific tumors and tumor-like or preneoplastic proliferations; (4) sarcomas of infants and children, their treatment and results; (5) the principles of therapy of these tumors in such locations as the neck, abdominal wall, buttocks, and retroperitoneum; and (6) therapeutic results and an analysis of the factors that influence prognosis. The chapters in each section document the subject material presented with a substantial bibliography. The book is well written and illustrated. It presents clearly a large amount of practical information on diagnosis and treatment, including the special techniques of surgery for the many tumors arising in the soft somatic tissues. This information is especially valuable to all surgeons, both in diagnosis and in surgical and radiation treatment. Pathologists also should find this book a good source for information about these tumors.

Pediatric Index: A Guide to Symptomatological Diagnosis and Current Management. By Edwin F. Patton, M.D. Cloth. $13.50. Pp. 639, C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

This book presents an alphabetical listing of all pediatric conditions, normal and abnormal. It is similar to Davison's "Compleat Pediatrician" but more comprehensive. There is no arrangement in body systems or any discussion of disease entities other than the exhaustive listing and correlation of signs and symptoms aimed at assisting in the diagnosis and treatment of all manner of problems of childhood. The material is organized into three sections. The first and largest provides an exhaustive indexing of major signs and symptoms, broken down wherever possible into those found in the infant or the older age group. Minor corroborative or differentiating findings are included, and a suggestive diagnosis is offered. The second section lists abnormal conditions, each with exact information required for a definite diagnosis. Wherever appropriate, a list of conditions to be ruled out is given. The latest or best treatment is then outlined. The third section, dealing with special data and technique, is more meager, and one may wonder why the few techniques given were selected to the exclusion of others. The concise information on electrolyte and fluid adjustment, seizures, and antibiotics in this section is excellent. This book should be considered as a diagnostic reference textbook. The material on poisoning is particularly extensive, and the information on orthopedics goes beyond that found in most pediatric textbooks. Much space is devoted to febrile disorders. The well-differentiated headings, the adequate-sized type, and the multiple cross references facilitate the finding of information. This book is intended as an aid to physicians, experienced or inexperienced, in clarifying obscure pediatric diagnoses, preventing oversight of rare conditions, and providing a guide for treatment.

The Organization and Administration of Physical Education. By Edward F. Voltmer, and Arthur A. Esslinger. Third edition. Cloth. $5. Pp. 558. Appleton-Century-Crofts, Inc., 35 W. 32nd St., New York 1, 1958.

The authors place the emphasis on the education in physical education. Exercise and health are important outcomes, but education for fitness, skill and understanding, and personality and character development is the primary goal. Effective organization and administration of the program facilitates the achievement of this objective. The book is based on a study of current problems in physical education. After delineating the place of physical education in education and outlining aims, the authors emphasize the need for well-defined administrative policies and the means of establishing these. They then show how such policies can be applied in the organization and conduct of the class program in physical education, the intramural sports program, and the program of interscholastic athletics. Equipment and facilities, tests and measurements, budget making and financing, public relations, legal liability, and working with staff members and student leaders are also discussed. Recognizing that school health education may be administered separately from physical education in many school organizations, the authors give it only brief coverage. References are relied on to provide details for those having dual responsibility or concern for school health education. Through extensive revision, the authors have made the material in this new edition more applicable for a wider audience, including teachers and leaders in service as well as those preparing for teaching and administration of physical education.

General Pathology Based on Lectures Delivered at the Sir William Dunn School of Pathology, University of Oxford. Edited by Sir Howard Florey, Professor of Pathology, University of Oxford, Oxford. Second edition. Cloth. $16. Pp. 932, with 344 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1958.

This book is based on a series of lectures in general pathology and bacteriology given to medical students after completion of their physiology and biochemistry courses and just preceding their clinical work. Stress is laid on the fundamental changes that take place in the body in response to injury. Present-day views about the nature of those changes are discussed. An effort is made to stimulate in the mind of the student an experimental outlook for clinical medicine and surgery. This second edition has been revised and rearranged, and additional chapters on thrombosis, metabolic changes after injury, atherosclerosis, and tumors have been added to make the book more complete. Fourteen authors, in addition to the editor, have contributed special chapters. The authors' aims have been well accomplished, and there is excellent coverage of all aspects of general pathology and bacteriology. The altered physiology in anatomic pathological changes is considered in detail. The historical approach is maintained throughout, and a good background is provided for each subject. Experimental evidence is given in many instances, and throughout the book are numerous excellent photographs and drawings, including color plates. The book is well bound, clearly printed, and easy to read. The European spelling of certain words is interesting but not a detraction. The wealth of detail presented may be more than is desired by many students, but it helps to give an interesting, well-rounded approach to the subject. This book can be recommended to medical students, especially those whose interests extend beyond their required courses in pathology.

A Text on Systemic Pathology. Volume 1. Edited by Otto Saphir, M.D., Director, Department of Pathology, Michael Reese Hospital, Chicago. Cloth. $32. Pp. 865, with 818 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1958.

Pathologists and others often need information pertaining to a disease only to find that the available textbooks fail to go into sufficient detail or sketchily outline the correlation of the clinical findings with the pathologic process. This book, the first of two volumes, was written to fill this vacuum. It takes into account at all times the fact that a diseased organ or organ system is not a separate entity but part of the whole organism. In most instances, the description of a pathological entity begins with the first signs and symptoms, continues through the gross, microscopic, and statistical data, and includes postoperative complications. In addition to the editor, contributors include Maurice Lev, Jay J. Gold, and Ira Gore. The excellent continuity makes for easy reading. The material is presented in a manner which makes the book equally valuable to the pathologist and the nonpathologist and represents the authors' first-hand experience with the subjects discussed, including the findings in a number of diseases which they have studied extensively. The literature has been critically evaluated, and an attempt has been made to eliminate some time-honored opinions which do not stand the test of more recent experience. The photographs are excellent. This book would be a valuable addition to the library of any physician.

Advances in Electrocardiography. Edited by Charles E. Kossmann, B.S., M.D., Med.Sc.D., Associate Professor of Medicine, New York University College of Medicine, New York. Cloth. $9.75. Pp. 280, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1958.

This monograph deals with the fundamental advances in electrocardiography made in the period 1946-1956. The editor is assisted by five contributors. The subject matter is discussed under four categories: source of potential, conducting medium, spread of excitation, and recovery and rhythms. Much of the material consists of biochemical, biophysical, and mathematical concepts which form the bases for modern clinical electrocardiography. This portion is written in an interesting manner, is well documented with diagrams and illustrations, and of necessity is not light reading. Other portions deal with fundamental bases of practical electrocardiography and are magnificently presented and illustrated. Of particular note in this latter category are the chapters on intraventricular conduction and electrocardiographic interpretation in congenital heart disease. The purpose of the monograph is to present the most significant advances in the fundamental sciences applied to electrocardiography for the clinician and not to present another textbook on interpretation. The authors have succeeded in their purpose and have fulfilled a great need of the clinician in collecting and correlating the important experimental work from the mountainous mass of published data. This monograph should be in every internist's library.

QUESTIONS AND ANSWERS

ETIOLOGY OF MENTAL DEFICIENCY

To the Editor:—*Please give a summary of the present concept of the relative importance of the various etiological factors in mental deficiency of school-aged children. What is the importance of genetic factors in cases not associated with cerebral palsy?*
Lawrence M. Herman, M.D.
Monterey Park, Calif.

Answer.—It is, perhaps, still helpful to think of the causes of mental deficiency as falling into roughly two large groups—those determined largely by genetic or endogenous factors and those due to exogenous factors related to the environment and its modification during intrauterine or postnatal life. From a clinical standpoint, by far the most types fall into the exogenous group. At the present time this is also the group about which medicine can do much in the way of prevention. Attention to such prenatal factors as infection (via German measles), isoimmunization (Rh factor), and toxemias of pregnancy or pelvic irradiation is most important in prevention. Any perinatal factor leading to hypoxia or intracranial hemorrhage and postnatal factors such as encephalitis (primary or allergic), such toxic substances as lead or drug ingestion, severe emotional deprivation in infancy, and severe repeated or prolonged convulsions are factors that physicians can also do much to control or modify. Genetic factors can be thought of from a clinical point of view as due to single recessive genes or to single dominant genes. The clinical pictures in the former group are usually easily recognized, often because the defect is sharply segregated to a family group. Examples of these conditions would be phenylketonuria and galactosuria, both of which can now be detected in infancy, and much damage to the brain can be prevented by appropriate treatment. Other clinical entities of this group are amaurotic idiocies (Tay Sach group) and lipochondrodystrophy (gargoylism), not modifiable at present by treatment. The clinical entities due to single dominant genes are not always so easily identified because of the frequent occurrence of atypical or incomplete form. Tuberous sclerosis and certain of the dysostoses are examples of this group. Many children who are thought to be mentally retarded because of an inability to cope with school work turn out to be children who are educationally handicapped by various forms of brain damage in the areas concerned with the use of symbols. Careful examination by an experienced neurologist, speech therapist, or child psychiatrist often reveals mixed forms of aphasia, agnosia, and apraxia. The importance of recognizing these clinical conditions is that remedial help can be obtained, usually from a skilled speech therapist. These children are not really mentally retarded, but they are educationally retarded because of their great handicaps in learning via the usual symbolic tools. The IQ as a measure of intellectual potential can vary widely in an individual's lifetime, and a single measurement should not be taken as a complete diagnosis—a practice which is unfortunately rather widespread. Every effort should be made to make a diagnosis of retardation based on etiology, i. e., a medical diagnosis.

MUSCULAR DYSTROPHY

To the Editor:—*An 8-year-old boy who is mentally deficient has developed muscular dystrophy of the pseudohypertrophic type. This disease developed insidiously after a mild case of poliomyelitis in 1955. His history is noncontributory except for a cerebral concussion, in February, 1956, and a large hiatus hernia found at birth. Norethandrolone used empirically in moderate doses apparently increases muscle tone and energy in this child. Please give information concerning the use of this or any other drug helpful in the treatment of this disease. Have any cases of muscular dystrophy in any way correlated with severe head injuries or poliomyelitis been reported?*
George M. Wolverton, M.D., Clarksville, Ind.

Answer.—The child referred to in this question certainly has an unusual complication or collection of neurological conditions—mental deficiency, muscular dystrophy, cerebellar concussion, and poliomyelitis. One certainly must wonder about diagnosis in this case. There is no evidence that muscular dystrophy can in any way be correlated with severe head injuries or that it may develop after poliomyelitis. Were it not for the reported pseudohypertrophy, one would wonder whether his weakness might not be a poliomyelitic residual. No drugs of proved value in muscular dystrophy are available. Vitamins and amino acids have been reported to be of therapeutic value, but controlled studies have failed to confirm this. Norethandrolone should not be given for any prolonged period of time, especially in prepuberal children.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

ITCHING OF THE TONGUE

To the Editor:—*A 9-year-old boy complains of his tongue itching. It is not sore or tender, but he takes his fingers to scratch it and it annoys him greatly. This has occurred on and off for three years. It may last for days at a time, or he may be free of the itch for months; it has occurred in any season. The tongue appears normal or has red raised bumps on it. Antihistamines did not help. Please give advice on this problem.*

M.D., Ohio.

Answer.—Itching of the tongue, if it can occur, must be extremely rare. In experiences over a period of 35 years with patients with allergies, including many who have had itching of the palate, this consultant has never encountered an instance of itching of the tongue. The failure to obtain any relief from antihistamines makes it likely that the complaint is not based on a histamine mediation mechanism. The explanation for this complaint is not obvious, but a trial of a tranquilizer, such as hydroxyzine hydrochloride in 10-mg. doses, is suggested.

LOSS OF SMELL AFTER HEAD INJURY

To the Editor:—*A head injury after an automobile accident has caused the loss of smell and a partial loss of taste. The patient is 6 months old. Will this be a permanent condition?*

J. W. Geiger, M.D., LaSalle, Ill.

Answer.—Loss of smell is not an unusual sequel of head injuries. Fracture of the cribriform plate of the ethmoid bone or hemorrhage at the base of the frontal lobes may cause tearing, crushing, or compressing of the olfactory filaments. With such anosomia there is also some loss of ability to perceive and recognize flavors which involve not only taste but also olfactory sensation. Such loss of smell and impairment of taste is often a permanent condition, especially if there has been tearing of the olfactory filaments, and, if there has been no return of function after six months, it may be presumed to be permanent.

ALOPECIA WITH MULTIPLE SCLEROSIS

To the Editor:—*A 39-year-old man, who has had multiple sclerosis for the past five years, complains of spotty loss of his beard. He does not have evidence of alopecia of the scalp. How often does this condition occur? Is it ever associated with multiple sclerosis?*

K. McMorrow, M.D., Detroit.

Answer.—The probable diagnosis of this condition is alopecia areata, a rather common entity. This may be confined to the bearded area. Its etiology is unknown, but psychosomatic influences seem to be important in its causation and in the precipitation of attacks. Alopecia of this type is nonspecific, but there is no reason why it could not occur in association with multiple sclerosis, since psychiatric complications are not unusual in that disease.

HIATUS HERNIA AND PAROXYSMAL TACHYCARDIA

To the Editor:—*Can hiatus hernia cause paroxysmal tachycardia for 31 years? A 52-year-old man has had paroxysmal attacks of supraventricular tachycardia for 31 years. He is sensitive to quinidine and has been responding well to lanatoside C. But, lately, he has been having very frequent attacks. A fairly thorough examination was done, and the only positive finding was a fairly big, sliding hiatus hernia.*

Antonio D. Talusan, M.D., Baltimore, Md.

Answer.—If the hiatus hernia was as big 31 years ago as it is now, then it is feasible that it may be the cause for the tachycardia, through stimulation of the thoracic sympathetic chain. If so, repair of the hernia would be advisable.

XANTHOMA DIABETICORUM

To the Editor:—*Please advise regarding treatment of xanthoma diabeticorum. A 53-year-old woman has numerous lesions on the posterior aspect of elbows, anterior aspect of both knees, and both feet. She is from a family of diabetic persons, but diabetes is controlled in her own case by therapy with 20 units of insulin daily.*

Paul Beddoe, M.D., Alhambra, Cal.

Answer.—Unfortunately there is no satisfactory treatment of xanthoma diabeticorum. The small lesions may sometimes be surgically excised. It is also true that in any of those cases where diabetes is present the treatment of the diabetes does not necessarily affect a resolution of the xanthomatous infiltrations.

BACTERIOPHAGE TREATMENT OF STAPHYLOCOCCIC INFECTIONS

To the Editor:—*What is the presently accepted opinion on bacteriophage treatment of localized or systemic staphylococcic infections?*

M.D., Florida.

Answer.—There have been extensive studies of bacteriophages. When these were discovered, there was great hope that they would serve therapeutically as an effective antibacterial weapon. This has never been realized. Today there is no practical method of employing bacteriophage therapy in the treatment of staphylococcic infections.

DROWNING

To the Editor:—*A local rescue squad has asked for information about the length of time which a drowning victim may remain submerged with hope of recovery. In other words, how long may a person be under water and still be resuscitated by pulmotor or other means? This question is asked to establish a policy for the use of the rescue squad in future drowning incidents.*

Tom Roe, M.D., Savannah, Tenn.

Answer.—The question is best answered in terms of probability. The following table gives percentages based on data supplied originally by A. Keith and quoted in the book "Adventures in Artificial Respiration" (Karpovich, New York, Association Press, 1953, pp. 258-261):

It seems to be useless to search for an account of the longest known submersion followed by successful resuscitation; samples of such accounts are given by Karpovich together with the reasons why they have little value. We know that the longest a person ever held his breath, as reported by Karpovich (p. 106), under the most favorable laboratory conditions (healthy young student, completely relaxed, having overbreathed to the point of alkalosis and having also inhaled oxygen) was 20 minutes and 5 seconds. An excited person who has worked up an oxygen debt by struggling before submersion would be at a disadvantage on every count; the only thing in his favor would be that cold water would induce some hypothermia and thus slow the process of asphyxiation.

Time Under Water, Min.	Probability of Survival, %	Cases, No.

UNUSUAL MEDICAL QUESTIONS

The Questions and Answers Department of The Journal *receives many letters describing unusual cases. Some of these are too detailed to be printed in the regular Questions and Answers section. From time to time those that represent apparently new or different clinical syndromes or other interesting medical data will be presented in this section of* The Journal.—Ed.

WHEAL AT TUBERCULIN P. P. D. TEST SITE ASSOCIATED WITH ASTHMATIC ATTACK

To the Editor:—*In 1954, a 28-year-old man developed measles complicated by bronchial pneumonia; this was followed by a penicillin reaction, then erythema nodosum, and, two months later, bronchial asthma. Concurrent with an attack of asthma, a wheal often flares in the area of the forearm where he received an intradermal injection of tuberculin P. P. D. in 1950. Could there be any correlation between the wheal and the asthmatic attacks? Has anyone ever attempted desensitization with tuberculin?*

Harold N. Cooper, M.D., San Antonio, Texas.

Answer.—Since no familial history of allergy is given in this case, the origin of the allergy is more uncertain. It could be either truly allergenic or psychogenic. In the latter case, desensitization with histamine phosphate has been used by some physicians. If this treatment proves ineffective, then a true allergenic origin may be considered. Because of the location of residence, histoplasmin sensitization should be considered and, also, a possible sensitization to a host of other cross-reacting acid-fast organisms. Extensive skin testing with products of such organisms may give a clue as to the origin of the sensitization. Desensitization with tuberculin has been used in humans with suspected ophthalmic tuberculous allergy. However, the benefits versus the harm of desensitization have not so far been adequately evaluated. Recent studies in infected animals show that injection of much tuberculoprotein causes a disappearance of circulating antibodies to the tuberculopolysaccharide, a great extension in caseation, and hastening of death. Injection of tuberculopolysaccharide interferes with complement fixation and other immunological processes and also with the natural bacteriostatic activity of serum.

Answer.—It is a fairly common occurrence for a site previously injected with an antigen to flare up under certain conditions. For example, the injection of an antigen (such as ragweed pollen) in one area may cause a reaction in the other arm where the same antigen or a dissimilar one (such as grass pollen) had been previously injected. It has been noted that such a flare-up can occur when the patient inhales the antigen during the season, and it can also happen as a result of ingestion of an allergenic food or drug. Even exposure to cold (swimming) or to heat, or any other physical upset, such as gastrointestinal or emotional upset, may cause the flare-up. The mechanism of this phenomenon is not clear. A possible explanation is that the site which had previously reacted to an antigen had been conditioned to react to other stimuli so that the cells will respond by releasing histamine or other mediators. Desensitization with tuberculin is possible but would not be indicated in this case. If the inquirer has not already done so, he should do everything necessary to determine the allergic or other causative factors for the asthma.

ANSWER.—It is not unusual to see individuals who, for months or years after the original tuberculin reaction has subsided, have redness reappear at the site of the former reaction when the skin becomes cold. It has also been observed that, in an occasional person, administration of a tuberculin test in another location may result in temporary changes of the skin at the site of an old previous reaction. These phenomena have never been satisfactorily explained. It seems doubtful that there is any significant correlation between the wheal and the attacks of asthma. Most persons who have reported various phenomena which have occurred at the sites of old tuberculin reactions have had them in association with other conditions than asthma. There has been a large volume of work done on desensitization with tuberculin, in both animals and people. Hypersensitivity to tuberculoprotein causes this protein to become a violent poison to living tissues. Tuberculoprotein may be introduced into nonsensitized tissues in a large amount without harm. However, if tuberculoprotein comes in contact with sensitized tissues, it is so poisonous to the tissues that, if present in sufficient amount, it results in necrosis. Thus, tuberculoprotein liberated from bacilli in lesions of such organs as lungs and kidneys may result in enough necrotic tissue to leave cavities. Koch originally believed that introduction of tuberculin was valuable in treatment in that it resulted in reactions, including hyperemia, at the sites of tuberculous lesions. He thought that this stimulation was helpful in promoting the healing process. However, later observations revealed that it has the opposite effect in many cases, resulting in spread of the disease and, sometimes, in rapid progression of lesions. Koch used large doses of tuberculin, but some workers thought that smaller doses which would result in only slight reaction at the site of the disease would promote healing. It was observed that by repeating injection of the same amount of tuberculin several times there ceased to be evidence of macroscopic reaction. This was thought to be due to development of "tolerance" to tuberculoprotein. Therefore, the dosage was increased, and tolerance appeared with each successive larger dose of tuberculin administered until an amount was tolerated which would have resulted in serious consequences if it had been administered initially. There were those who so clung to the treatment value of tuberculin on the basis of the reaction that it produced, even though microscopic as they suspected, that its use was long continued in the treatment of this disease. Later, it was well established that it did not result in the imaginary microscopic reaction in lesions after administration of tuberculin but, rather, that it desensitized the tissues. This, therefore, was responsible for the so-called tolerance to tuberculin in the absence of both macroscopic and microscopic reactions in the lesions. The belief that hypersensitivity to tuberculoprotein is an asset in the prevention of clinical lesions or in their healing has been replaced by well-documented evidence that it is a liability in both instances. Tuberculin administrations have been employed for desensitization in asthma when it was thought that hypersensitivity to tuberculoprotein was responsible. However, this apparently is a rare cause for asthmatic attacks, and such treatment should be considered only when all other possibilities have been ruled out as far as possible. There is no harm in desensitizing the tissues of the human body with tuberculin, provided that the dosage is kept below the skin-reaction level at all times. If desensitization is achieved, even to such a low level that 10 mg. of tuberculin will not result in a reaction, it can be maintained only by continuous administrations of tuberculin. If this is discontinued, sensitivity of the tissues returns and remains as long as living tubercle bacilli are present in the body under circumstances which permit liberation of sufficient amount of tuberculoprotein to maintain it.

CORAL SNAKE BITES

TO THE EDITOR:—*I have just read in the Questions and Answers section of* THE JOURNAL *a discussion about poisonous snake bites. However, the very one I wanted to know about, that of the coral snake, was omitted. There has recently been found in this vicinity two coral snakes, the identity of which is certain. Please give information on the exact and specific treatment, particularly the antivenin dose, as well as any special supportive measures. There has been some conflicting opinions among some authorities in regard to ACTH and hydrocortisone sodium succinate. Is it, or isn't it, indicated?*

David Eanes, M.D., Temple, Texas.

ANSWER.—Little is known about the venom of the North American coral snakes (Micrurus). Probably no single physician in the United States has had extensive experience in treating their bites. There are no reports in the literature of "large" numbers of cases. Little is known about the frequency of coral snake bites; however, they are probably rare owing to the snakes' limited geographical distribution and their relatively unaggressive behavior. In Florida, a study of the incidence of snake bites showed that only 5 (2%) of 241 poisonous snake bites were inflicted by coral snakes (Parrish, *Am. J. Trop. Med.* 6:761, 1957). This consultant has personally seen and treated four persons with coral snake bites. These bites all consisted of scratches on the skin from the fangs—there was no deep impregnation of the venom, and no symptoms of venom poisoning developed. These incidents would be classed as "poisonous snake bites without envenomation." No specific treatment was deemed necessary in these cases. The coral snake has very short fangs and usually must "chew" its venom into a human being. Neill reviewed the literature of coral snake bites and reported an additional 21 bites with 4 deaths (*Herpetologica* 13:111, 1957). These cases were investigated by means of a questionnaire. Many of these questionnaires were answered by the family and not by a physician. However, coral snake venom is toxic, and human deaths resulting from coral snake bites have been recorded.

The venom of the coral snake is similar to that of the cobra and is primarily neurotoxic in action. Symptoms include local pain, motor paralysis, muscular twitching, inability to speak clearly, salivation, numbness, and respiratory difficulty. Death usually results from respiratory paralysis. Treatment consists of the usual tourniquet with incision and suction if the bite is seen early. There is a specific antivenin for coral snakes, antielapid antivenin, which is effective for the South American coral snakes (and presumably for the North American coral snakes also). It is manufactured by the Instituto Butantan, Sao Paulo, Brazil. From 10 to 50 cc. is the recommended dose. In general, antivenins for neurotoxic venoms are more effective than antivenins for hematoxic venoms. Note that antivenin (crotalidae) polyvalent, the only snake antivenin manufactured in the United States, is not effective against coral snakes. Other therapy is supportive in nature and is somewhat similar to that used for bulbar poliomyelitis. A tracheotomy, oxygen therapy, and a respirator may tide a patient over respiratory paralysis. Antibiotics and tetanus toxoid and/or antitoxin should be given to prevent infections. Morphine and other narcotics which depress the central nervous system are contraindicated. Central nervous system stimulants, such as nikethamide and caffeine may be tried. Shock should be combated by intravenous administration of blood, plasma, and electrolytes. Cortisone and ACTH do not prevent death in snake venom poisoning but may afford some symptomatic and supportive benefits.

ULCERATIVE COLITIS AND OSTEOPOROSIS

To THE EDITOR:—*A 38-year-old man was recently hospitalized because of an acute compression fracture of T-10. A history of intermittent diarrhea of more than 15 years was obtained. Stools were noted by him as brown, occasionally blood-streaked, and mushy. Roentgenograms revealed ulcerative colitis of the transverse and descending colon and sigmoid, as well as diffuse ileitis involving about 25 cm. of the terminal ileum. The ascending colon and cecum appeared uninvolved. Sigmoidoscopy revealed a granular mucosa in the upper sigmoid only, which on biopsy revealed accumulations of lymph and plasma cells in the mucosa and submucosa with no giant cells, and a diagnosis of nonspecific inflammation was made. Bone survey revealed generalized osteoporosis involving the right femur, tibia, humerus, and spine. There was diffuse demineralization and loss of traveculation, as well as the compression fracture in the thoracic spine. The lamina dura was present. Laboratory findings included the following data: 24-hour urine calcium level (milk-free diet), 164 mg.; serum alkaline phosphatase level, 5.7 Shinowara (S. J. R.) units; sodium level, 143 mEq. per liter; potassium level, 4.5 mEq. per liter; calcium level, 9.2 mg. %; phosphorus level, 3.5 mg. %; stool fat, negative; prothrombin time, 76%; histamine gastric analysis, total 74 degrees, free acid, 60 degrees; glucose tolerance curve, 67, 127, 168, 163, and 72 mg. %; serum carotene 126 I. U. per 100 cc.; thymol turbidity, 3.5 units; sulfobromophthalein, 4.5%; stool guaiac, 1+; serum protein-bound iodine level, 5.5 mcg. %; urea nitrogen level, 11 mg. %; protein albumin and globulin levels, 3.2 and 4.6 Gm.%; hemoglobin level, 14.8 Gm.%; and white blood cell count, 8,650 per cubic millimeter. Could osteoporosis occur secondary to ileitis in this case, with normal serum calcium, phosphorus, and alkaline phosphatase levels? Do abnormal findings on tolerance tests (carotene, glucose) revert to normal in quiescent intervals? Does the absence of gross fat in the stool rule out marked steatorrhea of a degree necessary to produce this picture, or would fat partitions and balance tests of nitrogen aid in the diagnosis? Is folic acid, vitamin B_{12}, or liver therapy useful if there is no anemia or achlorhydria? Is steroid therapy indicated to increase calcium absorption?*

Leonard Breslaw, M.D., Los Angeles.

ANSWER.—The record of this patient contains several unusual features. The segmental ulcerative colitis of the transverse colon with a normal ascending colon and then diffuse ileitis of such a long stretch of ileum is rare. The physical examination and the laboratory data indicate the patient's condition to be rather good. Osteoporosis secondary to an extensive ileitis is possible, but certainly one would expect changes in the calcium and phosphorus levels of the serum. Abnormal findings on tolerance tests may revert to normal when the intestinal condition is quiescent. The absence of gross fat in the stools indicates the absence of a steatorrhea of any marked degree. Further investigations for the cause of the so-called osteoporosis and fracture of the thoracic spine should be undertaken. The possibility of metastatic malignancy might be considered. Folic acid, vitamin B_{12}, or liver would hardly be indicated in a patient with such satisfactory laboratory data. The advisability of the use of steroids is questionable. The case is unusual and warrants further study.

Miscellany . .

FLEMMING PROPOSES LONG-RANGE STUDY OF HEALTH, WELFARE GOALS

Secretary Flemming is interested in getting a long-range study underway of the nation's health, welfare, and education goals and particularly to determine what is the "fair share" of the federal government. He told a press conference:

"I am tired of people pulling figures out of the air on what the federal government ought to do. There is no recognition of state, local, and private responsibilities. All have to share."

While still in the formative stage, the plan for a health survey contemplates a group of consultants along the lines of the Bayne-Jones committee which reported last summer to retiring HEW Secretary Folsom on needs and goals in two areas: medical research and medical school expansion.

Mr. Flemming promised "fullest consultation" with interested organizations in arriving at answers for such questions as (1) time span for achieving goals, (2) how much to spend each year, and (3) how much to be spent through grants in aid.

The HEW, he indicated, was most advanced in its planning for studies in the field of education. Health and welfare studies would follow. Mr. Flemming described the projects as a good example of the "leadership role of the government."

As a preliminary step to his studies, the Secretary is conducting a series of "listening" meetings with heads of national organizations in the health, welfare, and education fields. The first of these was on vocational rehabilitation. Among the proposals aired during the day-long session were these:

1. Creation of a new federal agency for training the severely handicapped for independent living when it becomes apparent they cannot return to employment.
2. Establishment by the federal government of a program of rehabilitating an estimated 500,000 to 750,000 who are jobless because of alcoholism.
3. A requirement that workmen's compensation boards in each state rehabilitate the disabled and not just pay them compensation.
4. The deaf to have access to rehabilitation centers; four-year college courses to be set up for prosthetists.

WHITE HOUSE AGING CONFERENCE HAILED BY HEW UNDERSECRETARY

The White House Conference on Aging set for January, 1961, will have "great significance in advancing" programs for older persons, including those in the medical field. This view was expressed by *Bertha A. Adkins, Undersecretary of the Department* of Health, Education, and Welfare, in an address before the Gerontological Society.

Mrs. Adkins said the conference authorized by the last Congress will not be wholly organized and controlled by the federal government but will be "a great national forum reflecting the knowledge, thinking, and proposals of the greatest possible number of our citizens."

The conference will be under the over-all direction of a national advisory committee composed of outstanding citizens and recognized leaders in gerontology and the fields of economics, education, health, housing, recreation, religion, and welfare. HEW is now collecting names of possible candidates for the council.

Mrs. Adkins noted that funds had been provided to help the states plan for state conference on aging in advance of the Washington conference. Many persons will have an opportunity at the state level to contribute to the state reports which can be brought to the White House meeting.

"It is our hope that these state conferences will be preceded, in turn, by hundreds of community meetings . . . involving individuals, groups, and organizations concerned with the vast array of problems and approaches to all aspects of this whole matter of aging. If this happens, we can have confidence that we are embarking on a new stage of development in creating services for our older citizens," Mrs. Adkins declared.

"If all of us work together—professional people, citizens, and those of us in public life—as individuals and through our organizations, we can inaugurate a real movement toward enriching the added years of life."

The importance of the White House conference was stressed in a separate address by Tol Terrell, past president of the American Hospital Association, to a Washington meeting of the Maryland, District of Columbia, Delaware Hospital Associa-

tion. Mr. Terrell noted the work being done now in helping solve the health needs of the aged. He added that there should be no new approach to providing for the aged (such as the Forand proposal for free hospitalization through social security) until after the outcome of the White House Aging Conference.

NOBEL PRIZE WINNERS IN MEDICINE AND PHYSIOLOGY

The award of the 1958 Nobel Prize in medicine and physiology to three American scientists has prompted a comment from the Department of Health, Education, and Welfare. All three, according to Secretary Flemming, have been closely associated for many years with research supported by the National Institutes of Health. The secretary cited it as an "excellent example of what the federal government can do to help" scientists.

Dr. Joshua Lederberg of the University of Wisconsin has been receiving an NIH grant for 10 years. Dr. Lederberg is a member of the newly formed Genetics Study Section of NIH, having been a member of the Morphology Study Section from 1949 to 1953. His current grant is from the National Cancer Institute, for $13,800.

Dr. Edward Tatum of the Rockefeller Institute for Medical Research is a member of the Division of General Medical Sciences Genetics Training Committee and has received grant support from NIH since 1951. His current grant is $14,145, from the National Cancer Institute.

Dr. George Beadle, California Institute of Technology, was the first scientist to deliver a Dyer Lecture at NIH and is now receiving a National Heart Institute grant, working in experimental biology and genetics. His current project is expected to receive support until 1961; his current grant is $54,148.

HEW estimates that nearly half of the country's medical research is supported by NIH grant programs and that they involve some 7,000 grants this year. Awards are made upon recommendation of some 700 nonfederal advisers who review applications for grants as members of study sections and advisory councils.

PRELIMINARY PLANS FOR NATIONAL LIBRARY OF MEDICINE

Architects have submitted preliminary plans for the construction of the National Library of Medicine to the Public Buildings Service, which must give its approval before work proceeds. Final working drawings are expected to be ready in December, according to the Public Health Service.

The 7 million dollar stucture will be built on the grounds of the National Institutes of Health at Bethesda, Md. There will be 232,000 sq. ft. of space on five levels, three of which will be below ground level. The design is the work of R. B. O'Connor and W. H. Kilham Jr., of New York City. The last Congress voted funds to replace the 71-year-old building which houses the largest medical library in the world.

PHS officials are hopeful that ground will be broken next spring for the library. The building is expected to be completed in 1961, the 125th anniversary of the library's founding.
